

## MEMORANDUM

### LABOR REFORM AS A CATALYST FOR GROWTH

#### **I. Introduction**

Puerto Rico faces tremendous challenges. The economy has been shrinking for more than ten years and the Government has amassed over \$70 billion in outstanding debt liabilities and over \$50 billion in unfunded pensions liabilities. Hurricanes Irma and Maria made the situation even more unbearable.

As the Executive Summary of the New Fiscal Plan for the Commonwealth of Puerto Rico (the “New Fiscal Plan”) outlines, the people of Puerto Rico need and deserve plentiful good jobs, a dynamic and prosperous economy, affordable and reliable electricity, and an efficient and responsive public sector—but have been deprived of such for more than a decade. Instead, since 2005, the number of people living under the poverty level has increased, the economy has shrunk, electricity has remained expensive and unreliable, labor market regulations have remained burdensome—hindering job creation for the people—and the public sector has provided declining levels of service at a high cost to citizens. These problems predate Hurricanes Irma and Maria and will continue to plague Puerto Rico long after it recovers from the storms unless the necessary actions are taken.

The Island faces immense challenges with labor force participation and preparedness.<sup>1</sup> As exemplified on **(Exhibit 1)**, the Island’s formal labor force participation rate is only ~40%, far from the U.S. mainland average (63%) or even the lowest-ranked U.S. state (West Virginia, 53%), and well below other Caribbean islands. In fact, according to World Bank data, Puerto Rico’s labor force participation rate is currently 7<sup>th</sup> lowest in the world and has never ranked higher than the bottom 20 out of more than 200 countries and territories surveyed.<sup>2</sup> Moreover, Puerto Rico’s youth

---

<sup>1</sup> It is tempting to conclude that, due to Puerto Rico’s large informal labor market, the true labor force participation rate is far higher than the official statistics that policymakers rely upon. However, research by Maria Enchautegui (University of Puerto Rico) and Richard Freeman (Harvard University) concludes that this is unlikely to be the case. Many individuals who participate in the informal labor market are likely described in household surveys as self-employed, and the self-employed are included when those survey data are used to calculate the labor force participation rate. For this reason, as well as based upon a survey conducted among male Puerto Rico residents, Enchautegui and Freeman conclude that the official labor force participation rate understates the true labor force participation rate by only a few percentage points. Enchautegui, Maria, and Richard B. Freeman. “*Why don’t more Puerto Rican men work? The rich uncle (Sam) hypothesis.*” Working paper No. w11751. National Bureau of Economic Research, 2005.

<sup>2</sup> Puerto Rico ranking has never surpassed 215th out of the 232 countries, states, and territories tracked by The World Bank Group since The World Bank Group began collecting data in 1990.

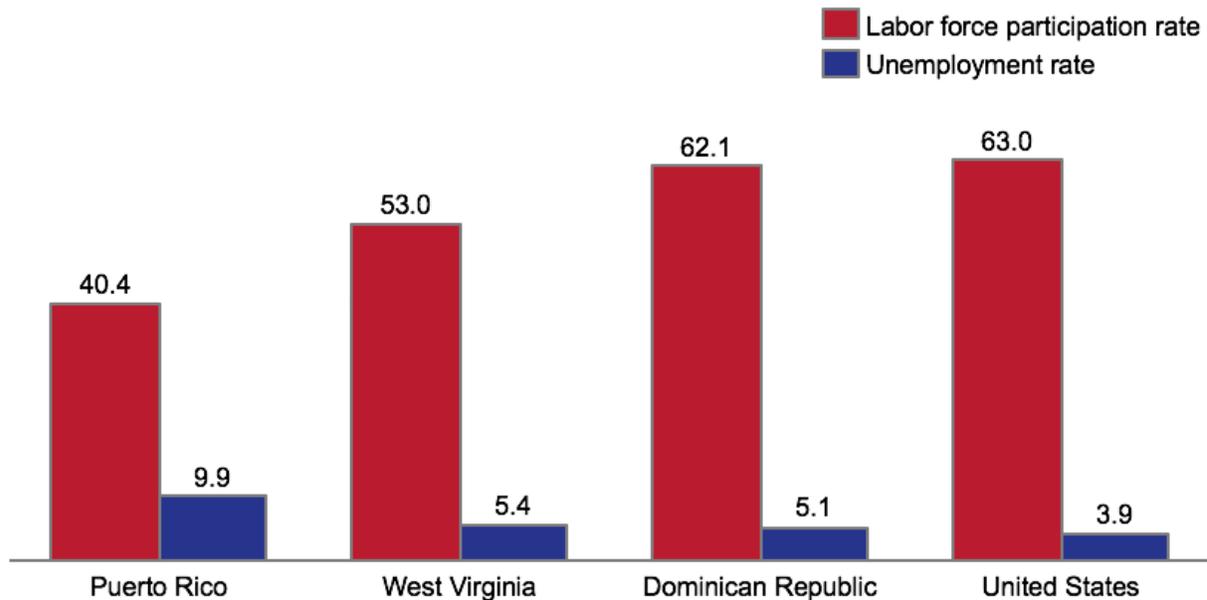

**Memorandum: Labor Reform as a Catalyst for Growth**

Page 2 of 35

unemployment rate is 23.8%, almost double the world average (13.8%) and more than double the U.S. average (10%).<sup>3</sup>

**Exhibit 1: Labor Force Participation and Unemployment Rates<sup>4</sup>**

Labor force participation rate and unemployment rates, %

Low labor force participation in Puerto Rico is a function neither of Hurricane Maria nor the economic downturn that began in 2006. The Statement of Motives of Act No. 4 of 2016 indicates that as of October 2016, the labor participation rate of Puerto Rico was at 39.8%, while it was at 62.8% for the United States. The reality in the Island contrasted dramatically with that prevailing in 1950, when the labor participation rate of Puerto Rico was 57.9% and that of the United States was 60%. Low rates of employment are a long-term structural problem that can be addressed only through significant changes to public policy. The PROMESA legislation expressed Congress’s opinion that “any durable solution for Puerto Rico’s fiscal and economic crisis should include permanent, pro-growth fiscal reforms...” The labor and welfare reforms discussed herein form part of that commitment to fulfill the stated goals of PROMESA.

Low rates of employment contribute to Puerto Rico’s low incomes and its high rate of poverty. As the studies and analyses provided below demonstrate, were Puerto Rico to increase its labor force

Page 3 of 35

participation rate even to that of the lowest mainland state – West Virginia – household incomes would rise significantly, poverty would fall and many of the government’s budget problems would be addressed. Approximately 60% of the gap in median household incomes in Puerto Rico and the poorest mainland state, Mississippi, is accounted for by Puerto Rico’s far lower labor force participation rate.<sup>5</sup>

Since 2000, about 600,000 Puerto Ricans have relocated to the state of Florida, many in search of employment opportunities.<sup>6</sup> Florida is an at-will employment state and does not require employers to provide any paid vacation or sick days or Christmas bonus.<sup>7</sup>

About one-quarter of Puerto Ricans work informally. The informal labor market, which is far larger in Puerto Rico than anywhere in the rest of the United States, is driven in part by labor laws which make it uneconomical to hire employees with full benefits and job protections.<sup>8</sup> The informal economy diminishes Puerto Rico’s tax base, from which the Government funds public services. More importantly, employees in the informal sector currently do not have access to legal employment rights and to Social Security for the future.

Unless Puerto Rico substantially increases its labor force participation and employment, incomes will always fall far below mainland states and outmigration will continue to draw Puerto Ricans away from the island of their birth. **While many other reforms are integral to making these improvements, increasing labor force participation may be the single most important objective for long-term economic well-being in Puerto Rico.**

---

<sup>5</sup> Calculated using Mississippi’s (the poorest mainland state) labor force participation rate of 55.6% and Puerto Rico’s labor force participation rate of 40%; and MS’s median household income of \$39,218 and PR’s of \$19,606. By multiplying PR’s median household income by 55.6/40, the product is \$27,252, leaving a cap of only \$11,966.

<sup>8</sup> Estimates of the size of the informal economy are 15-20% of GNP, correlating to \$10-14 billion, pre-Maria. Rates derived from “Congressional Task Force on Economic Growth in Puerto Rico,” U.S. Congress, December 20, 2016. <https://www.finance.senate.gov/imo/media/doc/Bipartisan%20Congressional%20Task%20Force%20on%20Economic%20Growth%20in%20Puerto%20Rico%20Releases%20Final%20Report.pdf>, p. 11; GNP is FY2016 projected (\$70.1B) from “Statistical Appendix of the Economic Report for the Governor and Legislative Assembly,” Government Development Bank for Puerto Rico, 2018. <http://www.gdb.pr.gov/economy/statistical-appendix.html>.

**The manner in which labor regulations are structured – and the costs and risks they impose as part of normal business transactions – harms Puerto Rico’s ability to create good-paying jobs in the private sector. These costs and risk reduce the economic growth and future revenues projected in the New Fiscal Plan. Therefore, fostering a regulatory environment conducive to increasing labor participation rates is essential to fulfilling fiscal projections.** More importantly, higher employment levels and better-paying jobs are crucial to transforming Puerto Rico’s economy from one that trends downward to one that has a brighter future.

On April 19, 2018, pursuant to 201(e)(2) of PROMESA, the Oversight Board voted to certify the fiscal plan for the Commonwealth of Puerto Rico, pursuant to Section 201(d)(2) of PROMESA (the “New Fiscal Plan”). On April 24, 2018, pursuant to Section 201(e)(2) of PROMESA, the Oversight Board delivered to the Government of Puerto Rico, a compliance certification for the New Fiscal Plan as well as copy of the New Fiscal Plan.

An integral component of the New Fiscal Plan is the adoption of certain limited changes to Puerto Rico’s labor laws, the establishment of a local Earned Income Tax Credit (EITC), and the creation of certain work requirements and work bonuses for the participants in the Nutritional Assistance Program (PAN).

On May 21, 2018, the Board agreed to focus labor reform on transforming Puerto Rico into an “employment-at-will” jurisdiction, the establishment of a local Earned Income Tax Credit (EITC), and the creation of certain work requirements and work bonuses for the participants in the Nutritional Assistance Program (PAN). The adoption of these limited labor market reforms is projected to generate \$319 million in additional revenues collected by the Government of Puerto Rico over the five-year period covered by the Plan. Moreover, by implementing labor reform, Puerto Rico will have access to reinvest over \$700 million to promote further economic development and reduce the risk of reform implementation by investing in infrastructure projects and recovery, digital reform, implementation of ease of doing business reforms, and procurement reform. In addition, given the ongoing recovery after hurricanes, this reinvestment will include a Municipality Recovery Fund and into the UPR’s needs-based scholarship fund. This reinvestment, along with the PAN work requirement and EITC, will bolster employment as well as ensure that those entering the workforce are more prepared to earn higher wages.

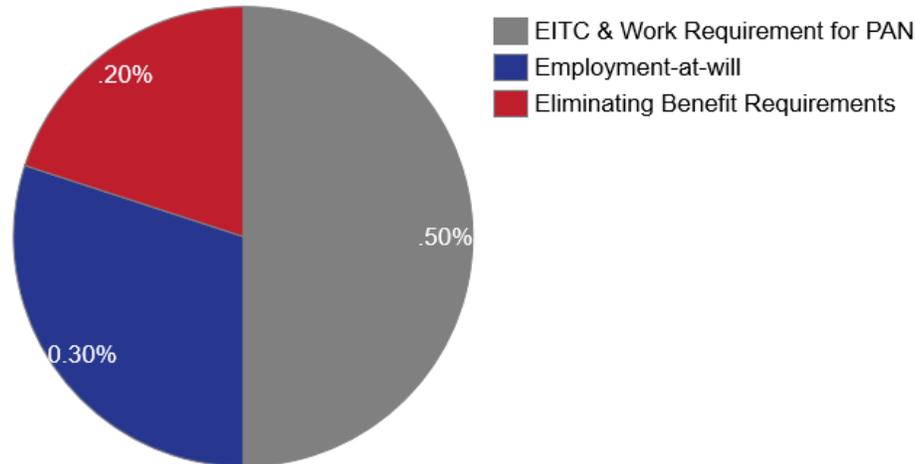

The Oversight Board’s economist has scored the monetary value of the overall Labor Reform Package contained in the New Fiscal Plan at one (1) full percentage point of permanent growth, about half of which would come from the labor supply side through the EITC and limited work-requirement for PAN, and half from the labor demand side. Consistent with the Italian experience and the IMF study noted below, it was estimated that about 0.3% points would come from easing employment protection (*i.e.*, implementing an “employment-at-will” regime) and 0.2% points from eliminating benefit requirements, such as generous paid vacation. As seen in **(Exhibit 2)**, and given the New Fiscal Plan accommodation agreed to with the Governor, the scoring of the labor reform package presently envisions a 0.80 percentage point of permanent growth.<sup>9</sup>

---

<sup>9</sup> Wolfe, Andrew, “Derivation of 0.3%-point increase in growth from the implementation of “employment-at-will””

**Exhibit 2: Estimated Incremental GNP Growth from Labor Reforms**

**The Oversight Board believes the measures required in the Labor Package of the New Fiscal Plan will improve the vibrancy of the local labor market; make Puerto Rico more competitive and attractive for job-creating investments; promote more hiring within the formal economy; and produce more revenue to the government.**

***None of the provisions of the labor reform place workers in Puerto Rico at a disadvantage in comparison to workers on the mainland. None of the provisions of the labor reform strip workers in Puerto Rico of rights enjoyed by workers on the U.S. mainland. None of the provisions create incentives for workers to abandon the island seeking greater protections under state laws- since no state grants protections beyond what is contemplated by the labor reform.***

The reforms contained in the New Fiscal Plan have been used effectively to turn around economies in many countries. They provide a realistic and achievable blueprint for success, with proven methods for growth, restoring business confidence, improving competitiveness, ending the debt crisis, and attracting the investment needed to transform the Island. This roadmap for recovery will produce more jobs, better living conditions and improve educational and healthcare outcomes for Puerto Rico’s residents.

The analyses, data, and studies included in this memorandum intend to provide information supporting the adoption of human capital and labor reforms for the benefit of the people of Puerto Rico. **Given the recent accommodation to the New Fiscal Plan, the numbers reflected in this memorandum will be conformed to reflect final technical adjustments in the recertification of the New Fiscal Plan.**

## **II. Employment Laws Matter**

Puerto Rico's historically low levels of formal labor force participation cannot be attributed to any single factor, but a range of public policies have served to reduce employment on the Island. Puerto Rico has by far the most generous mandated employer benefits in the U.S., which increase the cost of hiring employees. Unlike Puerto Rico, no mainland state mandates any paid vacation and few mandate even a modest amount of sick leave. No state requires employers to pay a Christmas bonus. Thus, it can be more expensive to employ a low-wage worker in Puerto Rico than on the mainland, making Puerto Rico less competitive in labor-intensive sectors such as tourism.

Economists have documented that when employers are required to provide an employee benefit, those employers will tend to recoup the costs of those benefits by reducing the wages paid to employees.<sup>10</sup> When employers are prevented from reducing wages to offset costs of mandated benefits, as may be the case with a minimum wage worker, they may choose to reduce the number of workers they hire. Thus, it is reasonable to assume that Puerto Rico's high levels of mandated employer-paid benefits reduce both wages and employment relative to a scenario in which such benefits were not required.

Likewise, there is evidence that employer benefit costs can increase the size of the informal labor market, where income is not reported, and such benefits need not be provided.<sup>11</sup> About one quarter of Puerto Rican workers participate in the informal economy according to Estudios Técnicos,

---

<sup>10</sup> This has been shown to be true with employer-paid Social Security taxes, health coverage, maternity leave, and other benefits. For instance, the Congressional Budget Office and the Social Security Administration both assume that an increase in Social Security payroll taxes levied on employers would result in a roughly dollar-for-dollar reduction in employee wages. Likewise, when the Affordable Care Act ("Obamacare") was projected to reduce the rate of growth of employer health care costs, the Social Security and Medicare Trustees assumed that this would be reflected in increased wages paid to employees. Gruber and Krueger (1991) found that employer costs for workers compensation insurance are largely shifted to employees via lower wages. Gruber (1994) found that when employers were required to provide maternity health benefits to employees, wages for employees declined by a similar amount. Prada et al (2017) found that when Chile required employers to provide free child care, wages for women declined by 9 to 20 percent. Kolstad and Kowalski (2016) found that when Massachusetts required employers to provide health insurance, wages for employees declined by an amount similar to the health premiums paid by employers. (Gruber, Jonathan, and Alan B. Krueger. "The incidence of mandated employer-provided insurance: Lessons from workers' compensation insurance." *Tax Policy and the Economy* 5 (1991): 111-143. Urzúa. *The effect of mandated child care on female wages in Chile*. No. w21080. National Bureau of Economic Research, 2015. Kolstad, Jonathan T., and Amanda E. Kowalski. "Mandate-based health reform and the labor market: Evidence from the Massachusetts reform." *Journal of Health Economics* 47 (2016): 81-106.)

<sup>11</sup> Kugler et al (2017) found that a reduction in employer payroll taxes in Colombia reduced the size of the country's informal labor market. Kugler, Adriana, Maurice Kugler, and Luis Omar Herrera Prada. "Do payroll tax breaks stimulate formality? Evidence from Colombia's reform." No. w23308. National Bureau of Economic Research, 2017

**Memorandum: Labor Reform as a Catalyst for Growth**

Page 7 of 35

substantially higher than any mainland state.<sup>12</sup> The informal economy is detrimental to the Island because it diminishes Puerto Rico's tax base, from which the Government funds public services. And more importantly, those working in the informal sector currently do not have access to certain legal, financial, and labor rights and to Social Security for the future.

Puerto Rico law imposes upon an employer costly mandatory employer-provided benefits that are not comparable to those prevailing in other jurisdictions under the U.S. flag. These compulsory benefits effectively increase labor costs. Moreover, the compulsory vacation and sick leave benefits constitute payments for time not worked. In addition to these above market "labor cost" factors, Puerto Rico lacks "at-will employment," which would permit employers to manage their business and make non-discriminatory personnel decisions without being exposed to substantial monetary risks. While there are variations in labor laws among the 50 mainland states, 49 of them follow the "at-will employment" legal rule (**Exhibit 3**). This rule avoids court's "second guessing" the validity of legitimate and non-discriminatory discharge decisions. The only state that has departed from this regime is Montana, and that statute was enacted to *reduce* the monetary exposure Montana state courts had imposed in wrongful discharge claims.

The impact of Puerto Rico’s labor regulatory regime on future private sector economic growth has already been recognized by the Government of Puerto Rico with the enactment last year of the *Labor Transformation and Flexibility Act*, Law No. 4-2017. The *Statement of Intent* of Law No. 4 sets forth significant labor economic findings which justified the modification of several employment laws.

The extensive legislative findings contained in Law No. 4’s *Statement of Intent*, coupled with the detailed Senate and the House of Representative’s *Committee Reports*, unambiguously recognize the burden of certain Puerto Rico employment laws on efficient labor markets and job destructive effects of several of these laws. The present Administration’s “Government Plan” also recognized the interrelation between Puerto Rico’s low employment levels and its labor regulatory structure.

**Memorandum: Labor Reform as a Catalyst for Growth**

Page 9 of 35

All of these are in line with prior observations made by local and internationally recognized economists regarding the adverse impact of various Puerto Rico labor laws.<sup>13</sup>

The Government of Puerto Rico has recently made strides to improve labor market conditions with the *Labor Transformation and Flexibility Act* (Act 4-2017) in January 2017. Notwithstanding such reforms, Puerto Rico's labor laws remain by far the most burdensome in the U.S.

The question presented is *not* whether the level and structure of Puerto Rico's mandatory benefit and discharge laws adversely impact the island job creation ability. Rather, the question is whether the Law No. 4 implemented a sufficient degree of labor reform to achieve its stated objective of transforming Puerto Rico into "an attractive jurisdiction to establish business and create job opportunities; to foster growth in the level of jobs in the private sector; and to offer new job opportunities to unemployed people." *Statement of Intent*, p.3. **The Oversight Board's estimation is that Law No. 4 did not implement the extent of labor reform required to alter the existing structural obstacles to job creation and retention. Accordingly, additional actions are necessary if Puerto Rico intends to compete with other jurisdictions within the United States to attract job-creating investments.**

Notwithstanding Law No. 4's reforms, Puerto Rico's labor laws remain by far the most burdensome in the U.S. The Island still requires yearly Christmas bonuses of \$600 (or \$300 for small employers); typically mandates up to 27 days of paid leave per year;<sup>14</sup> and exposes employers to substantial severance payouts, therefore imposing costs and regulatory burdens that reduce employment, wages and economic opportunity.

After little over a year of the approval of the *Labor Transformation and Flexibility Law*, a review of the impact of that legislation shows there is a need to make deeper structural reforms, in order to make Puerto Rico as attractive a location to create jobs as the continental states. In the Oversight Board's estimation, there is a reasonable basis to conclude that Puerto Rico's wrongful discharge statute, coupled with other mandatory benefit legislation that imposes labor costs beyond competitive levels, adversely impacts job growth and the Government's future revenue projections.

The Oversight Board invites the Puerto Rico Legislature to recognize that the private sector labor relations regime in the continental states has remained consistent on the principle that, except for reasons prohibited by law, hiring and employment tenure should be free from government control through dismissal laws. The *Employment-At-Will* system has been widely examined. At-will

---

<sup>13</sup> Law No. 4's *Statement of Intent*, expressly cites Dr. James Tobin (Nobel Prize in Economics, 1981); Dr. Anne Krueger (former first deputy managing director of the International Monetary Fund); Dr. Elías R. Gutiérrez and economist Gustavo Vélez.

<sup>14</sup> Puerto Rico maintains a complex regimen of mandatory decrees that dictate different vacation and sick leave accrual rates, some of which establish up to 18 vacation and 18 sick leave days per year. In 1995 a law was passed to cap vacation and sick leave accrual rates at 15 and 12 days, respectively, but employees hired before August 1, 1995 were grandfathered if they previously were entitled to higher rates. Most employees in Puerto Rico are covered by mandatory decrees that grant 15 vacation and 12 sick leave days per year.

employment ensures that the employment tenure is based on productivity and good conduct and prevents any undue government intrusion in essential business decisions.

### **III. “Back to Work” Welfare Policies**

In addition to the Island’s labor laws, Puerto Rico residents may also face disincentives to participate in the formal labor market due to rules attached to various welfare benefits, including the Nutritional Assistance Program (PAN), Mi Salud (Medicaid), Section 8 public housing, TANF, WIC, and other programs.

These benefits are sometimes stereotyped with a claim that “welfare pays more than work.” But the issue is really that working in the formal sector can cause punitive reductions in the transfer benefits the household would receive were it not to work in the formal sector. The problem occurs because when welfare beneficiaries work in the formal sector and receive earnings, this triggers a reduction in their benefits. The phase-out of government transfer benefits as earned income increases acts as a tax to disincentivize formal employment, as effective hourly wage (income received by working minus the loss of benefits) can be substantially lower than the formal hourly wage received.

In a 2015 report, the Congressional Budget Office noted that

The effective marginal tax rate is the percentage of an additional dollar of earnings that is unavailable to an individual because it is paid in taxes *or offset by reduced benefits from government programs*. That rate affects people’s incentives to work. In particular, when marginal tax rates are high, people tend to respond to the smaller financial gain from employment by working fewer hours, altering the intensity of their work, or not working at all.<sup>15</sup>

This is precisely the problem faced in Puerto Rico, but it is very likely to be worse on the Island than in mainland states.

While transfer benefits in Puerto Rico are not more generous than on the mainland in dollar terms, they *are* more generous relative to the wages generally available for individuals currently receiving transfer benefits. For instance, monthly food stamp benefit levels are similar in Puerto Rico and mainland, but the market wages available to a food stamp beneficiary in Puerto Rico are substantially lower. Thus, the trade-off between work and welfare in Puerto Rico is not as attractive as on the mainland. Thus, the effective marginal tax rate on low-income Puerto Rico residents from entering the workforce is likely to be higher, perhaps substantially so, than on the mainland.

It is difficult to quantify how large such disincentive effects may be due to limitations on the data available. Different individuals entitled to different sets of benefits face different incentives should

<sup>15</sup> Congressional Budget Office. “Effective Marginal Tax Rates for Low- and Moderate-Income Workers in 2016.” November 19, 2015.

**Memorandum: Labor Reform as a Catalyst for Growth**

Page 11 of 35

they work. Still, it is reasonable to conclude that for many welfare beneficiaries, formal sector work may sometimes do little to increase household incomes.

For individuals receiving food stamps, Mi Salud, TANF and public housing, it often makes little financial sense to work at the minimum wage in the formal sector. For a full-time minimum wage worker the loss of benefits will offset most or all income received from work, leaving the household no better off.<sup>16</sup> Add in the complications and costs for those with children to be working outside the home and the incentives for breadwinning family members to work in the informal sector only become magnified.

Though few Puerto Rico residents receive all these benefits,<sup>17</sup> even receipt of a single type of benefit can alter incentives to engage in the formal workforce. For instance, a single mother with two children and annual income below \$4,900 is eligible to receive approximately \$4,229 in annual PAN (“food stamp”) benefits. But should that individual work 35 hours per week at the minimum wage, her annual earnings of \$12,180 would cause her to lose eligibility for food stamps. Net of taxes on her earnings, working full-time would increase her household’s annual income by only \$7,002, equivalent to an hourly wage of only \$3.86. Under those conditions, some individuals may choose not to work in the formal labor market, especially if they have to pay for child care

Even when TANF and Section 8 housing benefits are excluded, monthly income paid to a minimum wage worker with two children is only \$329 greater than what he or she could receive from government benefits.<sup>18</sup> In this example, effective hourly pay (the amount received from working more than what the individual could receive from government benefits without working) is only about \$2.35.

Mainland states face many of these same incentive problems, which they address in two ways. First, residents of mainland states are eligible for the Federal Earned Income Tax Credit (EITC), which provides a partial refund against Federal income taxes for eligible low-income workers. Many states supplement the Federal EITC to increase net incomes to individuals who work. By increasing the reward to work, the EITC has been shown to increase labor force participation.<sup>19</sup> However, because Puerto Rico residents do not pay Federal income taxes they are not currently eligible for the Federal EITC.

<sup>19</sup> See Eissa, Nada, and Jeffrey B. Liebman. “*Labor supply response to the earned income tax credit*.” *The Quarterly Journal of Economics* 111, no. 2 (1996): 605-637

Likewise, the Federal Government requires that food stamp programs on the mainland (Supplemental Nutrition Assistance Program, “SNAP”) contain a work requirement. In general, working-age SNAP beneficiaries on the mainland must register for work, cannot turn down a job if offered, and may be required by the state to attend education or work training classes. In addition, Federal law requires that non-disabled adults without dependents must work, attend education, or volunteer at least 20 hours per week to maintain eligibility for benefits. Federal law requires that individuals who fail to satisfy these work requirements lose benefits for at least one month for the first instance, three months for the second instance and six months for the third violation. States are allowed to set more stringent penalties, up to and including permanent disqualification from benefit receipt. Roughly half the states adopt the federal penalties for violating work requirements and half have stronger penalties.

Puerto Rico’s labor and welfare laws may help explain why, despite the Island’s natural beauty, attractions and ease of access from the U.S. market, employment in tourism-related industries is low. According to the U.S. Bureau of Labor Statistics (BLS), Puerto Rico employs only 80,000 individuals in the leisure and hospitality industries – 10,000 fewer tourism-related jobs than the state of Nebraska, which lacks Puerto Rico’s natural assets and has an overall population over one-third smaller than Puerto Rico.

But there is a positive aspect to these findings. **If Puerto Rico’s labor and welfare policies contribute to low levels of employment, low incomes and high poverty rates, then adopting pro-employment policies can increase job availability and incomes in Puerto Rico.** The Board does not claim that labor and welfare reform by itself will fix all of Puerto Rico’s myriad economic problems, and even less so that a single aspect of labor and welfare reform is a cure-all. But without higher labor force participation Puerto Rico is not a viable economic entity; its ability to service its debt and return to capital markets will be reduced, poverty will remain high and outmigration will continue to sap the island of its population.

#### **IV. Future Vision for the Puerto Rico Labor Market**

Changes to labor and welfare laws are controversial and can be disruptive. Nevertheless, dramatic changes to Puerto Rico’s labor market policies are necessary to provide opportunity for a greater standard of living at home, reversing the Island’s history of high poverty, constrained budgets, and pressure for young Puerto Ricans to leave their home for the mainland.

To ensure Puerto Rico can provide opportunities for its people for years to come, structural reforms must make it easier to hire, encourage workforce participation, and enhance student outcomes and workforce development opportunities to ensure a pipeline of prepared and appropriately-skilled individuals.

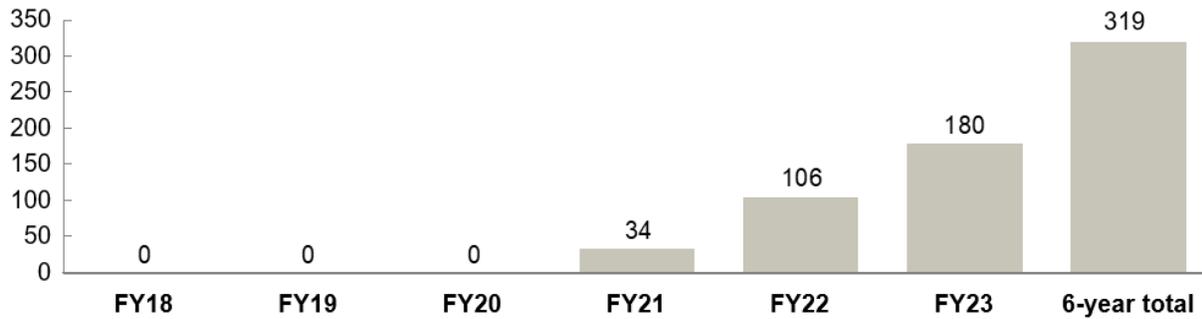

If Puerto Rico were to aim to increase the labor force participation rate to 47% and reduce the youth unemployment rate to 20.2% by FY2023, Puerto Rico would close roughly half the current gap between Puerto Rico and the lowest U.S. state (West Virginia). By achieving these goals, the Government can increase household incomes, cut the poverty rate and reduce incentives to emigrate to the mainland. Moreover, successful labor market reforms are projected to yield

approximately \$39 billion in additional revenues by FY2048 and over ~\$319 million from FY2018-23 (Exhibit 4).

**Exhibit 4: Labor Reform Surplus in the New Fiscal Plan Period**

Labor Reform Surplus, \$M

**V. Structural Reform Initiatives to Change Labor Conditions**

Labor market reforms will increase the availability of jobs while increasing incentives and preparedness to work. To accomplish this broad-based reform, the Government must implement flexible labor regulations, reform welfare including an EITC for low-income workers and a work requirement for able-bodied PAN beneficiaries, and implement programs to develop critical skills in the workforce.

**a. Flexible labor regulations by becoming an employment “at-will” jurisdiction**

Puerto Rico lacks “at-will employment.” This is the regime that applies to job termination decisions in 49 mainland states. At-will employment regimes reduce the risks and operational costs when an employer needs to dismiss an employee for reasons of performance, conduct or workforce reduction.

While some employees benefit from Puerto Rico’s lack of at-will employment, excessive employment protections make it more costly and risky to hire an employee. There is significant research backing this conclusion.

Both Puerto Rico and the U.S. Virgin Islands maintain wrongful discharge laws and both jurisdictions maintain unemployment levels that consistently exceed double the national unemployment rates. And Puerto Rico law is far more burdensome than U.S.V.I. law since it does not exempt small employers and it regulates dismissals resulting from workforce reductions due to economic hardship or the cessation of business operations.<sup>20</sup>

Puerto Rico’s Law No. 80 *does not* prohibit any type of discharge. However, it is based on the premise that, even when a discharge decision is not motivated by illegal reasons, the government should be

<sup>20</sup> 24 V.I.C. §76(c).

**Memorandum: Labor Reform as a Catalyst for Growth**

Page 14 of 35

able to “second guess” an employer’s managerial decision to terminate the employment of a worker for reasons of unsatisfactory conduct, substandard performance or lack of competence. Moreover, when due to periodic economic cycles the employer needs to reduce the size of its workforce, Law No. 80 dictates the manner in which an employer must select who should be laid off and who should be retained. This government intervention in important business decisions is accomplished through the imposition of steep monetary penalties.

Puerto Rico’s Wrongful Discharge Law has an adverse effect on an employer’s ability to operate efficiently. The law imposes significant costs, in terms of the monetary amount imposed as a severance payment, as well as litigation costs, in the event that non-payment of the severance is challenged in court. Ultimately, even when the “just cause” for termination is litigated, the uncertainty of the outcome in court tends to result in discharge payments and the imposition of attorney’s fees.

In short, in Puerto Rico, every employment termination decision exposes a business to significant costs. And since an employer cannot know ahead-of-time which employees may in the future be dismissed, every hiring decision carries risks. Substantial research show that firms take those risks into account when hiring employees and react in ways that harm unemployed or less-skilled workers who most need jobs.

For over four decades the potential monetary exposure in wrongful discharge claims was the payment of one month’s salary or less. This began to change in 1976, with the enactment of Law No. 80, which added one (1) week’s salary per year of service to the severance payment. More significantly, Law No. 80 limited the reasons to justify a discharge without having to incur in the severance payment. Over the years, the monetary amount of the severance payment has increased. In the year 2005 the severance payment increased dramatically, as follows:

- During the first five (5) years of service: 2 month’s salary, plus 1 weeks’ salary for each year of service;
- From five (5), but less than fifteen (15) years of service: 3 month’s salary, plus 2 weeks’ salary for each year of service; and
- Fifteen (15) or more years of service: 6 months’ salary, plus 3 weeks’ salary for each year of service.

With the approval of *Labor Transformation and Flexibility Act* the Government of Puerto Rico recognized that the third tier of the severance formula (15 or more years of service) had a chilling effect on an employer’s ability to operate its business and, therefore, was detrimental to Puerto Rico’s competitiveness. Accordingly, a uniform severance payment was established, based on the *second tier* of the prior formula and subject to a cap of nine (9) month’s salary. However, the Legislature limited this new severance formula to only employees hired *after* January 26, 2017.

If the new Law No. 80 compensation structure was deemed a better balance, it should have applied to all employees.

Further, by maintaining the prior compensation formula for employees hired before January 26, 2017, during the first five years of service new employees have *higher* severance payments. Accordingly, during the first years after the approval of Law No. 4, a discharge of a new employee

**Memorandum: Labor Reform as a Catalyst for Growth**

Page 15 of 35

entails a greater cost than the discharge of an employee hired shortly before the enactment of Law No. 4.

Upon further review of the Law No. 4 amendments to Law No. 80, the Oversight Board finds they are insufficient to remedy the statute's adverse effect on the ability to do business and hire employees in Puerto Rico. The Oversight Board is confident that from a micro and macroeconomic perspective, the adoption of an "at-will" employment regime is the most efficient manner to address job termination decisions. By taking such legislative action businesses and employees in Puerto Rico would be subject to the same labor market rules that are applicable to their counterparts in the mainland states. Notwithstanding this change, employees in Puerto Rico will continue protected by multiple anti-discrimination laws, as are employees on the mainland.

Adopting in Puerto Rico the "at-will" employment regime that prevails in the U.S. mainland will assist in reducing long term unemployment in the private sector and increase the hiring of workers as permanent, rather than temporary employees. Moreover, adoption of this regime should assist in attracting job-creating investments.<sup>21</sup> This, in turn, will increase revenues to the Government.

This is not the first-time changes to the severance regime has been recommended. During recent years the adverse economic impact of Puerto Rico's general dismissal law has been subject to scrutiny. The Krueger Report, which was commissioned by the Government of Puerto Rico, recommended that Puerto Rico regulate discharge decisions with rules more similar to those prevailing in the U.S. mainland.<sup>22</sup> Subsequently, the *Working Group for the Fiscal and Economic Recovery of Puerto Rico Pursuant to Executive Order 2015-022*, recommended that Law No. 80 apply only to "non-exempt" employees and that the maximum compensation be limited to six (6) month's salary.<sup>23</sup>

While some employees benefit from Puerto Rico's lack of at-will employment, excessive employment protections make it more costly and risky not only to dismiss, but also to hire, an employee. There is evidence that such job protection laws lower employment opportunities.

<sup>23</sup> Puerto Rico Fiscal and Economic Growth Plan (September 9, 2015), at 22.

For example, studies have found that laws restricting an employer's ability to dismiss or imposing significant severance costs have the effect of reducing employment levels or increasing long term unemployment, particularly in labor-intensive industries.<sup>24</sup>

In U.S. states, a study found that expanding unfair dismissal protections caused employers to shift away from using less-skilled workers and toward greater use of capital investments and more-skilled labor.<sup>25</sup> Simply, the risks and costs related to dismissal decisions tend to chill an employer's inclination to hire new employees, particularly younger employees.<sup>26</sup> This results in higher periods of unemployment for those members of the workforce who are not employed.<sup>27</sup>

Other research finds that when firms cannot easily dismiss unsatisfactory employees, they will not hire employees who do not already have a job- as unemployed workers are seen as a greater risk.<sup>28</sup> Still other research concludes that stronger employment protections cause businesses to favor more educated employees, who are seen as less risky to hire than less educated workers.<sup>29</sup>

Moreover, there is significant evidence that employers, in order to avoid risks and costs related to dismissals laws, will increase outsourcing or utilization of temporary employees.<sup>30</sup>

Excessive employment protections may also reduce the productivity of businesses. A 2017 study of firms in Sweden found that smaller businesses that were exempt from a 2001 employment protection law were 2 to 7 percent more productive than firms that were subject to laws similar to Puerto Rico's Law 80.<sup>31</sup>

Di Tella and MacCulloch surveyed entrepreneurs from twenty-one OECD (Organization for Economic Cooperation and Development) countries, asking them to assess the impact of their countries' laws on their hiring and dismissal practices. This study found evidence that the increased flexibility in the rules applicable to employer authority in the hiring and firing process increases *both* employment levels and labor participation rates, even in periods of recession. The study also found evidence that greater flexibility in the hiring and firing stages leads to lower unemployment rates. Providing a conservative estimate, they concluded that if France were to make its labor employment rules as flexible as those in the U.S., its employment rate would increase 1.6 percentage points, or 14% of the employment gap between the two countries.<sup>32</sup>

Other studies sponsored by the OECD have documented that excessive employment protections increase the rate and duration of unemployment and reduce rates of employment.<sup>33</sup> A second study examining 73 developed and developing countries found that protectionist labor regulations increase unemployment.<sup>34</sup> For example, the study suggests that if Italy (a country with extensive labor protectionist regulations) adopted the labor regulations of the U.S., the unemployment rate

Page 18 of 35

in Italy for the population in general would be reduced by 2.3% (and for young people, unemployment would be reduced by 5.6%). One of the reasons for this is that the rigidity of labor regulations negatively impacts domestic and foreign investments.

When Colombia reduced the cost of dismissing workers, unemployment fell, and the size of the informal labor force declined.<sup>35</sup> In a 2004 book on labor laws in Latin America and the Caribbean, Nobel Prize-winning economist James Heckman concluded that

“mandated benefits reduce employment and... job security regulations have a substantial impact on the distribution of employment and on turnover rates. The most adverse impact of regulation is on youth, marginal workers, and unskilled workers. Insiders and entrenched workers gain from regulation but outsiders suffer. As a consequence, job security regulations promote inequality among demographic groups.”<sup>36</sup>

This review of the literature should make clear the costs that are imposed on residents of Puerto Rico by policies that, while well-intentioned, increase the costs and risks of hiring employees. The repeal of Law No. 80 will facilitate the entry of young or unemployed workers into active employment.

Properly implemented, a more open labor market can help attract new investors to Puerto Rico. Substantial research shows that multinational companies are increasingly taking labor laws into consideration when making business location decisions. Jurisdictions with lesser risks and costs are more attractive for job creating investors.<sup>37</sup>

**b. The basis for the labor reform’s projected impact is supported by case studies across a wide range of countries where similar reforms were successful in increasing growth.**

Labor market reforms taken in individual European countries have made the labor market more flexible, increased labor supply, and led to a long-run additional 3.5% annual growth in peripheral European countries, where economies are most similar to Puerto Rico. When excluding reforms not as relevant to Puerto Rican labor reform identified in the New Fiscal Plan, such as unemployment insurance and pension reform, the case studies still support an estimation of an additional 1.4% growth over the long-run, and key to the issue at hand is the finding that just the elimination of employment protection itself accounted for 0.5% of permanent growth.<sup>38</sup>

– For the EITC, in a study by the Central Bank of Malta (a country that is small and tied intimately to a very large neighbor in the EU, very much like the case of Puerto Rico), the EITC and welfare reform were linked to overall growth through increasing female labor force participation rates, which were found to result in an increase in growth of 0.8% per year.

– Spain’s 2012 labor reform law, enacted in response to the recession, loosened many of Spain’s restrictive employment protection policies, pushing it down below the OECD labor stringency average and potentially creating a 0.25% annual increase in business sector productivity, or 0.15% annual increase in GDP.<sup>39</sup>

– Estonia implemented reforms to ease hiring and dismissal procedures, as well as to allow the use of fixed-term contracts in all cases. These contracts are very similar to at-will employment. The reforms also cut severance payments. Estonia’s unemployment rate fell 5.5 percentage points from 19.8% to 13.3% between 2008 and 2011.<sup>40</sup>

– Influenced by the financial crisis, total employment in Portugal fell by 15% over 2008 to 2013. In response, Portugal made a series of structural reforms to reduce excessive employment protections. These included reducing severance pay and relaxing the definition of fair dismissal, but there is still more to be done to bring Portugal closer to the OECD average. The OECD estimates that new labor reforms have already begun contributing to increased labor productivity,

Page 20 of 35

and could lead to a 0.5% increase in GDP by 2020.<sup>41</sup> Portuguese employment rates have also been growing stronger than forecasted.

– Comprehensive labor market reforms in Italy 2014 are expected to result in 0.6% GDP growth within 5 years, and 1.2% growth within 10 years. Reforms to trigger this growth include loosening employment protections, expanding active labor market policies, and increasing female workforce participation. These reforms will create an estimated 150,000 jobs in 5 years and 270,000 jobs in 10 years.<sup>42</sup>

– Slovenia introduced reforms in 2013 to make the labor market more flexible and to increase employment opportunities for younger workers. The OECD expects these reforms to boost Slovenian GDP by 0.2% in the first five years and by 0.3% in the first 10 years.<sup>43</sup>

– In Peru, a 10% increase in costs associated with employee dismissal reduced long-run employment rates by 11% between 1987 and 1990. The use of severance payments was also found to have a negative effect on employment levels.<sup>44</sup>

– The *Pacta por Mexico* introduced labor reforms alongside education, healthcare, and judiciary reforms. The OECD estimates that employment protection initiatives specifically will have contributed to about an 0.05% increase in GDP over 5 years.<sup>45</sup>

– Colombia reduced its employer payroll taxes, effectively making workers less expensive, and saw a decrease in the size of its informal labor market.<sup>46</sup>

– A 2017 survey of prominent economists regarding France’s labor laws – which are similar to those in Puerto Rico in mandating generous paid leave and strong employment protections –

found two-thirds believe that reducing these labor laws would improve the country's economy and reduce the unemployment rate. Less than 5% of the economists surveyed disagreed.<sup>47</sup>

– In India, a 2004 study found that states with strict labor laws experienced lower manufacturing growth by around 23% to 24%; while states with more flexible legislation experienced increases by a similar amount.<sup>48</sup>

The reforms aimed at flexible labor regulations are expected to be successful in Puerto Rico due to key characteristics of the Island's economy that overlap with selected case studies. While there are numerous case studies that clearly demonstrate the positive effects of labor reform, the specific case studies used to support the transformational nature of these reforms in Puerto Rico were conducted in countries with key similarities to Puerto Rico.

- **Currency union:** Case studies utilized to reach impact estimates for labor reform were all derived from countries within currency unions. As a result, none had the ability to enact monetary policy that would bolster the impact of labor reforms, and they were still quite effective. Similarly, Puerto Rico's monetary policies are driven by the U.S. Federal Reserve.
- **Large informal economy:** In the periphery of the European Union, multiple countries such as Greece and Spain have informal economies that represent 20 - 30% of GDP. Thus, in both cases, moving firms and workers into the formal economy contributes toward the positive economic and fiscal impact of labor reforms. Reducing the size of informal economy also has a critical impact of increasing upward mobility and skill acquisition for low-wage workers in Puerto Rico.
- **Ease of capital flow:** Puerto Rico's unique status as a U.S. territory significantly eases the flow of capital and business from the mainland United States. As a result, a more flexible labor market offers the opportunity for Puerto Rico to attract firms from the mainland to open or expand operations on the Island. For example, France, which can attract investments from across Europe through its membership in the EU, saw a major spike in interest from business executives looking to invest in the country after President Macron successfully implemented labor reform. 60% of executives saw the country as an attractive place for companies in 2017, nearly triple the 2014 figure of 23%.
- **Large short-term stimulus:** Over the next 10 years, the Fiscal Plan projects over \$60 billion of disaster related funding to rebuild Puerto Rico. This funding is expected to produce an increase in demand, despite the long-term recession of Puerto Rico's economy. As a result, Puerto Rico will find itself at an opportune time to carry out such reforms (opposed to countries that enacted labor reforms during major economic downturns, such as Greece and Spain). The reforms should have a synergistic impact to the additional stimulus and provide a sound basis for future investors to come to Puerto Rico to establish

<sup>48</sup> Besley, Timothy and Burgess, Robin, "Can Labor Regulation Hinder Economic Performance? Evidence from India," *Quarterly Journal of Economics*, Volume 119, Issue 1, 1 February 2004, Pages 91–134.

new businesses and hire workers. Change – even if necessary – can be disruptive, which is why it is best done during a time when the economy is expected to improve.

**c. Law No. 80 is part of the problem; not the only problem.**

**The repeal of Law No. 80 will not by itself cure the economic woes of the island. While significant, it is only one of the components of a Labor Reform Package that Puerto Rico needs to address. The change in the regime that regulates discharge decisions is part of a strategy to attract job creating investments to the Island. Moreover, the economic literature is clear--rules like Law No. 80 skew investments to capital-intensive operations and reduce in relative terms the demand for labor, which means Puerto Rico will continue its pattern of fewer employment opportunities.**

Puerto Rico needs to get the economy moving today. This will require hiring people at the lower end of the wage spectrum and getting them out of the informal economy and into formal jobs. This requires the effective implementation of the entire package of labor reform. Adopting the “at will” employment regime that has supported the substantially more successful economies of mainland states, is a necessary foundation to moving forward.

Much of the questioning in the public discourse has been around how the structural reforms, in particular labor, will positively impact Puerto Rico’s residents. The reality is that a single reform, in isolation from the rest, is not likely to impact growth substantially. Rather, it is the whole program and package of structural reforms that truly change the competitiveness of an economy. Puerto Rico, now more than ever, needs to focus on transforming the economy into one that is competitive.

**By putting the Puerto Rico labor market on a competitive footing with other U.S. jurisdictions, this will make the investment environment in Puerto Rico more competitive with those same U.S. jurisdictions. It is from the increased investment that the demand for labor will find its biggest boost and begin a virtuous cycle of investment, employment, growth and further investment. By focusing on changing Puerto Rico’s labor environment, new investors will be attracted to Puerto Rico given the confidence in a strong labor market that has flexible rules. By getting firms to invest, economic growth will be enabled.**

**d. Many employment protection laws will continue to apply**

Adopting the “at-will” employment regime will not diminish labor standards for workers in Puerto Rico. Moreover, they will continue to be protected by a very broad scope of antidiscrimination laws. Remedies under these laws are typically greater than the relief under Law No. 80. Excluding all applicable federal laws, Puerto Rico law will continue to prohibit the discharge of an employee for the following reasons:

- Because of age, race, color, sex (gender), sexual orientation, gender identity, social origin or condition, national origin, political or religious beliefs or affiliation, disability, marriage to an employee of the employer, being a victim or being perceived as a victim of domestic violence, sexual aggression or stalking,

present or prior military service, or veteran status.<sup>49</sup>

- Retaliation for having opposed sexual harassment in the workplace; having filed a complaint, testified or collaborated or participated in any manner in an investigation, proceeding or hearing in connection with a sexual harassment complaint.<sup>50</sup>
- For providing or intending to provide verbal or written testimony or information to an administrative, judicial, or legislative body in Puerto Rico, or in accordance with the employer's established internal procedures or before an employer's representative with authority, provided the expressions are nondefamatory and do not disclose legally protected confidential or privileged information.<sup>51</sup>
- For having (a) disclosed his/her salary to other employees or asked other employees about their compensation; (b) objected to any practice prohibited by Puerto Rico's Equal Pay Act (PREPA); (c) submitted a grievance or complaint regarding PREPA rights in any forum, or (d) offered or tried to offer, verbally or in writing, any testimony or information in an investigatory procedure against the employer regarding PREPA violations.<sup>52</sup>
- Dismissal, without just cause, of a pregnant employee.<sup>53</sup>
- For refusing to enter an alternate weekly work schedule agreement (which includes compressed workweeks) or for requesting the modification of the schedule, number of hours, or place of work as authorized under Puerto Rico's

employee upon conclusion of the military duty.<sup>61</sup>

- Dismissing or refusing to reinstate an athlete or trainer certified by the Puerto Rico Olympic Committee as athletes or trainers participating in certain sports events that require leaves of absence.<sup>62</sup>
- For filing a complaint against the employer under the Puerto Rico Occupational Safety and Health Act (PROSHA), having caused an investigation, testifying or intending to testify regarding matters covered under the act or failing to reinstate the employee after participating in a required medical examination.<sup>63</sup>
- Dismissing an employee, without just cause, while legally protected leaves for work-related and non-work-related disabilities under the workers compensation and non-occupational disability programs, as well as refusing to reinstate the employee after being released from treatment in accordance with the provisions of such laws.<sup>64</sup>

#### **e. Welfare Structure Reforms**

To implement the labor reform package, address labor market challenges and encourage residents to participate in the formal labor market, the Government must launch an Earned Income Tax Credit (EITC) program by January of 2019. The Government also must institute a work requirement for the Nutrition Assistance Program (PAN).

---

<sup>61</sup> Art.4(f)(1) and Art. 9, Law No. 203 of December 14, 2007, as amended, P.R. LAWS ANN. tit. 29, §§737(f)(1) and 742 (2017) (triple damages and reinstatement); Art. 233, Law No. 62 of June 23, 1969, as amended, P.R. LAWS ANN. tit. 25, §2085 (2017) (back pay and reinstatement).

<sup>62</sup> Art. 5, Law No. 24 of January 5, 2002, P.R. LAWS ANN. tit. 15, §1111 (2017) (double damages and reinstatement).

<sup>63</sup> Art. 10(d) and Art. 29, Law No. 16 of August 5, 1975, as amended, P.R. LAWS ANN. tit. 29, §§361i(d) and 361aa (2017) (back pay, reinstatement, and other injunctive relief).

<sup>64</sup> Art. 5-A, Law No. 45 of April 18, 1935, as amended, P.R. LAWS ANN. tit. 11, §7 (2017) (damages and reinstatement); Art. 3(q), Law No. 139 of June 26, 1968, as amended, P.R. LAWS ANN. tit. 11, §203(q) (2017) (damages and reinstatement). A worker who regularly drives a motor vehicle to perform his job duties is exempt from Law No. 139, but receives similar reinstatement protections for disability absences under Article 16 of Law No. 428 of May 15, 1950, P.R. LAWS ANN. tit. 29, §693a (2017) (damages and reinstatement). If a person is unable to work due to an accident suffered while legally driving a motor vehicle on the public highways, similar job reinstatement protections are also available in accordance with another statute. Art. 4, Law No. 138 of June 26, 1968, as amended, P.R. LAWS ANN. tit. 9, §2054 (2017) (damages and reinstatement).

## **Earned Income Tax Credit (EITC)**

The EITC is a benefit for working people with low-to-moderate income. To qualify, people must meet certain requirements and file a tax return, even if they do not owe any tax. The EITC reduces the amount of taxes owed and may result in a cash refund if the benefit is higher than owed taxes.

Since welfare reform in 1996, the EITC has become the cornerstone of anti-poverty policy in the U.S. It has refocused the U.S. safety net on working families, dramatically increasing employment among single women with children and removing more children from poverty than any other program. In the U.S., this translates to approximately 6.5 million people (half of whom are children) lifted out of poverty. Further, the EITC improves employment rates (a \$1,000 increase in EITC benefit has been tied to a 7.3 percent increase in employment)<sup>65</sup> and provides increased opportunities for individuals to invest in their own futures with education, training, childcare, or other costs that improve longer-term outlook. It has proven a powerful incentive to transition into the formal labor force and file taxes.

From 2006 to 2014, Puerto Rico had a Worker's Tax Credit, which was later discontinued due to its ineffective application and as a cost-saving measure. This prior Work Credit applied to 45% of all tax filers at a cost of \$152 million in its last year of implementation. It was smaller than Federal EITC programs (\$150-450 versus ~\$2,000 average credit) and did not eliminate high implicit tax rates on low-income employees or do enough to incentivize formal employment.<sup>66</sup>

In Puerto Rico, implementation of the new EITC should be similar to the Federal EITC but adjusted to the relative wages of the Island. Eligible recipients should receive credits according to their marital, family, and earned income. As earnings increase, the benefit should increase up to a specified cap; at the cap, it would plateau and eventually decrease at the phase-out income level until it reaches \$0 (**Exhibit 5**), resulting in an average benefit of \$525.30 per individual per year. This structure diminishes the "benefits cliff" that many face as their earned income increases, rewarding citizens who participate in the formal economy.

<sup>66</sup> New York Federal Reserve Bank, 2014

**Exhibit 5: EITC Benefit Formula**

EITC Benefit Formula, \$

- Benefits begin with the first dollar of reported income. As income increases, **benefits also increase at the phase-in rate** (different depending on household size), **up to the maximum credit**
- When income **reaches the phase-in cap, the benefit increase ceases**. Benefits remain constant at income levels that fall between the phase-in cap and phase-out start
- When income **reaches the phase-out start, benefits begin decreasing at the phase-in rate** for each additional dollar earned, **until income reaches the income cap** (at which point benefits are \$0)

Number of Children	Phase-in rate, %	Phase-in cap, \$	Phase-out start, \$	Individual/ Single income cap, \$	Married income cap, \$	Maximum Credit, \$
0	5.00%	6,000	18,000	20,500	21,750	<b>300</b>
1	7.50%	12,000	13,000	20,500	24,250	<b>900</b>
2	10.00%	15,000	16,000	28,500	34,750	<b>1,500</b>
3 or more	12.50%	16,000	17,000	33,500	42,000	<b>2,000</b>

For example, a single mother with two children working at minimum wage for 35 hours per week earns approximately \$12,180 annually. With EITC, she can qualify for up to \$1,500 in additional take-home pay per year, effectively raising the minimum wage by more than 12%.

The EITC program would cost approximately \$200 million per year, but the program will raise formal labor force participation significantly, providing a positive return on the investment. The EITC must be implemented no later than FY2019.

**PAN Work Requirement**

While PAN, Puerto Rico’s largest welfare program, is similar to the mainland SNAP, it is funded and administered separately and unlike the mainland program PAN does not include a work requirement. As part of the labor reform package that the Oversight Board projects will create substantial growth over the next 30 years, the New Fiscal Plan requires that the Government institute work requirements to qualify for PAN benefits.

In FY2019, able-bodied participants aged 18-59 will be subject to a work requirement (children, even if their parents do not work, will continue to receive the benefit). Like mainland SNAP, in full implementation this work requirement must become effective after the individual has collected PAN benefits for three months. General exceptions would include those under age 18 or over the age of 60, parents with dependents under age 18, as well as those who are medically certified as physically or mentally unfit for employment. Paid work, voluntary work, training and education, and job searching (under the time limit) must qualify as work.

Any program savings derived from the PAN work requirement must be redistributed to working beneficiaries, effectively increasing take-home pay for workers. The increased worker benefit shall

**Memorandum: Labor Reform as a Catalyst for Growth**

Page 28 of 35

take place through an expansion of the Earned Income Disregard, which will increase the amount of earned income eligible recipients can exclude in calculating the amount of benefits they can claim. For example, a family of four currently receiving PAN will lose the benefit after exceeding a maximum annual income of \$5,904. By creating a sliding scale after this amount or allowing families to exclude a certain amount of earned income from this calculation, Puerto Rico can ensure no one is disadvantaged by seeking work in the formal economy and that no families lose benefits prematurely.

The increase in PAN benefits for workers combined with the EITC would improve conditions for low-income workers in the formal economy and reduce poverty.

The proposed PAN work requirements must be included in the new PAN annual plan submitted July 1, 2018 to Food and Nutritional Services. It will be phased in over two years. Beginning in FY2019, beneficiaries will be subject to the work requirement after 6 months of benefits. By FY2020, the full requirements will take effect, subjecting beneficiaries to the work requirement after 3 months of benefit collection.

### **Workforce Development Programs**

Labor and welfare reforms should increase supply and demand for jobs; to fully close the gap and implement the labor reform package, however, the Government must launch specific efforts to ensure that its future workforce is prepared with critical skills.

### **Workforce Innovation and Opportunity Act (WIOA)**

First, the Government must update the WIOA State Plan to focus its programs and incentives on high-priority sectors and capabilities. WIOA is the primary way in which the Federal Government invests in adult education and workforce development, and it is designed to help jobseekers access employment, education, and support services to succeed in the labor market, and to match employers with the skilled workers they need.

The Government must broaden the list of core industries that qualify under WIOA and focus on high impact economic sectors to provide a skilled workforce that meets the needs of employers in each specific region. It needs to integrate this WIOA program with the broader promotional efforts of the Department of Economic Development and Commerce (DDEC). For example, a MOE Agreement with the Puerto Rico Department of Labor and Human Resources must establish an apprenticeship program aiming to impact innovative industries and post-Maria labor market needs.

### **Youth Development Initiatives**

In addition to WIOA, the Government should help develop critical skills in the workforce through multiple proposed initiatives, including:

**Youth development:** Investment in STEM through targeted teacher professional development and related programs; apprenticeship programs through partnership with universities and local businesses; opportunities for work-based learning and business programs; occupational opportunities and certification programs (funded through reinvestment in additional surplus achieved through comprehensive labor reform).

**Higher education:** Curriculum development grants and scholarships for UPR students focused on high-impact sectors, e.g., the IT industry and Computer Science.

**Current labor market:** Apprenticeship Programs through collaboration with the private sector; training & certification programs focused on the areas of reconstruction efforts; creation of a job council to coordinate development and employment opportunities for youth and the unemployed.

By pursuing aggressive reforms to incentivize job creation and formal labor market participation, and to improve the overall quality of human capital in Puerto Rico, the Government will fundamentally transform the Island's labor market for the better.

## **VI. Comprehensive Set of Structural Reforms**

As previously mentioned, a single reform, in isolation from the rest, is not likely to impact growth substantially. Rather, it is the whole program and package of structural reforms that truly change the competitiveness of an economy. Puerto Rico, now more than ever, needs to focus on transforming the economy into one that is competitive. A sustainable fiscal and economic turnaround depends entirely on comprehensive structural reforms to the economy of Puerto Rico. Only such reforms can drive growth in the economy, reversing the negative trend growth over the last 10 years and enabling the Island to become a vibrant and productive economy going forward. To reverse the negative economic trends, reforms should be undertaken in the following areas:

**Human capital and workforce reforms** will improve workforce participation, well-being and self-sufficiency of welfare recipients, and preparedness of adults and youth for a long and fulfilling career, resulting in a cumulative GNP impact of 0.80% by FY2023. The impact is enhanced in the long-term as K-12 education reforms begin adding an additional 0.01% GNP impact per year, resulting in an additional 0.16% uptick by FY2048.

**Ease of doing business reforms** will improve conditions for economic activity and job creation, employment opportunities, and business vitality, resulting in cumulative GNP impact of 0.65% by FY2023.

**Power sector reforms** will improve availability and affordability of energy for families and businesses, resulting in 0.30% cumulative GNP impact by FY2023.

**Infrastructure reform and capital investment** will improve the flow of goods, services, and people across the Island. It has not been scored to provide a specific GNP uptick, yet is undoubtedly a consequential uptick in the Island's long-term development.

The timing and impact of structural reforms are based on work done by the IMF on similar reforms implemented in Europe, utilities reform in Latin America, and broadly accepted metrics for measuring improvement in the World Bank's Ease of Doing Business Rankings.

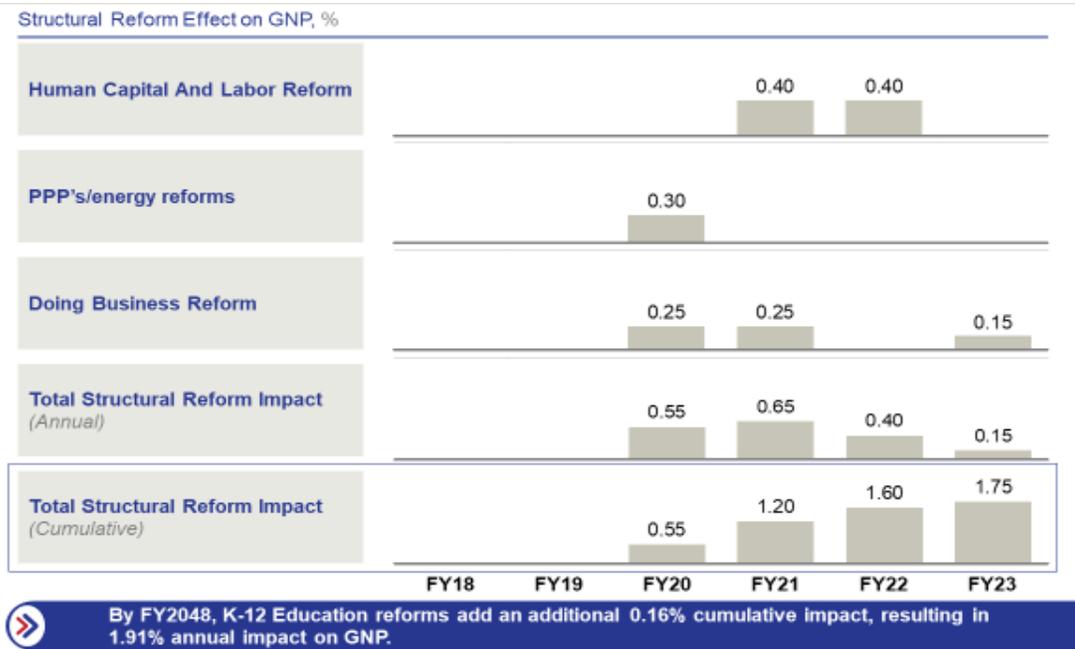

Structural reform benchmarks broadly come from nations or jurisdictions without monetary policy options, like Puerto Rico. Examples used include Eurozone nations, U.S. states, or countries that had currencies pegged to the United States Dollar – and therefore lack monetary flexibility as does Puerto Rico. If implemented effectively, labor, energy, and doing business, reforms are projected

**Memorandum: Labor Reform as a Catalyst for Growth**

to increase GNP by 1.75% by FY2023. K-12 education reforms add an additional 0.01% annual impact beginning in FY2033, resulting in total GNP increase of 1.91% by FY2048 (**Exhibit 6**).

**Exhibit 6: Macroeconomic Impact of Structural Reforms**

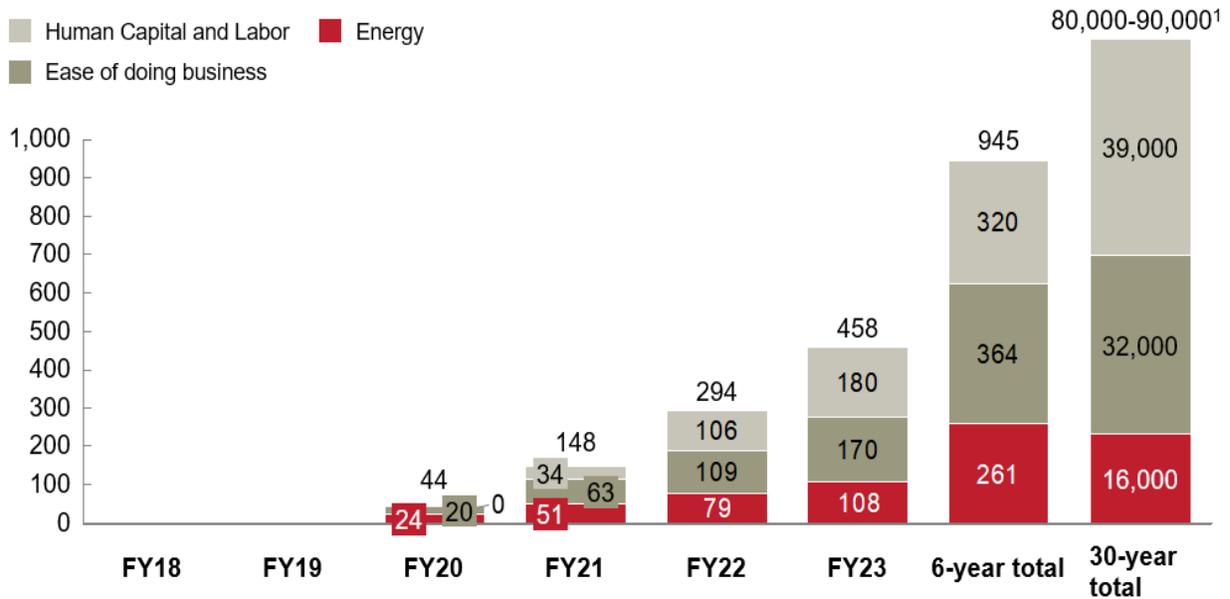

As shown below (**Exhibit 7**), these reforms equal approximately \$80-90 billion in increased Commonwealth revenues over 30 years. The reforms are crucial to placing Puerto Rico on a path to long-term structural sustainability.

**Exhibit 7: Impact of Structural Reforms Over 30 Years**

Impact of structural reforms, \$M

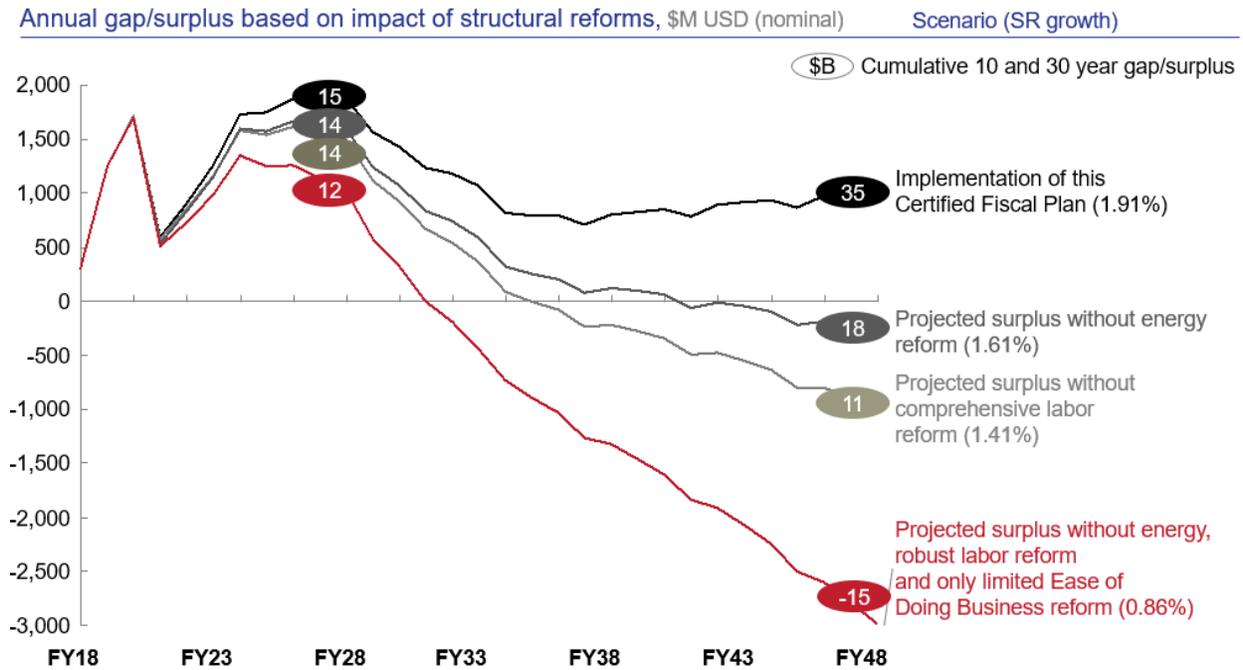

<sup>1</sup> Structural reforms in the 30-year are estimated due to macroeconomic compounding and long-term projection uncertainty

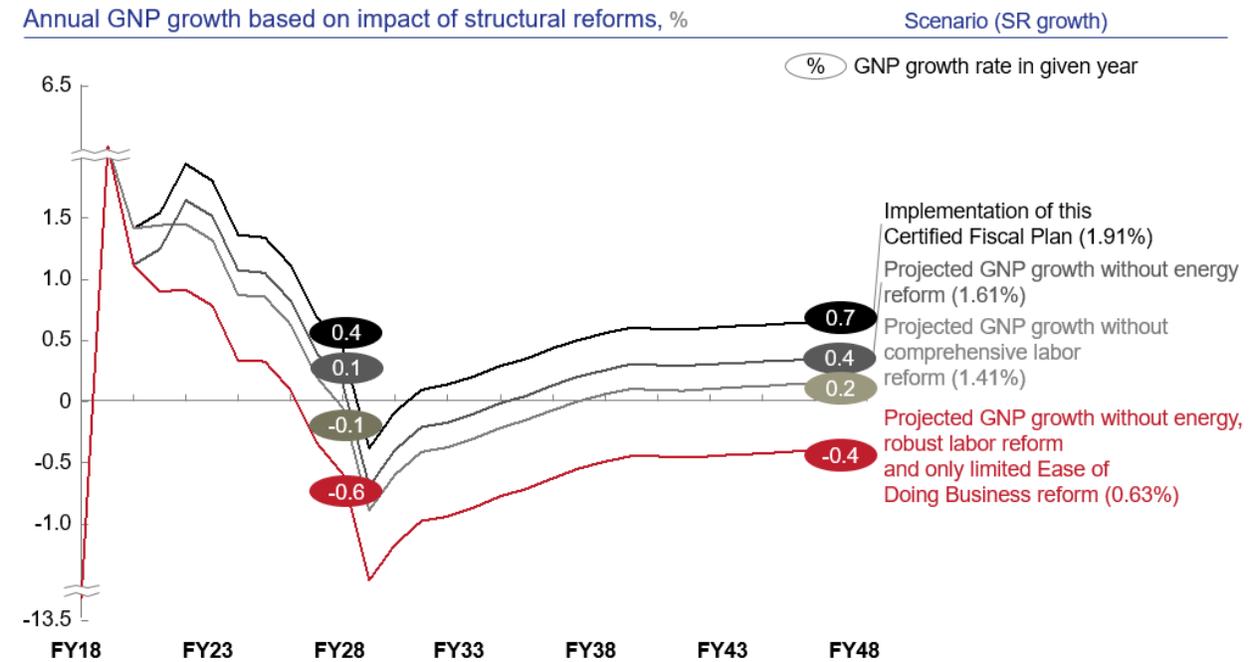

The entire package of structural reforms presents a transformational path for Puerto Rico, in which the long-term trend of decline turns into growth. However, without such structural reforms, there would be deficits by FY2032 (**Exhibit 8**). Similarly, this path ensures that the 1.91% impact from structural reforms by FY2023 will allow Puerto Rico to grow consistently thereafter; the path shown without the implementation of the reforms does not allow Puerto Rico to grow in the future (**Exhibit 9**). It is the full implementation of these reforms – human capital and labor, energy, and ease of doing business– that will allow the Island to achieve a sustainable economic future.

### Exhibit 8: Annual Gap/Surplus Pre-Debt Service Based on Impact of Structural Reforms

### Exhibit 9: Puerto Rico's GNP Outlook

## **VII. CONCLUSION**

As stated in the New Fiscal Plan, Puerto Rico will receive over \$60 billion of disaster related funding to rebuild the Island within the next 10 years. The federal funding will provide a cushion of time within which Puerto Rico must continue the hard work of making the necessary structural changes, reforms, and adjustments that will allow it to reverse the over a decade-long negative growth trend of the Puerto Rican economy, such that we can achieve fiscal balance, restructure the debt to sustainable levels, and return to capital markets.

Collectively, the labor reforms are transformational and will create opportunity for the future work force of Puerto Rico. The focus is to make Puerto Rico more competitive, and in turn create jobs, instill confidence, and change Puerto Rico's negative economic outlook trend to a positive one. The options are clear: full implementation of reforms present a path forward for Puerto Rico's GNP growth – one that will reawaken the economic prosperity Puerto Ricans have long been deprived of.

The New Fiscal Plan starts from the premise that the citizens of Puerto Rico deserve better – more opportunity for work, and an environment that is conducive to entrepreneurship and business creation. The reforms combine proven incentives for those who work, in the form of an Earned Income Tax Credit, with liberalization of the labor market rules that have made Puerto Rico out-of-step with U.S. states. Increasing labor force participation also levels the playing field by bringing workers from the informal sector into the formal economy, contributing to the Commonwealth's tax base needed to fund government services.

The implementation of the full range of structural reforms proposed in the New Fiscal Plan will prove to be transformational for Puerto Rico. The focus should be to implement this portfolio of reforms in its entirety to be able to deliver the maximum positive impact for the people – create more jobs and opportunity, instill confidence, strengthen the island's competitiveness and return the economy to growth mode, as well as to allow for a reasonable Plan of Adjustment that helps put an end to Title III court proceedings.

# A Race to the Bottom? Employment Protection and Foreign Direct Investment

William W. Olney<sup>1</sup>

First Draft: November 2010

Revised: April 2011

## Abstract

A common critique of globalization is that it leads to a race to the bottom. This hypothesis assumes that multinationals invest in countries with lower regulatory standards and that countries competitively undercut each other's standards in response. This paper examines both assumptions and finds evidence of the first but no support for the second. Specifically, a reduction in employment protection rules leads to an increase in foreign direct investment (FDI). Not surprisingly, changes in employment protection legislation have a stronger impact on the relatively mobile types of FDI. However, there is no evidence that countries are competitively undercutting each other's labor market standards, despite the fact that doing so would attract FDI.

*Keywords:* foreign direct investment; employment protection; race to the bottom

*JEL Codes:* F16; F23

---

<sup>1</sup>Department of Economics, Williams College, Williamstown, MA 01267 (email: [william.olney@williams.edu](mailto:william.olney@williams.edu)).

# 1 Introduction

The race to the bottom hypothesis hinges on two important assumptions. First, it is assumed that multinational enterprises (MNE) choose to invest in countries with less restrictive standards. Second, it is assumed that foreign countries competitively undercut each other's standards in order to attract FDI. While a common critique of globalization is that it can lead to a race to the bottom, there is relatively little evidence supporting either of these key assumptions. This paper tests these predictions by examining the impact of employment protection legislation on FDI and by examining the impact of labor market standards in other countries on the employment protection legislation in the foreign host country.

The mobility of capital, and in particular FDI, has increased substantially in the last twenty five years. U.S. direct investment abroad as a share of gross domestic product has increased from 6% in 1982 to 25% in 2009. Advances in transportation and communication have allowed different production activities to be relocated abroad. However, labor market regulations, such as hiring and firing restrictions, will increase the costs of doing business in a particular foreign country. As employment protection rules become stricter in one country, multinationals will shift production activities to another relatively less costly location. Thus, according to the first assumption of the race to the bottom hypothesis, labor market restrictions will reduce FDI. Furthermore, the response of multinationals to employment restrictions likely depends on the type of FDI. Relatively more mobile types of FDI will have a greater ability to respond to changes in labor market restrictions than FDI that is tied to a specific location. For instance, vertical FDI, which is motivated by the desire to take advantage of low foreign factor prices, can be relocated to less expensive locations relatively easily. However, horizontal FDI, which is motivated by the desire to access a foreign market, needs to be near the foreign consumers.

The second key assumption of the race to the bottom hypothesis is that countries lower their labor standards in order to undercut their competitors and attract FDI. As the average labor standards in other foreign countries decreases, the foreign host country will lower their labor standards in response. Thus, the average employment restrictions in other

foreign countries should have a positive impact on the employment protection rules in the host country. While the intuition of the race to the bottom hypothesis is relatively straightforward, there is little empirical evidence to support either assumption.

This paper examines these predictions using data on FDI by U.S. multinationals and data on employment restrictions in twenty six foreign countries which collectively account for over three quarters of U.S. outward FDI. Focusing on U.S. FDI is appealing because it fixes parent country characteristics that may influence FDI. In addition, using detailed data from the Bureau of Economic Analysis (BEA) on foreign affiliate sales of U.S. multinationals allows horizontal, export-platform, and vertical FDI to be separately identified. The measure of employment protection used in this analysis is a composite index of hiring and firing costs obtained from the Organisation for Economic Co-operation and Development (OECD). This provides a consistent and objective measure of differences in employment protection legislation across countries and over time. Spanning twenty six countries and twenty three years, the data set provides the scale and scope necessary to examine both assumptions of the race to the bottom hypothesis.

To test the first assumption, the empirical analysis controls for time and country fixed effects and estimates the relationship between employment protection and FDI using ordinary least squares (OLS), dynamic panel generalized methods of moments (GMM), and instrumental variables (IV). The results in all specifications indicate that employment protection has a significant, negative impact on the foreign affiliate sales of U.S. multinationals. This is consistent with the prediction that labor market restrictions will increase the costs of production in the host country and thus reduce U.S. FDI to that foreign country.

Even more compelling is that the impact of employment protection varies across different types of FDI in the manner predicted. There is relatively little impact of employment restrictions on affiliate sales to the local market (horizontal FDI) but a more significant impact of employment restrictions on affiliate sales to other foreign countries (export-platform FDI). Finally, there is a large, negative, and significant impact of employment restrictions on affiliates sales back the U.S. (vertical FDI). These contrasting results, provide compelling evidence that labor market restrictions have the largest effect on the relatively more mobile types of FDI. Thus, there is evidence that FDI responds to labor market restrictions and

that this response is strongest among the most footloose types of FDI. This verifies the first assumption of the race to the bottom hypothesis and provides a motivation for countries to lower their employment protection rules.

The second key assumption of the race to the bottom hypothesis is that countries competitively undercut each other's labor market standards in order to attract FDI. To test this proposition, this paper examines whether host country employment protection legislation depends on changes in labor market standards in other foreign countries. Competitor's labor market standards are quantified as the average of employment protection in other foreign countries, which is calculated as an unweighted average, a weighted average based on distance, or a weighted average based on vertical and export-platform FDI. OLS, GMM, and IV results indicate that host country employment protection legislation does not depend on the employment restrictions in other foreign countries regardless of which weighting system is used. There is no evidence that countries are competitively undercutting each other's labor market restrictions, despite the fact that doing so would attract foreign direct investment. Thus, this paper finds evidence supporting the first assumption of the race to the bottom hypothesis but no evidence of the second assumption.

Additional results examine the relationship between employment protection and vertical FDI in greater detail. Specifically, findings indicate that employment protection rules decrease sales to U.S. parents and to a lesser extent sales to unaffiliated U.S. parties. In addition, sales of goods, rather than sales of services, are more responsive to employment restrictions. There is also evidence that both firing and hiring restriction have an important affect on vertical FDI, with the former having a larger negative impact than the latter. Finally, an alternate maximum likelihood estimation strategy is used to examine the robustness of the results that test the second assumption of the race to the bottom.

Multinationals play a crucial role in the increasingly integrated global economy. For instance, forty percent of all U.S. trade occurs within the boundaries of the firm (U.S. Census 2010). Understanding how multinationals decide where to locate production facilities is crucial in explaining trade flows and understanding the implications of globalization more generally. The determinants of FDI have been studied extensively (Carr et al. 2001, Markusen and Maskus 2002, Blonigen et al. 2007). These studies have convincingly shown

that foreign country characteristics such as GDP, skill level, trade costs, investment costs, and distance are important determinants of FDI. While the idea that multinationals are attracted to foreign countries with less restrictive labor standards is intuitive and is gaining traction in the popular press, relatively little is actually known about whether this is an important determinant of FDI. The results in this paper provide clear evidence that labor market restrictions have a significant effect on FDI.

Research on labor market restrictions typically focuses on the implications for employment (Lazear 1990, Acemoglu and Angrist 2001, Di Tella and MacCulloch 2005, Boeri and Jimeno 2005) and for output (Besley and Burgess 2004). An important contribution of many of these studies, relative to earlier work, is to look at within country variation using panel data rather than simply making cross country comparisons. In this paper, I also control for unobserved country characteristics but look at the global ramifications of employment protection. Given the increasingly integrated world economy and the growing importance of multinationals, it is also important to consider how employment restrictions will affect FDI.

The few studies that examine the link between employment protection and FDI generate mixed results. For instance, Rodrik (1996) and OECD (2000) find evidence that a decrease in labor standards reduces FDI, contrary to the predictions of the race to the bottom hypothesis. Bhagwati (2007) also argues that there is no evidence that multinationals are attracted to countries with lower labor standards. However, other studies find that less restrictive employment protection rules increase FDI (Gorg 2005, Dewit et al. 2009, Javorcik and Spatareanu 2005, Benassy-Quere et al. 2007). While similar in spirit, these papers typically rely on more ad hoc and subjective measures of hiring and firing costs than the employment protection measured used in this analysis. Furthermore, none of these papers examine the impact of labor market restrictions on different types of FDI. An important contribution of this paper is the finding that the impact of labor market restrictions on FDI depends crucially on the type of FDI.

While Azemar and Desbordes (2010) also look at different types of FDI, their measure of employment protection has no annual variation. In contrast, this paper exploits changes in labor market restrictions within a country over time. The ability to control for country

and year fixed effects and the ability to identify a causal impact of employment protection on FDI using the GMM and IV estimation strategies represent important contributions of this paper.

Tests of the race to the bottom hypothesis tend to focus on whether multinationals invest in countries with lower regulatory standards. As mentioned, the evidence regarding this first assumption is far from conclusive. However, tests of the second assumption of the race to the bottom hypothesis are even rarer. To the best of my knowledge, this is the only paper to examine whether countries competitively undercut one another's labor standards. Thus, this is the first comprehensive empirical test of the race to the bottom hypothesis.

The remainder of the paper proceeds as follows. Section 2 discusses the assumptions of the race to the bottom hypothesis. The estimation strategy is described in Section 3, while the data and descriptive statistics are presented in Section 4. The results are discussed in Section 5 and extensions are presented in Section 6. Finally, Section 7 concludes.

## **2 Race to the Bottom**

### **2.1 Assumption 1**

The first assumption of the race to the bottom hypothesis is that multinationals choose where to invest based in part on the employment restrictions within the foreign country. Fundamentally, stricter labor restrictions will impose additional costs on MNE and make investing in that particular country less appealing. In addition, FDI that is relatively more mobile, in the sense that it can be equally effective in a variety of different countries, should be more responsive to labor restrictions. As the costs associated with FDI increase due to employment protection legislation, the multinational will simply shift FDI to other countries. Thus, the responsiveness of FDI to employment protection legislation will depend crucially on the type of FDI.

Horizontal FDI occurs when a multinational invests in a country in order to access that foreign market and avoid transport costs associated with exporting the good from home (Markusen 1984). The MNE shifts the entire production process to the foreign country and then sells the output to local consumers. Thus, the decision to pursue horizontal FDI de-

depends on a "proximity-concentration trade-off" between the home and foreign country in which the benefits associated with being close to the foreign market need to be weighed against the costs associated with setting up production activities abroad (Brainard 1997). With horizontal FDI, the choice set facing the multinational is producing at home or producing in the foreign country whose market they want to access. Since other foreign countries are not a viable destination for FDI, horizontal FDI will be the least sensitive to employment protection legislation in the foreign country.

Export-platform FDI occurs when a multinational accesses a foreign market by setting up an affiliate in a neighboring country and exporting to the desired country (Ekholm, Forslid, and Markusen 2003, Yeaple 2003). The motivation is still to access a foreign market but now one foreign affiliate can export to a variety of neighboring countries. Thus, the multinational can access multiple markets with one well placed foreign affiliate. Under export-platform FDI, the relevant choice set facing the MNE is to produce at home and export or to produce in one of many potential host countries and export to multiple markets within a region. Since there are more options available to the MNE, export-platform FDI will be more sensitive to employment protection legislation than horizontal FDI.

Finally, vertical FDI occurs when multinationals invest in a country in order to take advantage of low foreign factor prices and minimize costs (Helpman 1984). The MNE shifts a part of the production activities to the foreign affiliate and then ships the output back to the home country for further processing or for final sales. Unlike horizontal and export-platform FDI which need to be near a specific foreign market, vertical FDI can be located in any foreign country regardless of location. The MNE simply chooses to invest in the country that generates the greatest cost savings. If the costs associated with operating in one foreign country increase, the MNE can shift these production activities to any other foreign country. Given that the motivation for vertical FDI is to take advantage of low foreign factor prices, vertical FDI will be especially sensitive to changes in the cost of production. Thus, relative to horizontal and export-platform FDI, vertical FDI will be the most responsive to employment protection legislation.

The key prediction is that the more footloose the FDI, the more sensitive FDI will be to increases in labor restrictions in the foreign country. As employment protection increases in

the foreign country, multinational will be reluctant to shift horizontal FDI elsewhere since that would defeat the main motivation of accessing that foreign market. However, with export-platform FDI the multinational has the ability to shift production to neighboring countries as labor restrictions increase. Finally, with vertical FDI the multinational has the ability to shift production to any other foreign country, regardless of location. The empirical analysis that follows examines whether FDI responds to employment protection legislation in this manner.

## 2.2 Assumption 2

The second assumption of the race to the bottom hypothesis is that countries competitively undercut each other's labor market standards in order to attract foreign investment. Given that FDI is often associated with increases in production, capital stock, infrastructure, and knowledge spillovers, attracting foreign investment is particularly appealing for foreign countries. If, according to assumption one, multinationals are attracted to countries with less restrictive labor standards, then each country has an incentive to lower their employment protection rules slightly below that of other countries. By undercutting the employment standards in other foreign countries, each host country has the ability to lure FDI away from its competitors. Thus, the second assumption of the race to the bottom hypothesis predicts that employment restrictions in a foreign country and the average labor standards in other countries are positively related. Specifically, as the weighted average of employment protection rules among a countries competitors falls the foreign country will reduce its own employment protections in response. The analysis that follows discusses how this weighted average is constructed and examines whether countries competitively undercut each other's labor standards.

## 3 Specification

### 3.1 Testing Assumption 1

The analysis begins by examining whether FDI is sensitive to changes in employment protection in the foreign host country. To test this first assumption of the race to the bottom

hypothesis, the following equation will be estimated using ordinary least squares (OLS):

$$(1) \quad FDI_{c,t} = \alpha_1 EP_{c,t-1} + X_{c,t-1} \alpha_2 + \lambda_c + \theta_t + \epsilon_{c,t}.$$

where  $FDI_{c,t}$  is U.S. foreign direct investment into country  $c$  in year  $t$ . The variable  $EP_{c,t-1}$  is employment protection in foreign country  $c$  and  $X_{c,t-1}$  is a vector of control variables that includes host country characteristics such as GDP, population, trade costs, skill level, tax rate, and investment costs. These variables are lagged to account for the fact that multinationals cannot immediately adjust FDI in response to these host country characteristics.<sup>2</sup> The natural log of all variables is used in the empirical analysis which allows for a more intuitive interpretation of the results. Finally,  $\lambda_c$  and  $\theta_t$  are country and year fixed effects respectively.

A second empirical strategy is to estimate a dynamic panel model, where current FDI depends on the lagged value of FDI. This accounts for the possibility that FDI is persistent over time. Thus, adding lagged FDI to equation (1) and first differencing leads to the following estimation equation:

$$(2) \quad \Delta FDI_{c,t} = \beta_1 \Delta EP_{c,t-1} + \Delta X_{c,t-1} \beta_2 + \beta_3 \Delta FDI_{c,t-1} + \Delta \theta_t + \Delta \epsilon_{c,t}.$$

where the country fixed effects are subsumed by the annual differences. The issue with estimating this equation is that the differenced residual,  $\Delta \epsilon_{c,t}$ , is by construction correlated with the lagged dependent variables,  $\Delta FDI_{c,t-1}$ , since both are functions of  $\epsilon_{c,t-1}$ . Similarly,  $\Delta EP_{c,t-1}$  and the control variables  $\Delta X_{c,t-1}$  may also be correlated with  $\Delta \epsilon_{c,t}$ . Therefore, OLS regressions of equation (2) can produce inconsistent estimates. To avoid this problem and to address potential endogeneity concerns, equation (2) will be estimated using the Arellano-Bond GMM estimator. This estimation strategy instruments the differenced variables that are not exogenous with their respective lagged levels (Holtz-Eakin, Newey,

---

<sup>2</sup>The results are similar if these variables are not lagged.

and Rosen 1988, Arellano and Bond 1991). This allows a causal impact of employment protection legislation on foreign direct investment to be identified.

Despite the inclusion of country and year fixed effects, lagging all the independent variables, and using the Arellano-Bond GMM estimation strategy, there may be lingering endogeneity concerns.<sup>3</sup> To address these concerns, it is possible to estimate equation (1) using the instrumental variable (IV) estimation strategy. This third empirical strategy uses the unionization density and the political ideology and strength of the ruling party as instruments for employment protection legislation in the foreign host country. A country with a declining union presence may, as a result, see an increase in governmental employment restrictions. Thus, changes in union density will be an important predictor of the employment protection legislation implemented in the foreign host country. In addition, a country with a more liberal ruling party will be more likely to implement labor market restrictions. Thus, changes in the ruling party and its relative strength will be an important predictor of employment protection. These instruments will identify an exogenous source of variation in labor market restrictions which is unrelated to FDI. This mitigates endogeneity concerns and allows the impact of employment protection on FDI to be identified. The construction of both instrumental variables will be discussed in greater detail in Section 4.4.

Given the theoretical motivation discussed in Section 2, we would expect  $\alpha_1 < 0$  and  $\beta_1 < 0$ . As employment protection increases, the costs of operating a foreign affiliate increase, and thus FDI decreases as the multinational shifts these production activities elsewhere. In addition, the magnitude of  $\alpha_1$  and  $\beta_1$  will depend crucially on the type of FDI. Thus, all three empirical strategies will be separately estimated using total FDI, horizontal FDI, export-platform FDI, and vertical FDI as the dependent variables. The coefficients on employment protection should be more negative as the degree of mobility exhibited by each type of FDI increases. Specifically,  $\alpha_1$  and  $\beta_1$  will be most negative in the vertical FDI regression, it will be least negative in the horizontal FDI regression, and it will fall between these extremes in the export-platform FDI regression.

---

<sup>3</sup>The race to the bottom hypothesis assumes that country's employment protection legislation reponds to other countries standards not one's own level of FDI. Furthermore, it is not entirely clear how FDI would affect employment protection legislation. Perhaps an increase in FDI encourages host countries to increase employment restrictions to protect local workers from being exploited by foreign multinationals or maybe increases in FDI encourage host countries to decrease employment restrictions to attract more FDI.

## 3.2 Testing Assumption 2

To test the second assumption of the race to the bottom hypothesis, this paper examines whether employment protection legislation is a function of employment protection in other foreign countries. Specifically, the following equation is estimated:

$$(3) \quad EP_{c,t} = \phi_1 \text{Competitor\_}EP_{c,t-1} + X_{c,t-1}\phi_2 + \phi_3 EP_{c,t-1} + \lambda_c + \theta_t + \epsilon_{c,t}.$$

where the dependent variable,  $EP_{c,t}$ , is employment protection in foreign country  $c$ .  $\text{Competitor\_}EP_{c,t-1}$  is the weighted average of employment protection in other foreign countries. This variable is constructed using three different weighting techniques which will be discussed in greater detail in the section that follows.  $X_{c,t-1}$  is a vector of control variables and the lagged value of employment protection is included as a regressor to account for the fact that employment protection rules are persistent over time.  $\lambda_c$  and  $\theta_t$  are country and year fixed effects respectively. Finally, all variables are in natural logs and the independent variables are lagged to account for the fact that changes in employment protection legislation take time to implement.

Equation 3 will be estimated using the OLS, Arellano-Bond GMM, and IV estimation strategies. The weighted average of the unionization and political ideology variables will be used as instruments in the IV regressions. If the race to the bottom theory is important, then  $\phi_1 > 0$ . As other foreign countries lower their employment protection rules, country  $c$  will respond by reducing its own employment protections in order to undercut its competitors.

## 4 Data

### 4.1 Foreign Direct Investment

Foreign direct investment is measured as U.S. direct investment abroad using data from the Bureau of Economic Analysis (BEA). Focusing on multinationals from one country is appealing because it minimizes parent country characteristics that may influence outward FDI. In addition, data on U.S. multinational companies is more comprehensive and detailed

than FDI data from other countries. There is little reason to believe that the determinants of U.S. FDI are fundamentally different from the decisions facing multinationals in other countries.

Another especially appealing aspect of the BEA data is that the measure of FDI used in this analysis (i.e. affiliate sales) allows for horizontal, export-platform, and vertical FDI to be separately examined. Specifically, the BEA identifies the ultimate destination of the sales by U.S. foreign affiliates. Affiliate sales to the local market measures horizontal FDI, affiliate sales to other foreign countries measures export-platform FDI, and affiliate sales back to the U.S. measures vertical FDI.<sup>4</sup> As mentioned before, the impact of employment protection on FDI should become more negative as the type of FDI becomes relatively more mobile. Finally, these FDI measures are converted into real dollars using the chain-type price index for gross domestic investment.<sup>5</sup>

## 4.2 Employment Protection

Data on employment protection comes from the Organisation for Economic Co-operation and Development (OECD). The OECD constructs a composite index of employment protection from seventeen individual measures of hiring and firing costs. These seventeen basic measures can be grouped into two broad categories, restrictions against firing workers and restrictions on hiring temporary workers. The firing restrictions include measures such as the notification process and timing of dismissals, the severance pay required, and the procedures for contesting an unfair dismissal. The hiring restrictions include measures such as the allowable number and duration of fixed term contracts, the type of work that temporary workers can do, and whether regular and temporary workers are treated equally.<sup>6</sup> The employment protection index is measured on a scale of zero to six with six representing the most restrictive rules.

While this composite index certainly does not capture all relevant factors that influence

---

<sup>4</sup>There are many other types of 'complex' FDI that are variations of these three basic components (Yeaple 2003). While these three categories may include more complex types of FDI, this will not fundamentally change the basic ordering of these types of FDI from less-mobile to more-mobile.

<sup>5</sup>This price deflator is found in the Economic Report of the President (<http://www.gpoaccess.gov/eop/tables10.html>).

<sup>6</sup>For further details on the components of these measures and how they are calculated, see the methodology section of the OECD Indicators of Employment Protection website at [www.oecd.org/employment/protection](http://www.oecd.org/employment/protection).

labor market flexibility, it does have some appealing aspects. First and foremost, it is an objective and consistent estimate of employment protection regulations in a wide variety of countries. Changes in this measure of employment protection represent legislative and policy changes in the host country that are more likely exogenous to foreign affiliate sales.<sup>7</sup> Second, while this measure may not explicitly include all relevant labor market restrictions, it represents a useful proxy for the overall employment conditions in the host country. Third, it is possible to separate this index into its hiring and firing sub-categories which proves useful in the analysis that follows. Finally, this employment protection measure is available for thirty countries and twenty four years (1985-2008). The scale and scope of this variable represents an important improvement over other measures.<sup>8</sup>

### 4.3 Control Variables

The estimation strategy implemented in this analysis controls for both country and year fixed effects. To account for factors that may vary within a country over time, a variety of additional control variables are included that are likely to influence the decision of a multinational to pursue FDI. Perhaps most important is the host countries real GDP which is obtained from the OECD. The population of the host country also comes from the OECD. Following Blonigen et al. (2007), I measure host country trade costs as the inverse of the openness measure reported by the Penn World Tables (PWT).

Data on the host country skill level is obtained from the Barro and Lee (2010) Educational Attainment Dataset. They report the average year of schooling for those over 25 years old every five years from 1950-2010. The intervening years are calculated using linear interpolation. Host country corporate income tax rates come from the OECD. Investment costs in the host country are measured using data from the Business Environment Risk Intelligence (BERI). Investment costs are calculated as the inverse of the composite index which includes the operations risk index, the political risk index, and the remittance and

---

<sup>7</sup>While changes in employment protection legislation is infrequent in some countries, when these changes occur they represent an important shift in labor market restrictions.

<sup>8</sup>Other authors (Gorg 2005, Dewit et al. 2009, Di Tella and MacCulloch 2005) have used data from the Global Competitiveness Report (GCR) produced by the World Economic Forum. This measure of hiring and firing costs is obtained from surveying local business managers about the hiring and firing practices in their country. This is relatively subjective and noisy measure which may not necessarily reflect changes in labor market legislation in the foreign host country.

repatriation factor index. Together, these control variables represent the factors that have been generally identified as important determinants of FDI.

#### 4.4 Instruments

The IV analysis uses the unionization density and the political ideology of the ruling party as instruments for employment protection. Data on the unionization rate in the foreign host country comes from the OECD and is calculated as the share of total wage and salary earners that are trade union members. As discussed previously, a lower unionization density increases the need for labor market regulations.

Data used to construct the political ideology variable comes from the Political Constraint Index (POLCON) Dataset (Henisz 2002). First, the political ideology of the political party that controls the executive branch of the government is identified. Each ruling political party is identified as liberal, neutral, or conservative. Then this ideology variable is interacted with a measure of political constraint which reflects the relative strength of the ruling party. Specifically, the political constraint variable takes into account the number of branches within the government that have veto power over policy changes, the party alignment across the branches of government, and the party heterogeneity within the legislative branches of government. This modified political ideology variable takes on values between one and three. Values close to three indicate that a relatively powerful liberal party is in control, values close to two indicate a relatively weak or neutral party is in control, and values close to one indicate that a relatively powerful conservative party is in control. A ruling party that is more liberal and powerful is more likely to implement employment protection legislation.

#### 4.5 Competitor Employment Protection

The employment protection measure from the OECD is used to construct the average of employment protection in other foreign countries. Specifically, for country  $c$  the *Competitor\_EP* variable is calculated as the weighted average of employment protection in all other foreign countries in the sample, not including country  $c$  itself. There are three different methods used to construct this average.

First, this variable is constructed as the unweighted average of employment protection in the other foreign countries. This method weights equally all other foreign countries. Second, *Competitor\_EP* is constructed using the inverse of distance between country  $c$  and the other foreign host countries as weights. The weights are normalized to one to account for the fact that the sample of countries changes over this period.<sup>9</sup> The employment protection legislation in countries that are closer in proximity to country  $c$  are weighted more heavily. Using the inverse of distance as weights is a common method for calculating spatial variables.

Rather than weighting countries that are closer in proximity more heavily, the third method weights more heavily those countries that are likely competing with country  $c$  for FDI. Specifically, the average vertical and export-platform FDI sales in each foreign country is used as a weight. The weights are normalized so that employment protection in those countries that have a greater share of vertical and export platform FDI sales are weighted more heavily. If these types of FDI are more mobile, then country  $c$  will be more responsive to changes in employment protection rules in countries that have a larger share of this type of FDI. In other words, these foreign countries will be the ones that country  $c$  is competing against to attract these relatively mobile types of FDI.

## 4.6 Descriptive Statistics

Combining these various measures, generates an unbalanced panel data set that spans twenty six countries and twenty three years (1985-2007).<sup>10</sup> The twenty six countries in this sample accounted for 78% of U.S. FDI in 2000. Table 1 reports the summary statistics of the variables used in this analysis. While the sample includes only OECD countries, Table 1 indicates there is substantial variation in all of these measures. For instance, real affiliate sales varied from \$1,165 million in Turkey in 1985 to \$586,295 million in the United Kingdom in 2007. On a scale of zero to six with six being the most restrictive, employment protection ranges from 0.6 in the United Kingdom in the 1990s to 4.2 in Portugal in the

<sup>9</sup>The results that follow are similar if the sample is restricted to countries that have data for the entire period.

<sup>10</sup>The countries include Australia, Austria, Belgium, Canada, Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Japan, Korea, Mexico, New Zealand, Netherlands, Norway, Poland, Portugal, Spain, Sweden, Switzerland, Turkey, and the United Kingdom.

late 1980s.

Figure 1 plots the annual average of employment protection against the annual average of real affiliate sales. A significant negative relationship between employment protection and affiliate sales is evident in Figure 1. Over time there has been a rough trend towards a decrease in employment protection rules and an increase in U.S. foreign affiliate sales.

Figure 2 plots the country average of employment protection against the country average of real affiliate sales. The U.K. and Canada have relatively lax employment protection rules and have high foreign affiliate sales. However, countries such as Portugal, Turkey and Greece have had strict employment protection rules and low levels of U.S. foreign affiliate sales. Perhaps not surprisingly, France and Germany have strict employment protection rules but high levels of affiliate sales. Again, there is a strong negative relationship between employment protection and affiliate sales. Countries that have strict employment protection rules typically have less U.S. foreign affiliate sales.

Figure 3 plots the country average of employment protection against the country average of different types of real affiliate sales. Two observations are worth noting. First, there is interesting variation across countries in terms of which type of FDI is most important. Not surprisingly, Japan and Australia have relatively large shares of horizontal FDI, Ireland and Switzerland have relatively large shares of export-platform FDI, and Mexico has a relatively large share of vertical FDI. Second, a negative relationship between employment protection and all three types of FDI is evident in Figure 3. However, it appears that the relationship between employment protection and vertical FDI is most negative, which is consistent with the intuition from Section 2.

Figures 1-3 provide insight into the dimensions and characteristics of the data set used in this analysis. It is interesting that such a strong negative relationship emerges in these basic scatter-plots. However, there are some important limitations of these scatter-plots which the empirical analysis that follows is able to overcome. First, the country and year fixed effects will capture much of the variation evident in these figures. The analysis that follows exploits country variation over time to examine the impact of employment protection on foreign affiliate sales. Second, these figures do not account for other factors that are changing over time and may be affecting both affiliate sales and employment protection.

As discussed previously, a wide array of control variables will be included in the empirical analysis. Third, this negative correlation does not imply causation. Fortunately, the GMM and IV estimation strategies will identify a causal impact of employment protection on foreign affiliate sales. With these caveats in mind, it is surprising that such a consistently negative relationship emerges in Figures 1-3. The section that follows examines whether this relationship is robust to a more careful and rigorous analysis.

Finally, Figure 4 reports the annual average of employment protection (solid line) and the 95% confidence intervals (dashed lines). The average employment protection in this sample of twenty six countries fell from 2.45 in 1985 to 2.00 in 2008, a reduction of 18%. In addition, the 95% confidence intervals converged over this time period which indicates that the variation in employment protection across countries decreased from 1985 to 2008. Both of these stylized facts are consistent with the second assumption of the race to the bottom hypothesis. However, this does not imply causation nor is it the only plausible explanation. The analysis that follows, identifies to what extent this reduction is driven by countries competitively undercutting each others labor standards.

## 5 Results

The goal of this analysis is to examine whether FDI responds to employment protection legislation and whether countries competitively undercut each other's labor standards. This section tests these two predictions of the race to the bottom hypothesis. First, the impact of employment protection restrictions on foreign affiliate sales to different locations is examined. Second, I examine whether countries competitively reduce their employment restrictions in response to changes in employment restrictions in other foreign countries.

### 5.1 Assumption 1 Results

The first assumption of the race to the bottom hypothesis is tested using the OLS, Arellano-Bond GMM, and IV estimation strategies. The OLS results obtained from estimating equation (1) are reported in Table 2. The results in column 1 indicate that more restrictive employment protection rules lead to a significant reduction in foreign affiliate sales. Given

the log-log specification, a 1 percent increase in employment protection leads to a 0.2 percent decrease in foreign affiliate sales. This is consistent with the idea that employment protection legislation increases the costs of operating in the host country and thus reduces U.S. FDI to that foreign country.

Columns 2-4 of Table 2 separate foreign affiliate sales by the ultimate destination of these sales. The results in column 2 indicate that employment protection reduces foreign affiliate sales to the local host country (horizontal FDI). The results in column 3 indicate that employment protection does not have a significant impact on foreign affiliate sales to other foreign countries (export-platform FDI). Finally, the results in column 4 indicate that employment protection has a large, negative impact on foreign affiliate sales back to the U.S. (vertical FDI). These findings provide preliminary support for the intuition discussed in section 2. Specifically, employment protection legislation has the strongest negative impact on the most mobile type of FDI. However, the GMM and IV estimation strategies will be better at identifying a causal impact of employment protection on FDI.

The coefficients on GDP, trade costs, skill, and investment costs are all significant and of the expected sign. Foreign direct investment increases with the size of the foreign economy, with reductions in trade costs, with reductions in the average skill level, and with reductions in investment costs. Consistent with other studies, GDP has a stronger positive impact on horizontal FDI while trade costs, skill, and investment costs have a stronger negative impact on vertical FDI. While the population and tax rate are typically thought to be important determinants of foreign direct investment, the coefficients on these variables are found to be insignificant. This may be because the country fixed effects and year fixed effects are capturing the variation in these control variable.

The Arellano-Bond GMM results obtained from estimating equation (2) are reported in Table 3. Employment protection has a negative impact on total foreign affiliate sales, but this relationship is only significant at the ten percent level (see column 1). More importantly, the impact of employment protection on different types of affiliate sales is consistent with the predictions from section 2. In column 2, employment protection does not have a significant impact on sales to the local market (horizontal FDI). This is consistent with the idea that horizontal FDI is not sensitive to host country employment protection restrictions. U.S.

multinationals want to access this foreign market and are thus relatively unresponsive to changes in employment protections in the host country.

In column 3, employment protection has a negative and significant effect on affiliate sales to other foreign countries (export-platform FDI). With export-platform FDI, U.S. multinationals can access a foreign market through a variety of different neighboring countries. Thus, as the employment protections become stricter in one host country, U.S. multinationals shift their affiliate production to another foreign country in that region.

In column 4, employment protection has large, negative, and significant impact on affiliate sales back to the U.S. (vertical FDI). Specifically, a 1 percent increase in employment protection leads to a 0.6 percent decrease in foreign affiliate sales to the U.S. With vertical FDI, U.S. multinationals are not constrained geographically by the need to access a foreign market. Thus, if the costs of operating foreign affiliates increase due to employment protection restrictions, the U.S. multinational simply relocates affiliate production to another cheaper foreign location. Finally, the lagged sales coefficients in all regression in Table 3 are positive and significant which indicates that sales are persistent over time. The high p-values on the Hansen J and second order autocorrelation (AR2) tests indicate that the lags of the dependent variables are in fact exogenous and are thus good instruments.<sup>11</sup>

Finally, equation (1) is estimated using the IV estimation strategy. Table 4 reports the first stage IV results for all four sales regressions.<sup>12</sup> As expected, the unionization rate has a negative affect on employment protection. As the prevalence of unions decreases, there is more need to protect workers through government imposed labor market restrictions. Also consistent with expectations, the political ideology variable has a positive impact on employment protection. A strong liberal government is more likely to implement labor market restrictions. The F-stat on the excluded instruments is above 40 in all the regressions, which indicates relatively strong instruments.

---

<sup>11</sup>However, the Hansen J test can be weakened when, as a rule of thumb, the number of instruments exceeds the number of groups (i.e. countries). This is the case in this analysis because there are a relatively large number of years which increases the instrument matrix. However, this does not affect the coefficient estimates (Roodman 2006) and the results in Table 3 are not sensitive to reducing the number of lagged instruments used in the GMM estimation strategy.

<sup>12</sup>Although similar, the first stage results are not the same for the different IV regressions because the sample size changes depending on which foreign affiliate sales dependent variables is used in the second stage.

The second stage IV results are reported in Table 5. Once again, employment protection decreases foreign affiliate sales. Furthermore, consistent with expectations, employment protection has a progressively more negative impact on local sales, foreign sales, and U.S. sales. Not surprisingly, employment protection legislation has the most negative impact on the relatively more mobile types of FDI. In addition, the magnitudes are large. A 1 percent increase in employment protection leads to a 3 percent decrease in affiliates sales back to the U.S. Vertical FDI is most sensitive to labor costs in foreign countries and thus labor market restrictions have the largest impact on this type of FDI. Finally, the overidentification test (i.e. the Hansen J p-value) indicates that the instruments are uncorrelated with the error term and are thus valid instruments. The results in Table 5 provide clear and convincing evidence that FDI decreases with employment protection legislation in the foreign host country.

Overall, the results in Tables 2-5 support the first assumption of the race to the bottom hypothesis. As employment protection legislation decreases, foreign direct investment increases. In addition, as the type of FDI becomes more mobile, the relationship between employment protection and foreign affiliate sales becomes larger in magnitude and more significant. This is an important result and indicates that the multinational response to employment protection depends crucially on the type of FDI. Furthermore, these key results are robust across the OLS, GMM, and IV estimation strategies.

## 5.2 Assumption 2 Results

The results so far indicate that FDI, particularly export-platform and vertical FDI, increases as employment restrictions are relaxed. This provides a motivation for foreign host countries to competitively undercut each other's labor standards. To test this second key assumption of the race to the bottom hypothesis, equation 3 estimates the impact of employment protection rules in competing foreign countries on the host country's own employment protection legislation. The results of this analysis are reported in Tables 6, 7, and 8.

Table 6 reports the results when *Competitor\_EP* is constructed as an unweighted average of other foreign country's employment protection rules. Column 1 reports the OLS results, column 2 reports the Arellano-Bond GMM results, and column 3 reports the

IV results using the unweighted average of *union* and *ideology* as instruments.<sup>13</sup> In all regressions, the coefficient on lagged *Competitor\_EP* is insignificant. If the race to the bottom theory was important we would expect this coefficient to be positive and significant. A reduction in their competitor's labor standards would lead to a reduction in the foreign host countries employment restrictions. The lack of significant findings casts doubt on the assumption that countries are competitively undercutting each other's labor standards.

Table 7 shows the estimation results when *Competitor\_EP* is constructed as a weighted average using the inverse of distance between the two foreign countries as the weights. This places more emphasis on employment protection rules in foreign countries that are in close proximity to the foreign host country. The results in Table 7 once again indicate that, regardless of the estimation strategy used, *Competitor\_EP* has no significant impact on employment protection in the host country. However, the strong positive impact of lagged host country employment protection on current employment protection indicates that these labor standards are persistent over time.<sup>14</sup>

As discussed in section 4.5, it is also possible to construct *Competitor\_EP* using the share of average vertical and export-platform sales as weights. The first part of this paper finds that these types of FDI are most sensitive to changes in employment protection legislation. Rather than weighting countries based on geographic distance, this method weights more heavily employment protection in those foreign countries that have a larger share of these relatively mobile types of FDI. Presumably these are the foreign countries that the foreign host country is competing against for U.S. FDI. Table 8 reports the results using *Competitor\_EP* constructed in this manner. Again, the coefficient on *Competitor\_EP* is insignificant in the OLS and GMM specifications. However, it is significant and negative in the IV regression. This suggests that as the employment protection legislation in other foreign countries decreases, the employment protection rules in the host country increase. Thus, if anything, this finding works against the second assumption of the race to the bottom hypothesis.

---

<sup>13</sup>The first stage F-stat and the overidentification test in this IV regression indicates that these instruments are relatively weak.

<sup>14</sup>In addition, it is important to include the lagged host country employment protection as an additional control because the host country's EP level is not included in the calculation of *Competitor\_EP*.

Overall, there is no evidence that countries competitively undercut each other's labor standards, despite the fact that doing so would increase inward FDI. Perhaps changing economy wide labor standards is too blunt a tool to attract foreign investment. This key finding is robust to three different methods of constructing the competitor's employment protection variable and to three different estimation strategies. While there is evidence supporting the first assumption of the race to the bottom hypothesis, there is no evidence supporting the second assumption.

## 6 Extensions

The following extensions provide additional insight into the relationships between FDI, host country employment protection, and competitor's employment protection rules. Specifically, different components of affiliate sales to the U.S. and employment protection rules are examined. In addition, an alternate specification is used to test the second assumption of the race to the bottom hypothesis.

### 6.1 Affiliate Sales to the U.S.

Employment protection regulations have the strongest impact on foreign affiliate sales back the U.S. It is possible, given the BEA data, to take a closer look at the type of affiliate sales back to the U.S. most affected. Specifically, affiliate sales can be separated into those going to the U.S. parent and those going to unaffiliated U.S. parties. In addition, affiliate sales are separated into the sale of goods and the sale of services back to the U.S. The results using the IV estimation strategy are reported in Table 9.

The results using foreign affiliate sales to the U.S. parent as the independent variable are reported in column 2 and the results using foreign affiliate sales to unaffiliated U.S. parties as the independent variable are reported in column 3. The coefficients on employment protection are negative, significant, and similar in magnitude in both specifications. A 1 percent increase in employment protection leads to a 3.0 percent decrease in sales to the U.S. parent and a 2.6 percent decrease in sales to unaffiliated U.S. parties. If anything, employment protection has a slightly more negative impact on affiliate sales back to the

U.S. parent. This suggests that FDI whose output is shipped back to the U.S. parent for further processing is more mobile than FDI whose output is sold to U.S. consumers.

Columns 4 and 5 of Table 6 compare affiliate sales of goods and services back to the U.S. The results indicate that the sale of goods decreases in response to employment protection but there is no significant impact on the sale of services. While this points to an interesting distinction between affiliate sales of goods and services, these results should be interpreted with caution since data on affiliate sales of services is notoriously difficult to measure.

## 6.2 Employment Protection Components

Having taken a closer look at the dependent variable of interest, we now turn to the key independent variable (employment protection). As discussed previously, the employment protection measure from the OECD is an average of firing and hiring costs assembled from seventeen individual components. It is possible to separately examine the impact of firing restrictions and hiring restrictions on the foreign affiliate sales to the U.S. By definition these firing and hiring components have less variation than the composite index. However, no change in these employment restriction measures within a country still represents an important source of variation or counterfactual in this analysis.

Table 10 reports the IV estimation results from regressing U.S. sales on the firing and hiring components of employment protection. The results in columns 2 and 3 indicate that both firing and hiring costs decrease vertical FDI. A 1 percent increase in firing restrictions decreases affiliate sales to the U.S. by 4.3% and a 1 percent increase in restrictions on hiring temporary workers decrease affiliate sales to the U.S. by 2.3%. The slight difference in the size of the coefficients suggests that firing restrictions are a greater deterrent for FDI than restrictions on hiring temporary workers. However, overall, the additional costs associated with both firing and hiring workers leads U.S. multinationals to relocate their affiliate production activities elsewhere.

## 6.3 Contemporaneous Competitor Employment Protection

The results reported in Tables 6-8 assumed that there is a lag in the response of host countries employment protection rules to changes in their competitor's employment protection

rules. It is assumed that it takes time for countries to respond to their competitor's actions and to implement these changes. However, if the host country can anticipate changes in labor standards in other foreign countries, then the host country can respond quickly by lowering its own standards within the given year. While somewhat less plausible, this section examines this possibility in greater detail.

To test for this possibility, the following spatio-temporal model is estimated:

$$(4) \quad EP_{c,t} = \rho \cdot W \cdot EP_{c,t} + X_{c,t-1}\phi_2 + \phi_3 EP_{c,t-1} + \lambda_c + \theta_t + \epsilon_{c,t}.$$

This is similar to equation 3 except now the components of the contemporaneous *Competitor\_EP*, the spatial autoregressive term, is explicitly stated as the product of the spatial lag weighting matrix,  $W$ , and employment protection. As discussed before,  $W$  is constructed as the row normalized unweighted average, the row normalized weighted average using the inverse of distance, and the row normalized weighted average using average affiliate sales. Finally,  $\rho$  is the parameter to be estimated. While similar to equation 3, this notation is used here to be consistent with the spatial econometrics literature.

This equation is estimated using the maximum likelihood (ML) estimation strategy (Blonigen et al. 2007). OLS estimates of equation 4 are inconsistent because by construction the spatial autoregressive term and the error term are correlated. However, this is not a problem if the spatial autoregressive term is temporally lagged, as is the case in equation 3 (Franzese and Hays 2008).

The results from estimating equation 4 are reported in Table 11. *Competitor\_EP* is now contemporaneous while all other control variables remain temporally lagged. The results indicate that changes in the competitor's employment protection rules has a negative and significant impact on the host country's employment protection rules. This result is not sensitive to the weighting method used to construct the  $W$  matrix. This is a somewhat surprising result and is at odds with the second assumption of the race to the bottom hypothesis which predicts a positive coefficient. Specifically, we would expect that reductions in competitor's labor standards would cause the host country to competitively lower

their own labor standards in response. Instead, the results in Table 11 indicate the exact opposite. The host country raises their labor standards in response to lower competitor labor standards. This interesting result warrants further examination which is left to future research. For the purposes of this paper, these results confirm earlier findings and once again indicate that there is no evidence that countries are competitively undercutting one another's labor standards.

## 7 Conclusion

There are two implicit assumptions in the race to the bottom hypothesis. The first assumption is that multinationals will increase their foreign investment in response to reductions in employment protection in the host country. Furthermore, the relatively mobile types of FDI will be most responsive to employment protection rules. The second assumption is that countries competitively undercut each other's labor standards in order to attract FDI.

The empirical results presented in this paper confirm the first assumption. Specifically, there is a significant negative impact of employment protection on FDI. A reduction in employment protection rules leads to an increase in foreign affiliate sales. In addition, this negative relationship is strongest among the most mobile types of FDI. Employment protection legislation in the host country has limited impact on horizontal FDI, a more substantial negative impact on export-platform FDI, and a large, negative impact on vertical FDI.

Despite the fact that lowering employment restrictions increases FDI, there is no evidence that countries are competitively undercutting each other's labor standards to attract foreign investment. Specifically, this paper examines whether labor standards in other foreign countries affect the employment restrictions in the foreign host country. Regardless of the weighting method used to construct the foreign countries' labor standards or the estimation strategy, there is no significant impact on the host country's employment protection rules. Overall, this paper finds support for the first proposition of the race to the bottom hypothesis but no evidence of the second assumption.

Whether this is a desirable outcome depends on one's view of employment protection.

If labor market restrictions are necessary to protect the rights of workers, then this is an encouraging result. Although multinationals are investing in countries with the least restrictive regulatory conditions, there is no evidence that this is promoting a race to the bottom. However, if labor market restrictions are undesirable and hinder economic flexibility and growth, then the finding that countries are not competitively lowering employment restrictions is discouraging. Although attracting foreign investment provides an incentive for countries to liberalize their labor markets, to date countries are not competing with one another to do so. Regardless of one's perspective on labor market restrictions, this paper provides important evidence that FDI does respond to regulatory standards but that countries are not competitively lowering standards to attract FDI.

## ASSESSING THE GAINS FROM STRUCTURAL REFORMS FOR JOBS AND GROWTH

*Derek Anderson, Bergljot Barkbu, Lusine Lusinyan, and Dirk Muir*

### Structural Reforms and Gaps in Euro Area Countries

Euro area countries, particularly those in the periphery, have made strong progress on their structural reform agendas since the global financial crisis. The crisis created the impetus to implement difficult, but needed, structural reforms. In particular, important labor market reforms aimed at reducing labor adjustment costs and promoting employment have been put in place in Greece, Italy, Portugal, and Spain, while countries in the core have primarily focused on increasing labor force participation, for example, through pension reform. Product market reforms have pursued market liberalization and deregulation, mainly in the periphery, although the overall progress on implementing the European Union (EU) Services Directive has been slow in both the periphery and the core.

Progress has been impressive, but important structural gaps still exist, with specific priorities varying across countries.<sup>1</sup> Indicators of product market regulation and the degree of competition in various sectors of the economy suggest scope for easing regulation and strengthening competition in the euro area vis-à-vis the Organization for Economic Cooperation and Development (OECD) frontier cases. Although some euro area countries (notably, Ireland) are among the OECD best-practice cases, product markets are, on average, more heavily regulated and less open to competition in the euro area than in other advanced economies (Figure 7.1, left panel), reflected also in higher price markups, which is a proxy measure for the degree of competition, especially in services (Figure 7.1, right panel).

There is also significant scope for making European labor markets more inclusive, dynamic, and efficient, while recognizing that there is no single optimal labor market model. Employment protection is more stringent in the euro area than elsewhere in advanced OECD countries (Figure 7.2, left panel), which can have a negative impact on labor productivity (Bassanini, Nunziata, and Venn, 2009). Unemployment insurance is relatively more generous while retirement incentives encourage early exit from the labor force. In addition to labor adjustment costs, the tax wedge is high in most euro area countries, and reducing it by shifting taxation from direct to indirect taxes

---

Research assistance was provided by Pedro Espallat. The chapter builds on Barkbu and others (2012) and Lusinyan and Muir (2013).

<sup>1</sup> IMF (2013a) discusses the key priorities for euro area countries, based on in-depth country-specific analyses carried out by IMF country teams as part of economic surveillance or program work.

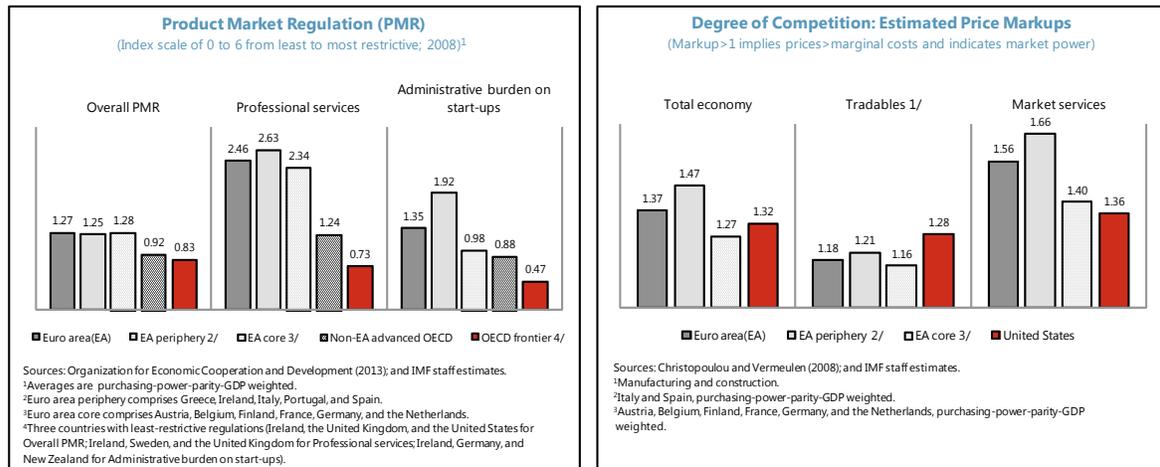

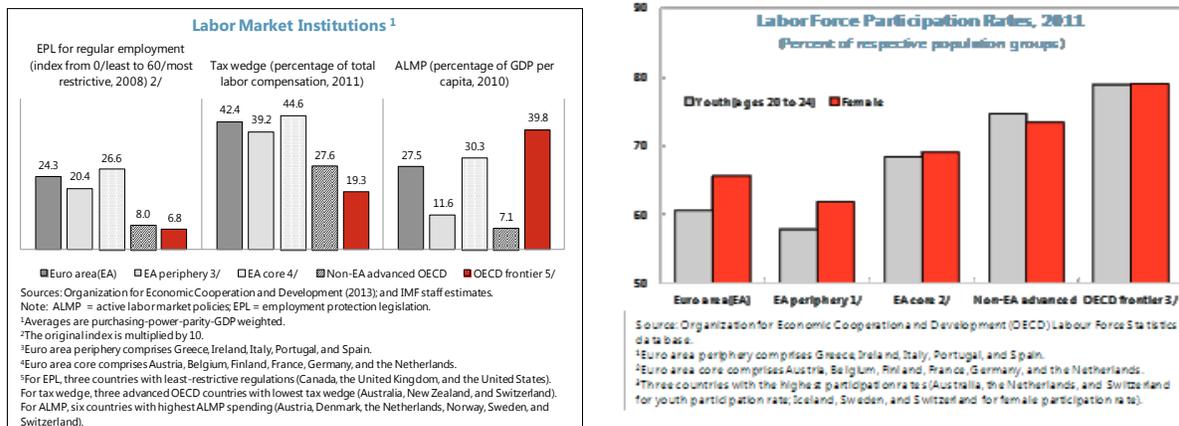

Figure 7.2 Selected Indicators of Labor Market Institutions and Performance

could further boost employment, growth, and competitiveness. The use and scale of active labor market policies vary across the euro area. Strengthening such policies, together with other measures to boost labor force participation (e.g., child care support), can have an important impact on employment, employability, and efficiency of job matching, which would help address the problems of low labor utilization, especially female and youth, that many euro area countries are facing (Figure 7.2, right panel).

## Quantifying the Impact of Structural Reforms

This chapter analyzes the potential macroeconomic impact of structural reforms that would help narrow the structural gaps in the euro area. For each of the euro area countries, the simulation models the impact of closing roughly 50 percent of the gap with OECD frontier cases in labor and product market policies as well as improving the functioning of the pension and tax systems. Product market reforms seek to reduce anticompetitive regulations, lower barriers to entry, and

increase competition. Labor market reforms are more varied, and include reducing employment protection legislation, reducing unemployment benefits, increasing child care support, implementing active labor market programs, and enacting pension-related reforms such as increasing the standard retirement age and increasing the incentive to work between the ages of 60 and 65. Finally, revenue-neutral tax reforms shift taxation from labor and corporate income to consumption. OECD empirical estimates of the dynamic effects of structural reforms on macroeconomic variables such as labor participation, unemployment, and productivity are used as inputs to the model to generate the estimates of the impact of reforms on real GDP.<sup>2</sup>

To quantify the impact, the IMF's Global Integrated Monetary and Fiscal model, a general equilibrium model that features nominal and real adjustment costs and incomplete asset markets, is used.<sup>3</sup> The model brings together economic agents that optimize freely (firms maximize profits, and households maximize utility based on a consumption-leisure choice) and liquidity-constrained agents that consume their income fully. The analysis in this chapter uses a six-region version, composed of the core euro area countries, the euro area periphery countries, the United States, emerging Asia, Japan, and the rest of the world.<sup>4</sup>

Several key features drive the short-term dynamics of the reform impact. The euro area core and periphery regions follow a common inflation targeting regime. Fiscal policy is independently determined in each region and is based on a policy rule that ensures long-term sustainability<sup>5</sup> while allowing for short-term countercyclical stabilization policies. The gradual implementation of reforms, combined with the gradual adjustment of labor supply and capital in response, drives the difference between short- and long-term effects. The simulations are conducted with monetary policy that accommodates the increase in inflation in the short term, complementing the positive effects on real GDP.

Households and firms are assumed not to believe initially that the government will successfully enact its reform agenda, which affects their behavior. Households and firms base their current decisions and expectations only on the reforms actually implemented up to that point. However, the government continues to implement its reforms each year, so households and firms continually update their decisions, gradually adjusting their expectations. After five years, households and firms are assumed to believe fully that the entire announced reform package will be implemented. This process of gradual acceptance affects the outcome in the short to medium term, but the long-term outcome will be the same as if households and firms immediately

---

<sup>2</sup> For a detailed discussion of the methodology used to obtain the empirical estimates of the impact of structural reforms, see, for example, Bouis and Duval (2011); updated estimates have been used in the simulations in this chapter.

<sup>3</sup> Kumhof and others (2010) and Anderson and others (2013) provide details on the theoretical foundations and properties of the Global Integrated Monetary and Fiscal model.

<sup>4</sup> In what follows, the euro area periphery comprises Greece, Ireland, Italy, Portugal, and Spain; the remainder of the euro area countries make up the core euro area.

<sup>5</sup> By doing so, this analysis abstracts from considerations of the way different sovereign debt levels may impact fiscal policy and its effects.

believe in the full implementation of the announced reform package (see the section titled Reform Implementation: Macroeconomic and Policy Environment).

The analysis has some limitations. In particular, employment is represented only as total hours worked, but it cannot be further decomposed into the unemployment rate, the participation rate, or average hours worked. The way the equilibrium wage is set does not allow involuntary unemployment to be captured. In addition, the analysis is conducted around an initial steady state that does not account for different cyclical or competitiveness positions across countries, which could affect the extent of possible reforms or their full effects. The estimates are therefore only illustrative examples of what might be achieved in the short and long terms. The section titled Reform Implementation: Macroeconomic and Policy Environment looks at how reform implementation and its impacts may be affected by policy credibility, price stickiness, and demand conditions.

### **The Benchmark Scenario**

Structural reforms can raise real GDP markedly, though the full effects of reforms only materialize with time. This section uses estimates of the distance from the OECD frontier cases to consider the scope and potential gains from reforms and constructs a benchmark scenario (see Table 7.1), using as a baseline the IMF's country-specific projections, as reflected in the April 2013 *World Economic Outlook*. The dynamic effects of different reforms on real GDP, employment, and competitiveness for the periphery and core euro area countries are discussed.

### **Product market reforms**

Euro area countries tend to have higher markups than other advanced economies, indicating substantial scope for gains from reforms. Reforms are assumed to close roughly half the gap between the countries' current regulatory burden and a frontier measure (defined differently for different reforms) within 13 years, but the reforms are front-loaded into the first 5 years (Table 7.1). The empirical estimates of the impact on productivity from reducing regulatory barriers are based on Boursès and others (2010), and take into account the short-term dynamics of reforms in Bouis and others (2012), as well as the estimates for markups from other sources, such as Forni, Gereli, and Pisani (2010). The regulatory burden indicators are estimated using the OECD's survey-based product market regulation index (Boylaud and Nicoletti, 2003). In the tradables sector, the indicators cover product market regulations, such as state control of business enterprises, legal and administrative barriers to entrepreneurship, and barriers to international trade and investment. The nontradables sector consists of retail trade, network industries, and professional services. The indicators for retail trade are barriers to entry, operational restrictions, and price controls; for professional services, they are barriers to entry and conduct regulation in the legal, accounting, engineering, and architectural professions; and for network industries they are barriers to entry and public ownership in the energy, transport, and communications sectors.

Increasing competition in the tradables and nontradables sectors in the euro area could raise the level of real GDP by 1¾ percent after five years and by more than 7 percent in the long term. The first-year impact on real GDP would, however, be limited to ¼ percent (Figure 7.3). Greater

## ASSESSING THE GAINS FROM STRUCTURAL REFORMS FOR JOBS AND GROWTH

Figure 7.3 Product Market Reforms

Sources: Global Integrated Monetary and Fiscal Model simulations using OECD and IMF staff estimates

Note: L.R. is the long run (2060).

competition would reduce the cost of goods and services to consumers, leading to an increase in consumption, investment, and exports. The increased demand for goods would increase firms' demand for factors of production, putting upward pressure on real wages. Employment would be lower because the stronger income effect outweighs the substitution effect, driven mostly by reforms in the tradables sector.

The euro area's competitiveness would slightly improve in the long term. With labor productivity almost 7 percent higher, unit labor cost would decline. In the long term, the euro would depreciate in real terms by almost 1 percent and the nominal trade balance would slightly improve after an initial deterioration driven by strong imports.

Gains from product market reforms are more extensive in the periphery than in the core. Almost half of the gains from product market reforms originate in the periphery, despite it representing only one-third of the economic size of the euro area (Table 7.2).

### ***Labor market reforms***

The benchmark scenario for labor market reforms comprises policies that increase labor supply and ease adjustment. Labor market institutions are a key reform priority, but involve many factors that need to be taken into account when charting a course for reforms and that may vary in importance across countries (Blanchard, Jaumotte, and Loungani, 2013). To model the impact of labor market reforms, estimates are used from Bassanini and Duval (2006), taking into account the short-term dynamics as found in Bouis and others (2012) for reforms to ALMP, unemployment, and EPL, and from Jaumotte (2003).

Active labor market policies (ALMP) aim to encourage the nonemployed to retrain and return to the labor market. The analysis assumes that countries increase the ratio of ALMP spending per unemployed to GDP per capita relative to the average within a set of countries with high ALMP spending (Denmark, Austria, the Netherlands, Norway, Sweden, and Switzerland). This assumption is implemented through a permanent increase in government spending for two years, financed through an increase in public debt and an increase in labor supply.

Unemployment insurance helps workers insure against unemployment, but may also lead to lower employment and longer unemployment duration. The impact of a reduction in the average replacement rate (ARR) of unemployment insurance benefits relative to the average within a set of countries with low replacement rates (Australia, Canada, Japan, New Zealand, the United Kingdom, and the United States) is considered. This impact is implemented in the model through a reduction in government spending and an increase in labor supply.

- *Employment protection legislation (EPL)* encourages stable employment relationships, but may also hamper the reallocation process, with a negative impact on productivity (e.g., Martin and Scarpetta, 2012). Countries are assumed to ease employment protection relative to the average of the three lowest levels observed across OECD economies. The impact of this easing is implemented using the OECD estimates of increased labor productivity in both the tradables and nontradables sectors.

- *Increased availability of public child care services* can increase labor supply, especially of women, by reducing the opportunity cost of employment. The analysis assumes that countries increase the ratio of public child care spending to GDP per capita relative to the average of countries with the highest public child care spending (Denmark, Norway, Sweden, and the United Kingdom). This increase in child care spending is modeled through a permanent increase in government spending for two years and an increase in labor supply.

Labor market reforms also cover pension reform. Pension reform would consist of both an increase in the retirement age by two years and a move to actuarial neutrality (a zero implicit tax rate on continued employment for workers between the ages of 60 and 65). This reform would lead to permanently lower pension outlays (represented by a reduction in transfers to liquidity-constrained households), allowing for a permanent reduction in government debt, and to an increase in labor supply.

The labor market reforms could have a positive but modest impact on real GDP of 1½ percent after five years and 3 percent in the long term. The short-term gain would be limited to ½ percent of GDP, but still double the impact of product market reforms (Figure 7.4). In the short term, households would perceive the changes in policies regarding ALMP, ARR, and child care as temporary, and would not fully commit to supplying more labor. Similarly, because productivity gains from EPL would not be fully realized in the short term, its impact would be marginal. Wages would fall in the medium term because the positive effects of higher demand for euro area goods, and hence for the factors of production, would still take time to materialize, but would still increase in the long term. The effects would also be apparent in the dynamics of consumption, which would decline notably after five years before increasing in the long term. In the long term, most of the increase would be driven by the reforms that boost labor supply. However, the productivity impact from EPL would be substantial, accounting for more than a quarter of the impact on real GDP.

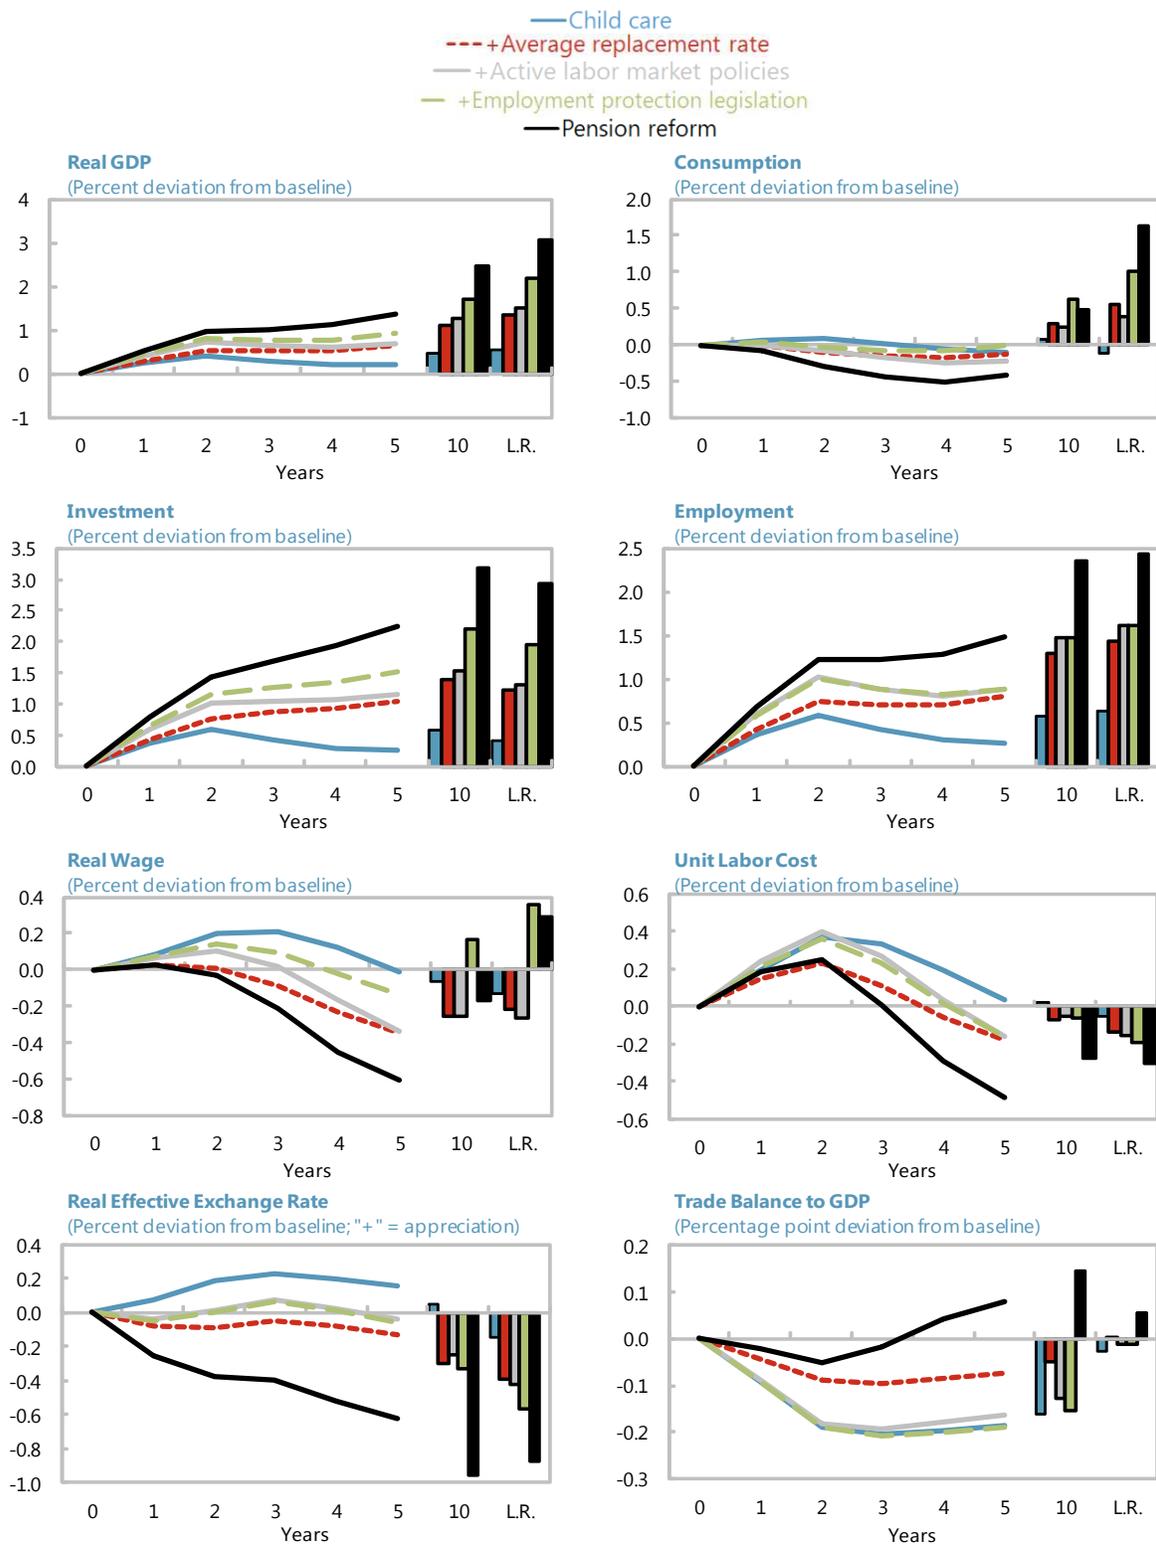

Euro area competitiveness and labor productivity would improve in the long term. Although there would be downward pressure on productivity from the increase in labor supply, it would be offset by the EPL reforms. Therefore, the unit labor cost is lower, reinforced by the decline in real wages resulting from higher labor supply. With more labor available for production, firms' demand for capital would also increase, and investment would be permanently higher. Cheaper goods being produced in the euro area would also lead to a permanent real exchange rate depreciation of almost 1 percent and a slightly stronger external position.

Labor market reforms would have a stronger short-term impact than product market reforms, but their effect would become relatively muted. According to OECD estimates, the euro area is not too distant from best practices in ALMPs and child care services. The effects of these reforms on productivity and GDP are empirically found to be relatively small (Barnes and others, 2011; Bouis and Duval, 2011).

However, the fiscal implications of labor reforms would be positive for the euro area. In the long term, the decrease in spending on pensions and unemployment insurance would lead to a fall in the level of government debt in the euro area as a whole of almost 20 percent of GDP (with the

ASSESSING THE GAINS FROM STRUCTURAL REFORMS FOR JOBS AND GROWTH

**Figure 7.4 Labor Market Reforms**

 Note: L.R. is the long run (2060).

largest reduction in debt occurring in the periphery countries). Because there would be less demand for global saving to maintain the level of euro area debt, the global interest rate would decline permanently, by about 10 basis points.

Labor market reforms would have a larger impact in the periphery than in the core. The long-term gains in real GDP would be  $3\frac{1}{2}$  percent in the periphery and  $2\frac{3}{4}$  percent in the core (Table 7.2). The periphery could gain most from reforms to unemployment insurance, female labor market participation, and pensions; for the core, the gains would be largest from reforms to EPL and pensions.

### **Revenue-neutral tax reforms**

Revenue-neutral tax reform shifts the tax burden away from distortionary direct taxes to indirect taxes, increasing the incentives to work and invest. In particular, “fiscal devaluation,” which is a budget-neutral shift from employers’ social contributions toward value-added taxes (VAT), has been shown in the empirical literature to increase output and employment (see, for example, IMF, 2012). Because labor-related tax revenues constitute a large share of the revenues in the euro area, transferring this burden to VAT would increase the incentive to work and to hire labor, leading to an increase in labor supply and real GDP (Allard and others, 2010). Similarly, a shift away from corporate income taxes to VAT would increase the return on capital, leading to higher investment and real GDP. Tax revenues can be increased by broadening the tax base as well as by increasing tax rates. The table below shows the size of the revenue-neutral tax reform that is assumed to be implemented in the core and the periphery of the euro area over two years, starting in 2013.

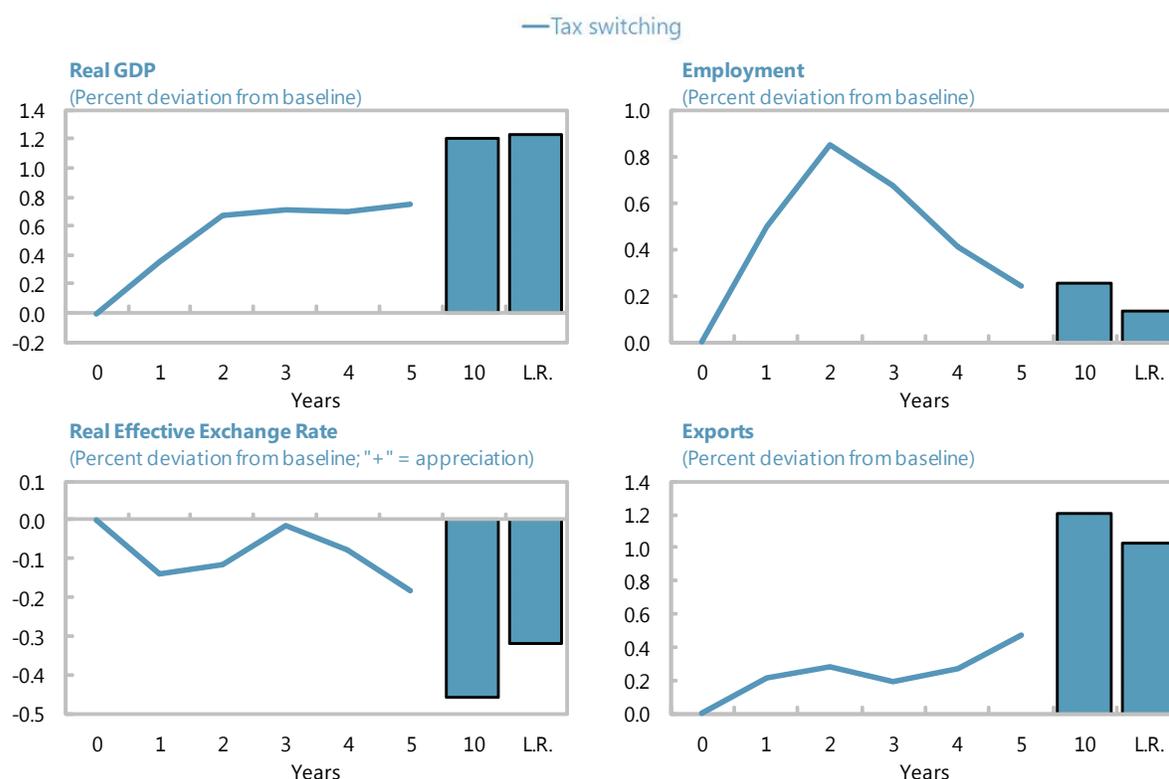

#### **Assumed Two-Year Change in Tax Instruments as a Share of GDP**

	Corporate Tax	Labor Tax	Value-Added Tax
Core	-0.75	-1.0	1.75
Periphery	-0.5	-0.75	1.25

A shift in taxation from direct to indirect taxes could raise real GDP by  $\frac{3}{4}$  percent after five years and  $1\frac{1}{4}$  percent in the long term. In the first year, GDP would be higher by almost  $\frac{1}{2}$  percent (Figure 7.5). The medium-term impact would be dampened because households and firms believe that the reforms are temporary. Therefore, although consumption tax increases would immediately affect consumers’ marginal propensity to consume, the direct tax cuts would not have as large an offsetting effect on household and firm behavior. Consumption would fall after five years, although it would increase in the long term. Employment, after a positive short-term reaction, would be only marginally higher in the long term (although the real wage would increase). Because the tax cuts would affect the cost of capital and labor directly, competitiveness would improve. The unit labor cost would fall slightly despite increasing real wages, exports would rise by about 1 percent in the long term, and the real exchange rate would depreciate.

An increase in consumption taxes would lower household consumption, but the positive effects from removing tax distortions would be much greater. In the long term, the labor income tax cut

Figure 7.5 Fiscal Reforms

Note: L.R. is the long run (2060).

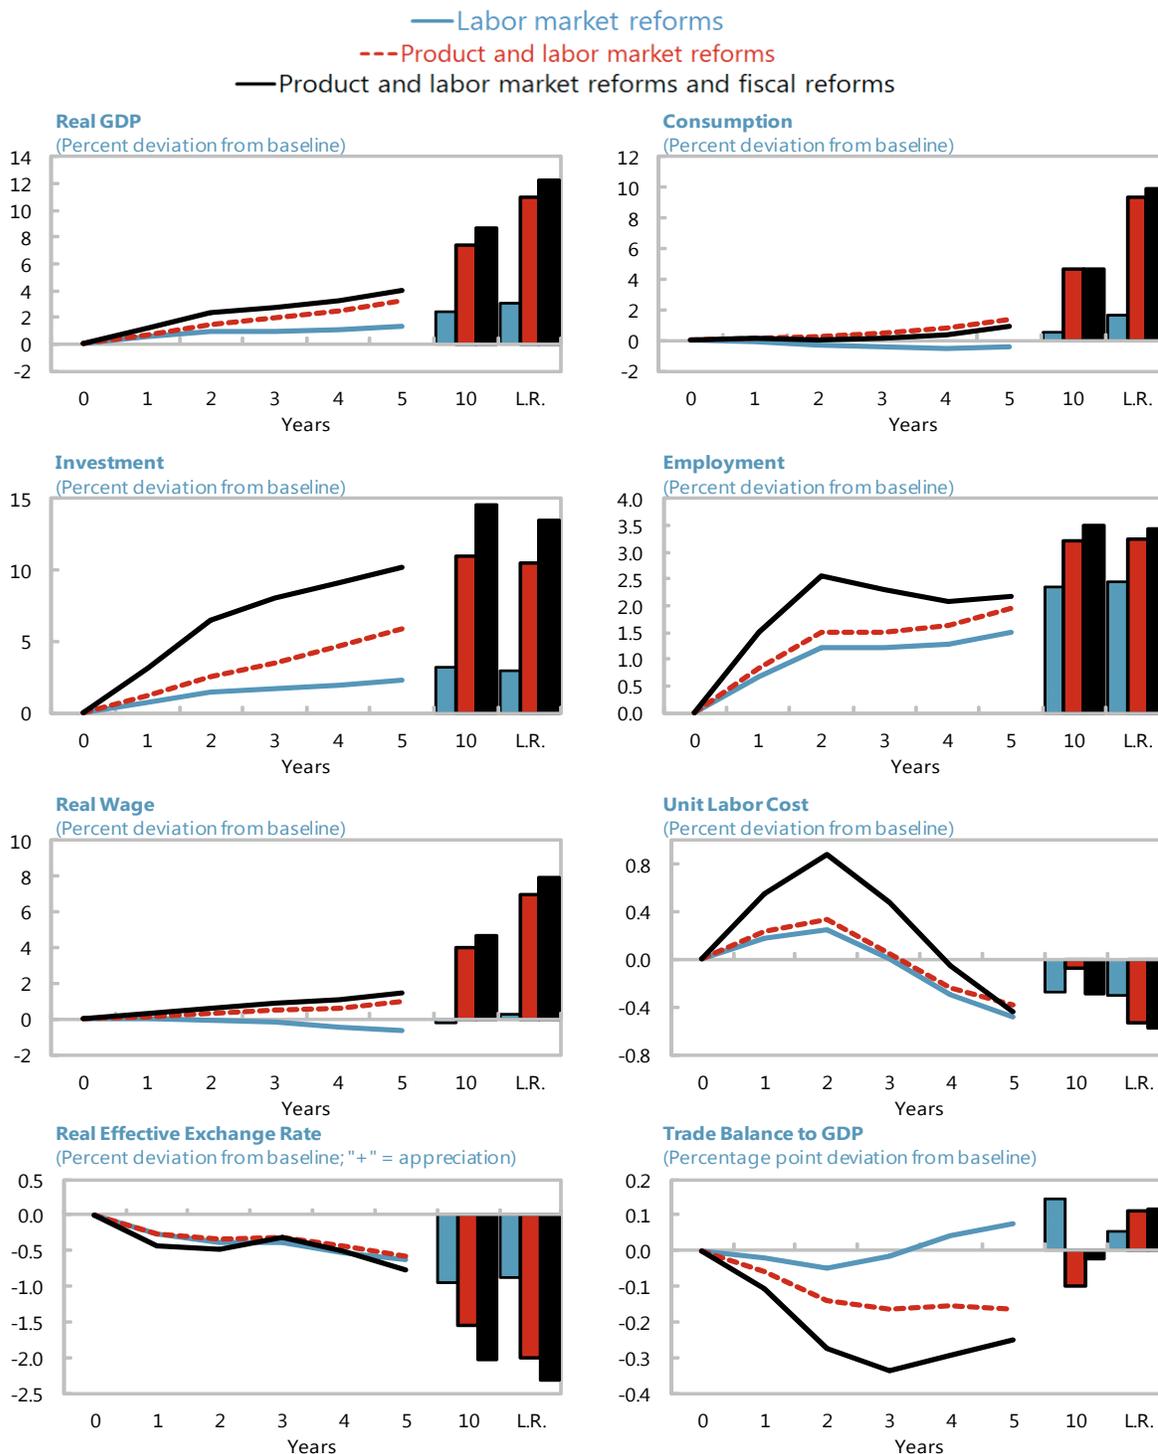

would offset the negative effects from consumption taxes on households' spending power and would provide an incentive for more labor supply. The corporate income tax cut would reduce the cost of capital faced by firms, encouraging greater demand for capital and labor. The assumption that firms only gradually believe in the implementation of the reforms would slow this process.

### **Combining all structural reforms**

Simultaneous implementation of product market, labor market, and tax reforms would be larger than the sum of the components. The impact on real GDP would be 4 percent after five years and 12 percent in the long term (Figure 7.6).<sup>6</sup> Product market reforms would strongly boost consumption even as labor market and tax reforms act as a drag, especially in the short term. Employment would increase in both the medium and long terms, a reflection of the impact of labor market and tax reforms. Real wages would still be higher, despite downward pressure from

<sup>6</sup> These results differ from those reported in IMF (2013a, 2013b) because these simulations include fiscal reforms, assume a larger gap to close through product market reforms, and use more updated data and a different model.

**Figure 7.6 Benchmark Scenario**

the labor market reforms. The unit labor cost would decline, and a strong labor productivity increase, driven by product market reforms, would dominate.

### **Reform Coordination, Spillovers, and Intra–Euro Area Rebalancing**

Synergies would come into play from the simultaneous implementation of reforms in the core and the periphery. Implementing the benchmark reform scenario simultaneously in both regions would provide slightly larger gains than the added effect from reform packages implemented in each region in isolation (Table 7.3). Spillovers would be greater from the core to the periphery of the euro area than from the periphery to the core (Tables 7.4 and 7.5). If the periphery reformed alone, the core would gain  $\frac{1}{4}$  percent of real GDP. However, if the core reformed alone, the periphery would gain  $\frac{1}{2}$  percent of real GDP in the short term and  $1\frac{1}{2}$  percent of real GDP in the long term. First, the periphery exports more to the core than it imports, so if the core reforms by itself, the export increase by the periphery (and the positive effects on periphery real GDP) would

be greater than vice versa. Second, the model assumes that productivity improvements would spill over from the more advanced core countries.<sup>7</sup> Finally, the model assumes that monetary policy would remain accommodative in the short term, leading to higher inflation, thereby reducing real interest rates and boosting real GDP.

Reforms in the periphery would boost competitiveness and help rebalancing, even if the core reforms simultaneously. The spillovers from increased productivity of one region to the other would lead to extra expansion of their productive capacities, further driving up both employment and real wages (Table 7.6). Consequently, greater gains occur in labor productivity under simultaneous reform. However, the decline in the real effective exchange rate and unit labor costs would not be as great in the long term under simultaneous reform—both regions are producing goods more cheaply, and one region could not have achieved the competitive advantage that would result if only one region had reformed. Nonetheless, in the simultaneous reform scenario, rebalancing between the core and the periphery would still occur because the periphery would depreciate against the core (albeit not as strongly) because it has a more comprehensive package of reforms, which would be reinforced by larger productivity spillovers from the core (larger than the effect of its own productivity reforms spilling over to the core).

In addition, simultaneous reform in both the core and the periphery would have a long-term positive, but modest, impact on the global economy. The rest of world's real GDP would be about ½ percent above baseline in the long term (Table 7.7). The short-term spillovers would be negative for the rest of the world because the euro would depreciate. However, in the long term, spillovers from the euro area would be larger, emanating from higher productivity levels and a positive income effect in the euro area that would increase the euro area demand for goods from the rest of world. Also, because the euro area debt-to-GDP ratio would decline by 20 percentage points from pension and unemployment reforms in the long term, a larger pool of global savings would be available for investment, thereby driving down the global real interest rate. This lower interest rate would lower the global cost of capital and stimulate the global economy.

### Reform Implementation: Macroeconomic and Policy Environment

Potential gains from structural reforms could be sizable, but various macroeconomic and policy factors may affect their actual impact. This section focuses on three such factors:

- Policy credibility;
- Short-term price stickiness; and
- Initial demand conditions.

---

<sup>7</sup> Cross-country spillovers solely from trade linkages are relatively weak (as is the case in dynamic stochastic general equilibrium models in general), but technology and positive productivity spillovers can be important. We explicitly model a link in which productivity spills over from countries that reform to their closest trading partners based on work in Coe and Helpman (1995), Coe, Helpman, and Hoffmaister (1997), and Lumenga-Neso, Olarreaga, and Schiff (2005).

### The Role of Policy Credibility

The speed at which gains could be realized in the euro area is affected by the degree of credibility of the announced reform packages. In the benchmark scenario, households and firms believe only gradually that the reform package will be fully implemented beyond the reforms carried out in the current year. If instead they immediately believed in implementation of the reform package as announced, the increase in real GDP would be faster (Figure 7.7). The households that can save would embrace the future increase in wealth from the promised continuation of the reform early on and would immediately increase their consumption.

The labor market would also behave very differently. If there were full policy credibility, households and firms would foresee the potential for future production, and more labor would be used in the short term, until such time that firms could invest enough to generate a higher capital stock to permanently increase their productive capacity. In the benchmark case, the labor response would be much weaker because no long-term changes in labor demand would be perceived initially. After the sixth year, labor would pick up as the full future benefits come to be understood, and firms still would not have enough capital in place. So, if households and firms believe in the future path of reform, employment would peak early (in year 3) and then decline. Otherwise, employment would build gradually and would peak at a lower level (in year 6), but the peak would be sustained for a longer time. Once households and firms fully believe in the reform package, the results are the same as under the case in which they believe in the reform package from the start.

**Figure 7.7 The Role of Credibility in the Benchmark Scenario**

 Note: L.R. is the long run (2060).

### The Role of Short-Term Price Stickiness

Competition-enhancing structural reforms reduce price and wage markups, but short-term costs of adjustment matter as well. Changes in markups would have short- and long-term effects on macroeconomic aggregates, but they do not directly affect the short-term dynamics of prices. In the short term, prices are driven by nominal adjustment costs present in the economy. In the benchmark scenario, changes in prices from any given shock take roughly 50 percent longer to work their way through the economy than in the most flexible major region, the United States. However, as markets become more competitive, the speed of price adjustment can be expected to increase.

An assumption of more flexible prices in the euro area does not materially affect the results. The analysis assumes that the monetary policy rule in the euro area has the same level of aggressiveness as in the United States, given that this property is related to the short-term stickiness of prices. The benchmark reform scenario is tested under this different assumption, without considering the transition path from higher to lower price stickiness. The outcomes can be read as the upper bound of the effects on the transition dynamics from their impact on product and labor market reforms (Table 7.8). The long-term results remain unchanged, while there are slightly greater gains in the short term because firms and households more rapidly adjust their prices and wages to reflect the future changes in the economy, thereby incurring lower costs from short-term inertia.

**Table 7.8. The Role of Price Stickiness in the Short Term, Decomposition of Real GDP***(Percent deviation from baseline)*

## The Role of Demand Conditions

Weak demand and excess capacity conditions may limit the short-term output response to reforms. In particular, balance sheet concerns and low confidence encumber private sector decisions, thereby weakening demand and possibly hindering the effectiveness of supply-side reforms. For example, relaxing employment protection may not stimulate hiring in the short term, but increase unemployment. Similarly, reducing unemployment insurance or increasing the retirement age would lower disposable income if those induced to seek work cannot find jobs. Overall, there are considerable uncertainties about the immediate effects of implementing structural reforms during a recession.

An illustration estimates the worst-case impact of weak demand conditions by assuming that firms would not hire any additional workers. No hiring would occur despite the increase in labor supply that comes from labor market reforms such as increased child care, ALMP, and reduced unemployment insurance benefits. In reality, labor demand would most likely increase in the long term, although the negative short-term effects could occur. Demand for other factors of production would also be lower compared with the benchmark scenario. To discuss the lower bound effectively, the analysis only considers the case in which reforms are immediately and fully believed in by households and firms, and compares this to the version of the benchmark scenario implemented in the same manner (as shown in the left panel of Figure 7.7).

**Figure 7.8 Impact of Weaker Initial Demand Conditions**

Sources: Global Integrated Monetary and Fiscal Model simulations using OECD and IMF staff estimates  
 Note: L.R. is the long run (2060).

The short-term impacts on real GDP would be substantial because real GDP would fall in the first year instead of increasing. The shortfall could be as high as 4 percent of real GDP (Figure 7.8), driven primarily by labor market reforms. Real wages would decline relative to the benchmark because the increase in labor supply would allow firms to slash wages, and the marginal product of labor would decline.

Product market and tax reforms would still be fairly effective in the medium term under restricted labor demand. Both sets of reforms act on both factors of production, capital and labor. So although employment may not increase in this scenario, capital will increase by almost enough to overcome the weakness in labor demand. On the demand side, labor income, on balance, would be lower than in the benchmark scenario, although households that save would experience higher wealth from the notable increase in the capital stock (which is an increase in the equity of firms). Moreover, the depreciation in the real effective exchange rate would be greater because all goods would be even cheaper, not only from the decrease in markups and increase in productivity from the reforms, but also from the long-term decline in real wages in response to rigid labor demand.

## Concluding Remarks

The analysis illustrates that structural reforms in the euro area can increase its real GDP markedly, though it may take time for their full potential to be achieved. Structural reforms are critical to improving the long-term capacity of economies to grow through both more intensive use of resources and higher productivity. Weak demand conditions may dampen the already small short-term impact. The long-term gains are largest in the periphery countries, where growth is most needed. Reforms would also boost euro area competitiveness. The largest gains for euro area countries could come from product market reforms; labor market reforms could have a positive but more modest impact on real GDP. Simultaneous implementation of product and labor market reforms would generate an additional GDP payoff.

The author is particularly grateful to Andrew Burns, Jørgen Elmeskov, Michael P. Feiner, John P. Martin and Jon Nicolaisen for their many comments and suggestions on earlier drafts of this paper. Thanks also go to Sveinbjörn Blöndal, Michael Daly and Nick Vanston as well as a number of other OECD colleagues. Catherine Chapuis-Grabiner, Martine Levasseur and Jean-Philippe Spector provided valuable statistical assistance, while secretarial assistance was provided by Sandra Raymond and Brenda Livsey-Coates. Needless to say, the responsibility for remaining errors or omissions rests with the author.

---

## INTRODUCTION

Unemployment varies greatly across OECD countries and over time. During the past two decades, it was relatively trendless, albeit subject to cyclical fluctuations, in Japan and the United States, while it rose dramatically in many European countries. In the latter, unemployment rates also showed a high persistence. After rising during cyclical downturns, they tended to remain at (or close to) new higher levels after subsequent recoveries, suggesting that most of these increases were translated into higher "equilibrium" unemployment. For example, in EU countries, the rate of unemployment consistent with stable wage inflation (NAWRU) rose, more or less steadily, from less than 5 per cent in the mid-1970s to almost 10 percent in the early 1990s, while in the United States, the rise in the 1970s was partially reversed thereafter and the NAWRU is currently around 5 per cent.

High unemployment levels in Europe were accompanied by a growing incidence of long-term unemployment (LTU), from less than one-third of total unemployment in the late 1970s to almost 45 per cent in the early 1990s. In contrast, the incidence of LTU has remained relatively constant in the United States and Japan at about 10 and 15-20 per cent, respectively. There are also major differences in participation rates. The major European countries often have more than 40 per cent of their working-age population inactive (i.e. unemployed and not in the labour force). This compares with only a quarter in Japan and less than one-third in North America, Oceania and the Nordic countries.

As stressed in the OECD *Jobs Study* (1994b), an ensemble of factors – macroeconomic policies, trade and foreign direct investment, technology and innovation – interact with labour and product market policies and institutions, such as education and training, wage and price determination processes and welfare benefits, to determine the levels and dynamic behaviour of employment and unemployment rates across countries. The OECD work on the *Jobs Study* indicates that a number of these policy and institutional factors have played an important role in determining unemployment rates. This paper tries to assess the role of some of these factors.

The empirical analysis is conducted from two perspectives. Firstly, it examines the role that different policy and institutional settings have played in determining the marked differences in the level of structural or "equilibrium" unemployment

across the OECD countries during the past decade. Secondly, it looks at the role of these same policy and institutional factors in determining the persistence of unemployment

The results encompass most of the previous cross-country studies comparing labour market performance and, in particular, those of Layard *et al* (1991) and Bean and Symons (1989). They also offer new insights as to how policies and the mechanisms of wage determination may affect aggregate unemployment and other measures of labour market slack, such as youth and long-term unemployment rates and non-employment rates.<sup>2</sup> The use of these other measures of labour market slack gives a better understanding of the mechanisms through which distortions in the labour market affect unemployment and gives a better identification of potential beneficiaries of reforms

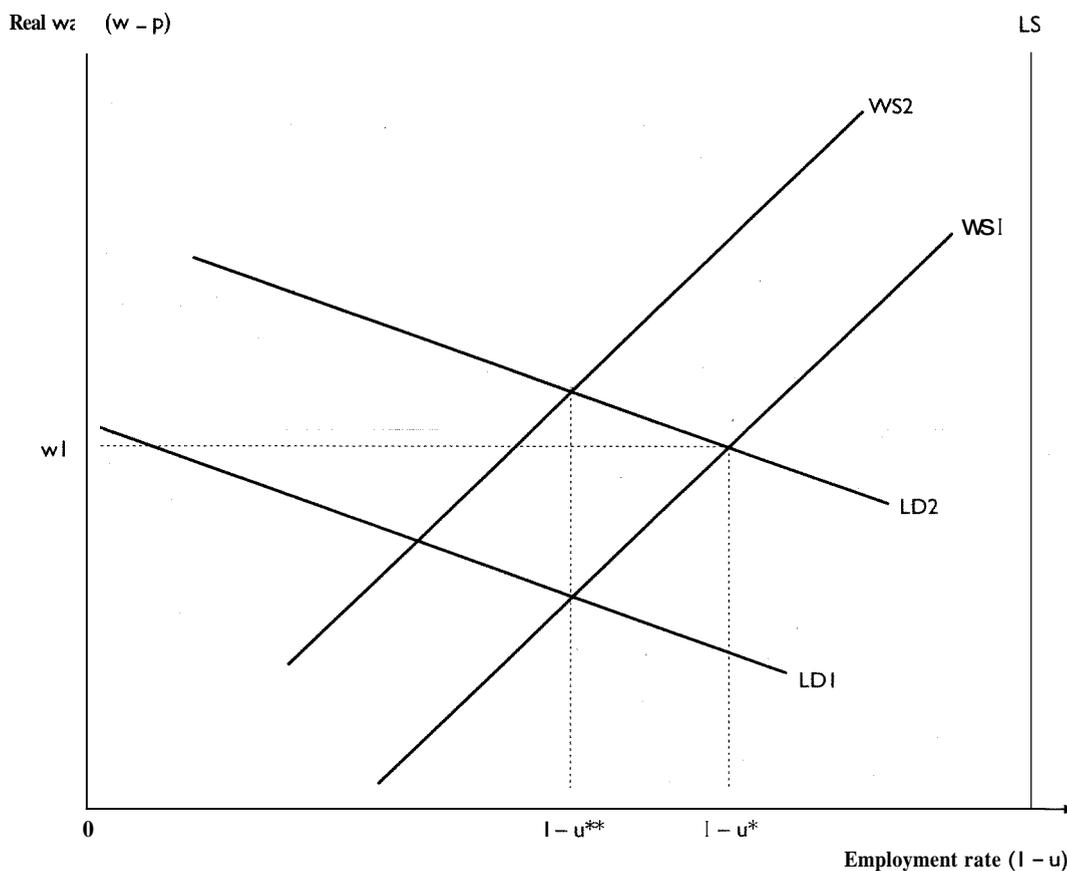

The broad empirical conclusions suggest that policy variables and the institutional mechanisms of wage determination do matter for the **level** of structural unemployment as well as for the **speed of labour market adjustment** in the OECD countries. In particular, overly generous unemployment benefits and stringent employment protection regulations contribute to raise equilibrium unemployment and reduce the speed of labour market adjustment after an exogenous shock. The different facets of countries' wage bargaining systems interact strongly. Insofar as its effect can be isolated, the paper suggests that greater co-ordination amongst the social partners is always beneficial to labour market performance, regardless of the degree of unionisation. The relationship between the degree of centralisation of wage bargaining and unemployment is more complex. In general, the results support the *hump-shaped* hypothesis whereby both highly centralised and fully decentralised wage bargaining systems offer the best results.

The paper is divided into four sections. The first section presents briefly the theoretical framework underlying the study and discusses some methodological issues related to the empirical analysis. The second section outlines the policy and institutional variables used, while the empirical results are discussed in the third section. The final section summarises the main findings.

## THE THEORETICAL FRAMEWORK AND THE ESTIMATION PROCEDURE

### The theoretical framework

Figure 1 presents a simple model of equilibrium in the labour market. The model assumes an economy of imperfectly competitive profit-maximising firms, each facing exogenously determined product market conditions and predetermined capital and technology (see Layard *et al.*, 1991 and Bean, 1994). Moreover, wages are bargained between workers and firms, the latter deciding on the level of employment, output and prices once a wage agreement has been reached ("right-to-manage" model). Ignoring for simplicity labour force growth and trend productivity

Figure 1. *Labour demand and wage-setting schedules*

Source: OECD.

effects, this simple model can be summarised on the basis of the following relationships:

– **labour demand schedule (LD):**

$$n = -\alpha(w - p) - \beta Z_n - w^u \quad \alpha > 0 \quad [1]$$

– where  $n$ ,  $w$  and  $p$  are respectively the logarithms of employment, wages (including payroll taxes) and prices,  $Z_n$  is a vector of variables influencing labour demand, which may include a mark-up of prices over marginal costs, and  $w^u$  is unanticipated wages which account for expectational errors.

- **wage-setting schedule (WS):** real wages are assumed to be a decreasing function of unemployment and an increasing function of wage push factors ( $Z_w$ ),<sup>3</sup> allowing for unanticipated price changes  $p^u$ . Thus

$$w - p = \delta_1 Z_w - \gamma_1 u - p^u \quad \delta_1 \geq 0; \gamma_1 \geq 0 \quad [2]$$

The  $Z_w$  vector should include factors such as the generosity of unemployment benefits, the relative strength of unions and the overall features of the wage bargaining process, as well as the tax wedge on the use of labour and the degree of mismatch between the skills and geographical location of job seekers on the one hand and those of the unfilled job vacancies, on the other. The parameter  $\gamma_1$  measures the impact of unemployment on wage setting and is likely to be affected by some of the factors included in  $Z_w$ .

- **labour supply (LS)** is assumed, for simplicity, inelastic to wages and a function of factors affecting participation decisions ( $Z_p$ ), including some of the elements of wage push ( $Z$ )

$$l = \delta_2 Z_p \quad \delta_2 > 0 \quad [3]$$

where  $l$  is the logarithm of the labour force

Since  $l - n \equiv u$ , equation [1] can be re-written as

$$l - u \equiv -\alpha(w - p) - \beta Z_n - w^u \quad [4]$$

The structural unemployment rate  $u^*$  is the value that solves equations [2], [3] and [4] when price and wage expectations are met (*i.e.*  $p^u = w^u = 0$ )

$$u^* = \frac{\alpha \delta_1 Z_w}{1 + \alpha \gamma_1} + \frac{\delta_2 Z_p + \beta Z_n}{1 + \alpha \gamma_1} \quad [5]$$

which is illustrated in Figure 1 at the intersection of the labour demand and wage-setting curves in the  $(1 - u, w - p)$  space

From equation [5] any factor that exogenously increases wage-push ( $Z$ ) or labour demand shifts ( $Z$ ) (e.g. an increase in the mark-up) would raise equilibrium unemployment. In the first case, the raise in equilibrium unemployment will be accompanied by an increase in real wages, while in the second case, it will be accompanied by a fall in real wages. As an illustration, a leftward shift in the WS schedule (from WS1 to WS2) could be the result of an increase in workers' power in wage bargaining. By the same token, a leftward shift (from LDI to LD2) of the labour demand schedule may result from reduced competition in the product market which would lead to persistently higher price mark-ups. In both cases, the equilibrium unemployment rate shifts to a higher level ( $u^{**}$  in Figure 1), and this increase would not be reversed by endogenous forces<sup>4</sup>

The policy and institutional factors which enter the wage-setting schedule [2] may influence not only the long-run equilibrium unemployment, but also the speed with which the labour market reacts to an exogenous shock. In the context of the bargaining model set up by equations [1] and [2], persistence mechanisms could be brought in by allowing wages to be a function of the change in unemployment as well as the level of unemployment. The rationale for this specification of the wage-setting schedule can be found in the behaviour of both firms and workers. High hiring and firing costs may introduce inertia in the firms' employment decisions. On the basis of the "insider-outsider" hypothesis (see below), it could also be argued that real wages may be more responsive to the threat of large-scale redundancy and rising unemployment than to the level of unemployment *per se*. Likewise, in the context of rising unemployment, the proportion of short-term unemployed (*i.e.* those most likely to compete directly with the employed) generally increases and this could put more downward pressure on wages than a stable level of unemployment

The introduction of the change in unemployment in the process of wage determination yields a new wage-setting schedule [2'] and allows for the definition of a short-term equilibrium unemployment ( $su^*$ ) as opposed to the long-term equilibrium defined by [5]

$$w - p = \delta_1 Z_w - \gamma_1 u - \gamma_2 \Delta u - p^u \quad \gamma_2 \geq 0 \quad [2']$$

The parameter  $\gamma_2$  is likely to be affected by labour market policies, via their impact on the effectiveness of job search and on its intensity, as well as by institutional factors influencing the insiders' power in wage bargaining.

The long-run steady-state equilibrium  $u^*$  has not changed as  $\Delta u = 0$  in equilibrium. However, in the short term, structural unemployment depends upon  $u_{t-1}$ . In particular,

$$su_t^* = \frac{-\alpha\delta_1 Z_w + \delta_2 Z_p + \beta Z_n}{1 + \alpha\gamma_1 + \alpha\gamma_2} + \frac{u_{t-1}}{1 + \frac{\alpha\gamma_1}{\alpha\gamma_2}} \quad [6]$$

or

$$su_t = \lambda u_{t-1} + (1 - \lambda)u^* \quad [6']$$

and the adjustment speed

$$(1 - \lambda) = \frac{1 + \alpha\gamma_1}{1 + \alpha\gamma_1 + \alpha\gamma_2} \quad [7]$$

The adjustment speed depends upon the flexibility of wages to the level ( $\gamma_1$ ) and changes ( $\gamma_2$ ) in unemployment. When the estimated coefficient  $(1 - \lambda)$  lies

between 0 and 1, there is said to be partial hysteresis or slow adjustment (Elmeskov and MacFarlan, 1993), while a coefficient equal to 0 points to full hysteresis.

### Estimation procedure

Equations [5] and [6] offer the basic framework for the analysis of cross-country variations of unemployment. In particular, two questions should be addressed. How do labour market policies and institutional factors affect the equilibrium unemployment rate  $u^*$ ? Moreover, how do these factors influence the speed of adjustment  $(1 - \lambda)$ ? To make the best use of the information available, these two questions are treated in turn.

To address the first question, we estimated the relative importance of policy and institutional variables in determining the wide disparities in structural unemployment and the potential effects of reforms, using a **static model** over the 1983-1993 period. The period corresponds, more or less, to a full business cycle, over which structural unemployment has remained relatively stable in most OECD countries, at least compared with the dramatic increases of the 1970s and early 1980s. This is also the period for which most of the information is available on several institutional features of the labour market and on labour market policies.

Since the policy and institutional factors are likely to have different impacts on different groups of the unemployed population and on participation decisions, four different measures of labour utilisation were used as the dependent variable: i) the total unemployment rate; ii) the youth unemployment rate, iii) the long-term unemployment rate; iv) and the non-employment rate. Comparisons between the results of the four different equations may offer a more complete picture of the effects of labour market policies and institutional factors on the labour market and help the identification of potential beneficiaries of reforms. Nevertheless, the use of the same specification for all four measures implies that a portion of cross-country variation remains unexplained as certain specific factors – such as minimum wages in the youth equations – are omitted from the analysis.

Using cross-country and time-series data and adding an explanatory variable to account for the effects of aggregate demand fluctuations over the cycle, the actual unemployment rate and the other three measures of labour market slack can be modelled by a reduced-form equation with the following structure

$$u_{it} = \mu_0 + \mu_i + \sum_k \beta_k x_{kit} + \sum_j \tau_j z_{ji} + \phi g_{it} + v_{it} \quad [8]$$

where  $i$  indexes countries,  $t$  the years,  $u_{it}$  is the unemployment rate (or one of the other measures of labour market slack),  $x_{it}$  is a  $k \times 1$  vector of time-varying explanatory variables,  $z_i$  is a  $j \times 1$  vector of variables which vary across countries but not over time,<sup>5</sup>  $\mu_0$  is a constant,  $\mu_i$  is the country-specific effect not accounted for by the available explanatory variables and  $v_{it}$  is the usual error term. Both  $x_{it}$  and  $z_i$

vectors consist of policy and institutional variables deemed likely to affect labour market conditions, while  $g_t$ , is the output gap (see below) included to account for changes in the business cycle

To shed some light on the speed of labour market adjustment, a **dynamic** version of the unemployment rate equation is also estimated over the 1970-1993 period, which encompasses the upsurge in unemployment after the two oil shocks. In this case, actual unemployment rate ( $u_{it}$ ) is expressed as the sum of the short-term equilibrium rate ( $su_{it}^*$ ) – which, from equation [6], is a function of lagged actual unemployment rate and the long-run steady-state equilibrium rate ( $u_i^*$ ) – plus a cyclical component which is identified using the output gap variable. From equation [7] the coefficient on lagged unemployment rate ( $\lambda$ ) mainly depends on the parameters  $\gamma_1$  and  $\gamma_2$  which, in turn, are functions of the labour market and institutional factors included in the  $\mathbf{x}_{it}$  and  $\mathbf{z}_i$  vectors. The long-run steady-state equilibrium unemployment ( $u_i^*$ ) is proxied by country-specific effects  $\mu_i$  and the few time-varying explanatory variables ( $\mathbf{x}_{it}$ ) for which long time-series are available<sup>6</sup>. Thus, the reduced-form unemployment equation can be written as

$$u_{it} = \mu_i + \left[ \mu_0 + \sum_k \delta_k x_{kit-1} + \sum_j \phi_j z_{ji} \right] u_{it-1} + \sum_k \beta_k x_{kit} + \phi g_{it} + v_{it} \quad [9]$$

where the notation is the same as for equation [8]<sup>7</sup>

## EXPLANATORY VARIABLES

### Cyclical factors

At any point in time, countries can differ in their relative position in the business cycle and in the amplitude of the cycle around the long-run trend. These differences are likely to affect the size and dynamic behaviour of the cyclical component of actual unemployment rates. To account for these factors, we used a measure of the output gap (GAP) defined as the percentage difference between actual and the long-run trend output, the latter obtained using a GDP smoothing approach based on the Hodrick-Prescott filter<sup>8</sup>. It should be stressed that, like any other index of the cycle, the output gap measure is not an exogenous variable, although it is reasonable to assume that it is economically predetermined (in the sense that changes in the cycle drive changes in employment and unemployment and not vice versa)

### Policy variables

#### *Active labour market policies*

Active labour market policies (ALMP) encompass different measures, including

and different forms of subsidised employment (OECD, 1993) These policies may reduce aggregate unemployment by shifting rightward the WS schedule of Figure 1<sup>9</sup> For example, raising the search effectiveness of job seekers could lead to greater efficiency in job matching and reduced real wage pressure,<sup>10</sup> which in turn would reduce the duration of Unemployment spells and raise employment (Layard and Nickell, 1986). Moreover, the enhanced qualifications of participants in training schemes are likely to raise their productivity once at work (OECD, 1993). On the other hand, the existence of generous active programmes may be taken by unions or employed workers as a signal of accommodation, which will raise wage pressure, shifting the WS schedule leftward and contributing to longer duration of unemployment spells and higher overall unemployment rates.

The government's commitment to active labour market policy is proxied by expenditure on active measures per unemployed person relative to output per capita (ALMPU) as in Layard *et al* (1991)<sup>11</sup> The per-capita measure takes into account a potential non-linearity in the relationship between active programmes and unemployment<sup>12</sup> However, the introduction of ALMPU in the unemployment equation is likely to lead to a simultaneity bias in the estimated parameters.<sup>13</sup> This would occur if governments react to changes in unemployment – or other signals of labour market conditions – with changes in total spending on ALMPs, which makes it difficult to disentangle the effect of active policy on the labour market We tried to minimise this problem by entering ALMPU as a fixed effect, using the average spending over the entire period for which data are available (1985-1993)

However, a further difficulty in determining the impact of ALMPs on unemployment arises if (some) programme participants are simply excluded from the count of unemployed job seekers although they are looking for work Under these circumstances, an obvious effect of increasing expenditures on – and participation in – ALMPs is to reduce “measured” unemployment without any change in “actual” unemployment Indeed, evidence indicates that in many OECD countries there is a positive correlation between unemployment dynamics and participation in active programmes<sup>14</sup> As unemployment rises, participation in ALMP increases, which suggests that the absolute number of “hidden” unemployed workers may increase when unemployment is high. For these reasons, when interpreting the impact of ALMP on measured unemployment, it is necessary to keep in mind this possible bias

### ***Unemployment benefits***

A large number of both macro and micro studies<sup>15</sup> (including the OECD *Jobs Study*) suggest that the level and especially the duration of unemployment benefits are likely to affect overall unemployment and its persistence Unemployment benefits may be expected to raise beneficiaries' reservation wages, thereby reducing

their search efforts and their willingness to accept job offers (*i.e.* leading to a leftward shift in the WS schedule) Moreover, generous benefits may reduce the insiders' (employed individuals) willingness to restrain their wage claims in the face of unemployment pressure (*i.e.* a flatter WS schedule in Figure 1). On the other hand, unemployment benefits act as a subsidy to job search, helping to overcome an asymmetric-information externality and contributing to better job matching and, thus, lower unemployment (via a rightward shift in WS)

The full complexity of the unemployment benefit system (UB)<sup>16</sup> is approximated in this study by a summary index of benefit entitlements derived from the OECD *lobs Study* (Chapter 8) The UB index is based on a simple average of net (after-tax) replacement rates for individuals with different durations of the unemployment spell, different levels of earnings and different family situations.<sup>17</sup> In the overall unemployment equations and in the non-employment equations, the index includes all duration categories (1-5 years), while in the LTU equations the summary index (UB2) includes replacement rates for durations longer than 12 months and in the youth unemployment equations the index (UB3) includes only replacement rates for the first 12 months<sup>18</sup> These measures partially overcome the simplification involved in representing the unemployment compensation system by a crude replacement rate and/or by a measure of maximum duration (Atkinson and Micklewright, 1991). Nevertheless, since these indices summarise different situations, they are inevitably somewhat arbitrary and do not differentiate the role of each individual component of the UB system in explaining unemployment (Martin, 1996).

### ***Employment protection legislation (EPL)***

In many countries, especially in Europe, the freedom of firms to hire and fire workers is limited by a variety of "employment protection" regulations.<sup>19</sup> As stressed in the OECD *lobs Study*, these regulations, if binding, are likely to operate in two directions. On the one hand, they may reduce arbitrary dismissals; lower contracting costs by setting general rules and standards, encourage on-the-job training and human capital formation (thereby raising productivity and earnings of "insiders") and, finally, provide for early warnings to allow workers to engage in job search prior to being laid off On the other hand, if firms feel that these regulations oblige them to retain workers who are no longer needed, they may become cautious in hiring and more selective in the choice of applicants, to the particular detriment of disadvantaged workers (often low-skilled, long-term unemployed and youth) Moreover, EPL may affect the structure of employment by indirectly promoting atypical (*i.e.* part-time and temporary) labour contracts which offer firms the workforce flexibility they would not have otherwise enjoyed, but which may act to consolidate insider power (Bentolila and Dolado, 1994)

As a proxy for the strictness of employment protection regulations, this paper uses the average of two indices measuring the strictness of EPL rules for regular and fixed-term contracts (see OECD *lobs* Study; and Grubb and Wells, 1993). While a relatively crude measure, this index offers a more complete picture of the different factors affecting decisions to hire and fire workers than other measures used in the literature, such as those based on employer surveys alone, as in (Emerson, 1988).<sup>20</sup>

### ***Non-wage labour costs***

Taxes on labour use have often been identified as a factor shaping the wage formation process and factor utilisation. A tax wedge on the use of labour can be defined as the difference between gross labour costs to employers and the consumption wage (net of direct and indirect taxes) paid to employees. This difference is affected by several elements – which vary a great deal across countries – including employees' and employers' social security contributions, income taxes and indirect taxes.

The macroeconomic impact of a change in the tax wedge depends on the reactions of both firms and workers. For example, in a perfectly competitive environment, an increase in payroll taxes will have no long-run effects on unemployment, insofar as wages will adjust to whatever level is needed to clear the market. However, if markets are imperfect and workers are able to resist offsetting wage cuts, an increase in these taxes may result in lower employment (*i.e.* a leftward shift in the LD schedule)<sup>21</sup> The occurrence of the latter depends, among other things, on the relative bargaining strengths of trade unions and employers (in the  $Z_w$  vector of {2}), and on firms' ability to pay wages in excess of market-clearing levels, which may also depend upon the degree of competition in the product market (in the  $Z_n$  vector of {1}). Moreover, an increase in taxes may be particularly detrimental to the employment prospects of certain categories of workers, such as low-paid workers, but not for others. For example, in the case of low-paid workers, employers may not be able to reduce wages to compensate for an increase in social security contributions if binding wage floors are established by statutory minimum wages, negotiated wage floors or high reservation wages induced by social welfare provisions.

Given data availability, the tax wedge indicator (TWEDGE) used here is based on average tax rates for average production workers, including employers' and employees' social security contribution rates, personal income tax rates and, finally, indirect tax rates (See Annex A for details) However, a marginal tax wedge is also considered using a smaller sample of countries to test whether the impact on unemployment differs

## Institutional factors

### *Unions and the wage bargaining process*

The wage bargaining process can play a crucial role in determining labour-market conditions and the speed of adjustment. For example, in the wage bargaining model set up in the previous section, wages may remain above market-clearing levels because the institutional system gives employees market power, thereby raising wages (*i.e.* a leftward shift in the WS schedule of Figure 1). However, these effects may be moderated, or even reversed, in contexts of fully centralised wage bargaining or when there is a high level of co-ordination among employers and among unions.

One common indicator of the character of industrial relations in a number of “insider-outsider models” is union density (the proportion of workers who are members of trade unions). Yet, a high degree of unionisation is not *per se* sufficient evidence of workers’ market power. In many countries, the administrative extension of wage agreements means that workers who are not union members are often covered by the terms and conditions of union contracts. By the same token, high union power in one sector can lead to spillover effects in non-union sectors (Blanchard and Kiyotaki, 1987).

In an effort to accommodate these elements, a measure of union density is complemented by two alternative indicators of the nature of the wage formation process: *i)* the degree of centralisation of wage bargaining, and *ii)* a measure of the degree of co-ordination among employers and among employees in the wage bargaining process.

A highly centralised wage bargaining system may allow the economy to respond in a more consistent way to adverse shocks than decentralised systems in which different groups/sectors/companies negotiate separately over wages (Tarantelli, 1986; Bruno and Sachs, 1985). However, Calmfors and Driffill (1988) have stressed that the relationship between centralisation of wage bargaining and wage outcomes is not monotonic, but rather hump-shaped.<sup>22</sup> The hump-shaped hypothesis suggests that both highly centralised (co-operative) bargaining structures – such as those in Austria and the Nordic countries – and fully decentralised (competitive) structures (United States) offer the best results.<sup>23</sup> In an intermediate (*ie* neither highly centralised nor highly decentralised) system – as in many EU countries – bargaining units are strong enough to generate dis-employment effects, but at the same time, each unit is vulnerable to other units’ wage strategies without being able to influence these strategies (a sort of “prisoner’s dilemma”).

Co-ordination refers to the extent to which decisions taken by trade unions and employers’ associations at the different bargaining levels (national, sectoral or company) are concerted so as to foster a mutually beneficial strategy.

The different equations estimated in this paper include the degree of unionisation together with either the indices of centralisation of wage bargaining or co-ordination as separate explanatory variables<sup>24</sup> In the first case, the country ranking of the relative degree of centralisation suggested by Calmfors and Driffill (CLWB) and its square (CLWB2) are included to account for the hump-shaped hypothesis In the second case, the Layard *et al* (1991) indices of employers' co-ordination (ECOOR) and employees' co-ordination (UCOOR) are used, or, alternatively, a summary measure of overall co-ordination (COOR), which sums the ECOOR and UCOOR indices. In the unemployment and non-employment equations, one would expect: a positive sign on CLWB and a negative sign on its square CLWB2 (the measure of corporatism is based on rankings in which lower numbers refer to higher levels of centralisation); a negative sign for both the index of employers' co-ordination and the index of unions' co-ordination

### ***Exposure to trade as a proxy for product market competition***

The lack of competition in the product market may have direct as well as indirect effects on the labour market In the presence of market power, profit-maximising firms will set prices above the marginal cost of production and consequently labour demand will be lower than otherwise would have been the case Moreover, employers may share product-market rents with their employees (insiders) (Geroski *et al.*, 1996) thereby raising wages above competitive levels and reducing employment levels. The combination of wage premia and low employment in non-competitive sectors may have spillover effects on other sectors of the economy in different ways, As stressed above, the automatic extension of wage agreements may also distort the balance between costs and productivity in more competitive sectors; the unemployed may prolong their search in the hope of acceding to highly paid jobs; and, finally, dismissed workers from "high-wage" firms may have very high reservation wages, especially in countries with earning-related unemployment benefits (OECD *Jobs Study*, Chapter 5)

Unfortunately no direct measure is available on the overall degree of product market competition in OECD countries. Indirect information can, however, be gathered from trade data In particular, measures of openness to foreign trade may shed some light on the degree of competitiveness to which domestic firms are exposed As a proxy for the pervasiveness of trade restrictions, a summary index was calculated on the basis of sectoral data on tariff rates and the frequency of non-tariff barriers (see Annex B for details) The larger the trade restrictions index (TRESTR), the more protected the domestic economy is However, insofar as countries differ a great deal in the relative importance of trade in national income (not least because of their size), the TRESTR index by itself may not necessarily offer an accurate picture of the effects of different trade policies on competition and resource allocation For example, two countries starting with the same levels of trade restrictions

but having different overall degrees of exposure to foreign trade may experience different output and employment effects by implementing the same trade reform package. Thus, an additional variable was introduced (INTER) which measures the interaction between TRESTR and an index of exposure to foreign competition (COMP). The latter combines an index of export intensity and an index of import penetration (see Annex A for details).

## Other factors

### *Real interest rates*

Several recent studies suggest that the significant increases in real interest rates during the 1980s, driven by increases in the public debt of many OECD countries, might have been among the driving factors behind the upsurge in unemployment, at least in countries where persistence mechanisms are at work. In particular, Phelps (1992, 1994) put forward several models in which real interest rates may affect unemployment. For example, in his “customer market” model of pricing, Phelps suggests that a reduction in real interest rates increases the incentives to invest in expanding market shares. Thus, the reduction in marginal production costs resulting from a fall in interest rates is likely to be followed by a reduction in price mark-ups which, in turn, should have positive effects on employment. Moreover, in an inter-temporal model, if workers have non-wage income, an increase in the rate of interest may reduce the expected utility of being employed. Along the same lines, Manning (1991) suggested that a higher interest rate – which in his model proxies the discount factor that workers apply to the value of potential future employment – reduces the opportunity cost of being unemployed in the future and makes workers more aggressive in their current wage claims.

Given the highly integrated world capital market, the paper uses a measure of the world real interest rate based on a CDP-weighted average of domestic long-term rates.<sup>25</sup>

### *The terms of trade*

It has also been argued that the deterioration of the terms of trade following the two oil shocks might have affected equilibrium unemployment insofar as it created a wedge between value-added prices and consumer prices.<sup>26</sup> This would then affect unemployment through much the same mechanisms as discussed above for the tax wedge. Since the potential impact depends on each country’s exposure to trade, the terms-of-trade variable (TERMS) was weighted by the average of the COMP index which, as described above, measures the degree of exposure to foreign trade.

## EMPIRICAL RESULTS

### The structural determinants of unemployment

Equation [8] was used to assess the role of policy and institutional factors in determining cross-country variations in structural unemployment. The analysis is based on annual data over the 1983-1993 period for a group of OECD countries (from 15 to 17 countries depending upon data availability under the different specifications)<sup>27</sup> Since the precise structure of the models was not known, Hendry's "general-to-particular" estimation approach was used to maximise the efficiency of estimates while allowing for a parsimonious specification. A sequential approach was used to identify the appropriate estimation technique: each equation was first estimated using OLS and the presence of unobservable country-specific effects was verified by a conventional F-test.<sup>28</sup> When the null hypothesis of cross-country equality of the constant term was rejected at conventional significance levels, error-components models using Feasible Generalised Least Squared (FGLS) were considered. The assumption that country-specific effects are random was tested using Honda's (1985) test. If the null hypothesis of non-randomness of country-specific effects was rejected, Hausman's (1978) orthogonal test was used to test for the correlation between the random country-specific effects and the other regressors, as suggested by Hausman and Taylor (1981)<sup>29</sup>

### *Regression results*

Table 1 presents the results of the reduced-form regressions on the total unemployment rate. Tables 2 to 4 present the results for youth unemployment rates, LTU rates and non-employment rates, respectively. The statistical tests discussed above are reported at the bottom of each table. Two basic specifications are used for the wage bargaining system: one with the two co-ordination variables (COOR) (see columns 1 to 7), and another with CLWB and its square replacing COOR (columns 8 to 10). In both cases, union density (UDENS) enters as well. Columns 3 to 5 report estimates incorporating the tax wedge, the terms of trade and the real interest rate, respectively. However, these variables have been omitted in the following steps if their coefficients were not statistically significant. The number of observations used in each equation and the number of countries included in the panel are reported at the bottom of each table.<sup>30</sup>

As expected, the F-tests reject strongly the hypothesis of no country-specific effects in all equations. Moreover, in all equations, the hypothesis of randomness of the country-specific effects cannot be rejected by the Honda test at standard statistical levels. Finally, the Hausman tests suggest possible problems of specification in only a few equations, at the 1 per cent critical level. In these cases, the value of the Hausman test is reported in bold.<sup>31</sup>

Source See Annex A

Drawing from the results of a detailed diagnostic analysis (Box 1 and Annex C), the estimates are based on a panel which excludes data for Finland 1992-1993, Portugal 1983-1984, Italy 1983 and Spain 1993 which appear to influence significantly the estimated parameters. Moreover, two estimates of the ALMPU coefficients are reported in the text, one including Sweden and the other excluding it from the sample as this country strongly influences the estimated parameters of ALMPU.

#### Box 1. The identification of outliers and influential observations

Even after controlling for unobservable country-specific components, any inferences from the empirical results of models using a small panel data set and including qualitative variables should be made with care. Annex C reports the results of regression diagnostics based on the identification of observations which significantly increase the standard error of the regression and/or affect the estimated coefficients. It is worth mentioning at the outset that, after controlling for country-specific effects, there are only a few observations which significantly affect the regression results.

In particular, data for Finland for the early 1990s increase the standard errors of regressions significantly as the explanatory variables are not able to fully account for the rapid increase in Finnish unemployment rates during that period. Moreover, the diagnostic analysis points to the Portuguese data for 1983 – and to a lesser extent 1984 – as potential outliers. This comes as no surprise since unemployment rates dropped from almost 8 per cent in the early 1980s to 4-5 per cent in the 1985-1993 period in Portugal without any major change in the labour market policy and institutional stance (see Blanchard and Jimeno, 1995). Indeed, the indices summarising the labour market institutional settings in the late 1980s classify Portugal as the country with the most rigid employment protection legislation, with wages prevalently set at the sectoral level and with low employers' and workers' coordination in wage bargaining, all features which should be associated with higher unemployment. One possible explanation for this apparent contradiction is that labour market regulations in Portugal may be poorly enforced with little or no effects on wage and employment determination. The diagnostic checking also reveals that both the 1983 observation for Italy and the 1993 observation for Spain have a significant impact on the standard error of the regressions.

The results reported in Annex C also suggest that the inclusion of Sweden in the panel, albeit not affecting the overall performance of the regression, influences significantly the estimated coefficient for ALMPU. In particular, the exclusion of this country implies a stronger (and statistically significant) negative impact of ALMPU on unemployment. This result is not entirely surprisingly as Sweden has been characterised by both extremely high expenditures for active labour market programmes (four times the OECD average) in the 1983-1993 period and by levels of unemployment which, albeit low, are comparable with those of countries which spent much less on ALMPs.

As shown in Table 1, the estimated impacts of **active labour market programmes (ALMPU)** on the unemployment rate are small and in some cases not statistically significant. These results contrast with previous macro-based studies (Layard *et al.*, 1991, Layard and Nickell 1992) but seem consistent with a number of studies based on micro data, which indicate that active programmes have generally a limited impact on worker employability. However, if Sweden is excluded from the panel, the magnitude and statistical significance of the estimated coefficient for ALMPU increases (the estimated coefficient becomes  $-0.23$  in equation 2 in Table 1).

The coefficients in Table 1 make it possible to shed some light on the potential impact of active programmes on regular (*ie* non subsidised) employment – *e.g.* correcting for the influence of ALMP participants on the measurement of unemployment, on the assumption that participants are not counted as employed. Under the hypothesis of a constant labour force, and assuming an ALMP participation rate ( $p$ ) of 3 per cent of the labour force and a measured unemployment rate ( $u$ ) of 8 per cent, the results of Table 1 imply a derivative of measured unemployment rates with respect to ALMP participation rates of about  $-0.45$  in the panel including Sweden, and  $-1.48$  excluding Sweden. In other words, an increase in the number of ALMP participants of 1 percentage point of the labour force reduces measured unemployment by 0.45 to 1.48 percentage points of the labour force. As a consequence, the effect on the rate of regular employment ( $100 - u - p$ ) is either negative ( $-0.55$  percentage points of the labour force) or positive (0.48 percentage points) but still implying significant substitution effects<sup>32</sup>.

High levels of **unemployment benefits** increase structural unemployment significantly (Table 1). The implicit average elasticity of unemployment to the UB index is close to 0.5. These results suggest that disincentive effects and increased wage pressures dominate those affecting search effectiveness through income support. Reducing benefit entitlements may therefore reduce unemployment via lower reservation wages and higher exits from the unemployment pool.

The estimated results give some support to the hypothesis that stringent **employment protection legislation** contributes to high unemployment and non-employment rates<sup>33</sup>. As such, they are consistent with Lazear (1990) who indicated a negative (albeit weak) association between the unemployment rate and EPL. These results conflict, however, with those of Bertola (1992) who was unable to find any relationship between unemployment levels and employment adjustment costs.

Tables 2 to 4 clearly indicate that employment protection rules have a more significant effect on the structure of employment and unemployment, putting upward pressure on youth and long-term Unemployment. The estimated effects of EPL on unemployment in both the youth unemployment and the LTU equations are larger and more significant than those observed in the total unemployment equations<sup>34</sup>. These results are consistent with an insider-outsider explanation of

LTU and youth unemployment. Higher firing costs may cause firms to change their hiring strategies towards increased “screening” of job applicants. This is likely to work to the detriment of inexperienced workers and the long-term unemployed whose long absence from work may have caused a deterioration of their skills or be interpreted by firms as indicating low expected productivity. However, turnover costs are only a necessary and not a sufficient condition allowing insiders to bid for higher wages at the expense of employment opportunities for outsiders. The way in which wages are bargained may also contribute. Indeed, the sensitivity analysis discussed in Annex C suggests that the explanatory power of the EPL index changes significantly if explicit account is taken of its likely interaction with the wage bargaining system, that is, with union density and the centralisation of co-ordination variables.

There is also evidence in Table 1 (equation 2) that **worker bargaining power** (proxied by union density) may lead to higher Unemployment, unless it is accompanied by a well co-ordinated bargaining process (COOR)<sup>35</sup>. In corporatist countries, **co-ordination among employers** (see equation 1 in Table 1) can significantly reduce structural unemployment insofar as such co-ordination provides a mechanism by which labour market pressures can be internalised into wage formation, increasing the sensitivity of wages to aggregate events. In the alternative specification, **the degree of centralisation/decentralisation of wage bargaining** is also important. The estimated coefficients of both CLWB and its square (equation 8 in Table 1) have the expected signs (although they are not always significantly different from zero). Albeit weak, these results confirm the hump-shaped hypothesis described above, whereby both highly centralised systems and fully decentralised systems help to restrain the wage claims of insiders and thereby contain unemployment.<sup>36</sup> The sensitivity analysis (Annex C) also reveals that there are close interactions between union density, co-ordination and centralisation. The analysis suggests that higher co-ordination seems to be always associated with lower equilibrium unemployment rates, regardless of the level of unionisation. The relative performance of centralised systems depends more importantly on the degree of unionisation. Highly centralised systems seem to be associated with lower unemployment outcomes as long as unionisation is not too high. Decentralised systems are also associated with lower unemployment, although the overall impact is of a smaller scale.

Institutional factors affecting the wage bargaining system are found to have an even stronger impact on youth unemployment, LTU and non-employment (Tables 2-4). In the case of youth unemployment, the results provide further support to the insider-outsider thesis, whereby young workers and new entrants into the labour market are particularly affected by the strong position of insiders (as proxied by UDENS) who may set wages above market-clearing levels. Similarly, high union

density, if accompanied by low co-ordination, may increase the average duration of unemployment (LTU)

It is also noticeable that the **two indices of foreign “competition”** (TRESTR and INTER) in Table 1 generally have a positive sign, as predicted, although the coefficients have large standard errors. Given the expected links between a lack of product market competition, rents, and rent-sharing behaviour, it is not surprising that the LTU and non-employment equations (Tables 3 and 4) suggest that the lack of foreign competition has a significant effect on the most vulnerable job seekers, if not on all the unemployed

Table 1 does not give support to any effect of the **tax wedge** on overall unemployment, in contrast to previous results (Pichelmann and Wagner, 1986; Layard and Nickell, 1986). The use of a marginal tax wedge instead of the average tax wedge does not alter this result noticeably. Despite the negligible effect on overall unemployment, Table 3 reveals that high non-wage labour costs may affect significantly long-term unemployment rates. Since the long-term unemployed are often low-paid workers, this result seems consistent with the idea a high tax wedge may affect their employment prospect, especially in those countries where binding wage floors prevent taxes to shift fully on wages. Further investigation is, however, needed in this area especially to assess the links between binding wage floors (such as minimum wages) and tax wedges.

Finally, there is no evidence in Table 1 that over the 1983-1993 period changes in the **terms of trade** (equation 4) or changes in the **long-term interest rates** (equation 5) have significantly affected labour market conditions

### The persistence of unemployment

Let us now turn to the persistence of unemployment and to its possible determinants. This requires, as stressed in the previous section, the extension of the period of analysis to the 1970s and early 1980s. The first two columns of Table 5 show the degree of persistence in unemployment for 17 OECD countries over the period 1970-1993 for which data are available. They report the probability of accepting the unit-root hypothesis, *i.e.* full hysteresis, against the alternative of a stationary process with a constant (column 1) and with a constant and a trend (column 2). The results point to highly persistent unemployment rates in many OECD countries, although in several cases it is difficult to discriminate between the notion of full hysteresis and that of slow adjustment, as also reported in Elmeskov and MacFarlan (1993)

Recalling equation [9] in the previous section, the actual unemployment rate can be expressed as the sum of the short-term equilibrium rate and a cyclical component. The short-term equilibrium rate is a function of lagged unemployment and those factors affecting the long-run equilibrium unemployment, namely the

policy and institutional factors – as well as the real interest rates and the terms of trade – considered in the previous section. Furthermore, the coefficient for lagged unemployment ( $h$ ) can be expressed as a function of labour market policy and institutional factors – namely the UB index, the EPL index and the wage-setting variables<sup>37</sup> As for the static specification, two alternative equations are considered, one where union density is complemented by the co-ordination index and another where union density is complemented by the index of centralisation of wage bargaining and its square Equation [9] can therefore be specified as follows

$$u_{it} = \mu_i + \left[ \begin{array}{l} \alpha_0 + \beta_1 UB_{it-1} + \beta_2 EPL_i + \beta_3 UDENS_{it-1} + \\ \beta_4 (COOR_i, \text{ or, } CLWB_i \text{ and } CLWB2_i) \end{array} \right] u_{it-1} + \beta_5 UB_{it} + \beta_6 UDENS_{it} + \beta_7 IRL_t + \beta_8 TERMS_{it} + \beta_9 GAP_{it} + v_{it} \quad [10]$$

where  $i$  indices countries and  $t$  the years,  $\mu_i$  is the country-specific constant and the other acronyms have the same meaning as above

Using non-linear Seemingly Unrelated Regression (SUR) estimators, equation [10] with the co-ordination index yields

$$u_{it} = \mu_i + \left[ \begin{array}{l} -0.69 \quad +0.002UB_{it-1} \quad +0.021EPL_i \quad +0.002UDENS_{it-1} \quad -0.045COOR_i \\ (1934) \quad (4.74) \quad (9.56) \quad (3.56) \quad (-8.66) \\ +0.01UB_{it} \quad +0.01UDENS_{it} \quad +0.07IRL_{it} \quad -0.27TERMS_{it} \quad -0.32GAP_{it} \\ (5.73) \quad (2.12) \quad (9.70) \quad (-15.43) \quad (-32.52) \end{array} \right] u_{it-1} + \quad [11]$$

$\mu_i$  = country dummy, No of observations = 391, t-statistics are in parentheses and are computed from heteroscedastic-consistent standard errors

Alternatively, using the indices of centralisation of wage bargaining

$$u_{it} = \mu_i + \left[ \begin{array}{l} -0.36 \quad +0.001UB_{it-1} \quad +0.0012EPL_i \quad +0.001UDENS_{it-1} \quad +0.061CLWB_i \quad -0.003CLWB2_i \\ (6.86) \quad (2.79) \quad (6.40) \quad (1.88) \quad (8.37) \quad (-7.31) \\ +0.02UB_{it} \quad +0.02UDENS_{it} \quad +0.81IRL_{it} \quad -0.24TERMS_{it} \quad -0.32GAP_{it} \\ (8.15) \quad (3.74) \quad (10.12) \quad (-13.33) \quad (-32.47) \end{array} \right] u_{it-1} + \quad [12]$$

$\mu_i$  = country dummy, No of observations = 391, t-statistics are in parentheses and are computed from heteroscedastic-consistent standard errors

Despite their simplicity, the two versions of equation [10] explain a significant fraction of the variation in unemployment rates over a 24-year period. All coefficients are correctly signed and generally significantly different from zero. To assess the quality of these estimates, the third and fourth columns of Table 5 compare the regression standard error for each country based on equations [11] and [12] with those from a simple autoregressive model with constant and drift estimated for each country in isolation. The two cross-country structural equations outperform the autoregressive model in 13 cases and only in two cases (Japan and Sweden) does the AR model clearly offer better results. The last three columns of Table 5 report the estimated degree of persistence which is particularly high in several European countries, e.g. Belgium, Italy, Portugal, Spain and Germany

These results complement those from the static analysis. In addition to affecting equilibrium unemployment, generous unemployment benefits reduce the adjustment speed, which is in line with the observed effect on the duration of unemployment spells, as shown in the LTU equations above. Consistent with the insider-outsider hypothesis, strict employment protection legislation as well as high unionisation seem to increase the persistence of unemployment, presumably by raising real wage rigidity. Moreover, the adjustment speed is increased by a higher degree of co-ordination/centralisation in the wage bargaining process. In addition, the parameters for the degree of centralisation of wage bargaining provide further support to the hump-shaped hypothesis. Both highly centralised or decentralised systems significantly increase the adjustment speed, suggestive of reduced real wage rigidity containing the build up of persistent unemployment. There is also some evidence that both the increase in real interest rates<sup>38</sup> during the 1980s and the deterioration of the terms of trade in the aftermath of the two oil shocks served to raise structural unemployment.

#### **Accounting for the differences in level and evolution of structural unemployment**

Table 6 summarises the results presented in the previous two subsections. Panel A breaks down the difference between each country's structural unemployment rate and the OECD average into its constituent parts, namely differences in ALMPU, unemployment benefits and institutional settings plus a residual which accounts for unobserved country-specific factors. The parameters referring to institutional factors include the joint impact of wage bargaining setting and employment protection regulations on unemployment without attempting a further breakdown given the close interactions among these factors. The results confirm that differences in the ALMPU stance explain only a small proportion of unemployment differentials, while a marked role is played by the different generosity of the unemployment benefits. In particular, in countries like Denmark, Belgium, the Netherlands and France, the UB system may explain as much as 3 to 5 percentage points of the unemployment rate differential. In some European countries, high unionisation combined with a lack of co-ordination in the wage bargaining process and stringent employment protection legislation contribute to explain their high unemployment rates. These latter results should, however, be evaluated carefully as these variables are defined on the basis of subjective evaluations and do not represent precise estimates of the magnitude of these effects.

The estimated country-specific effects – or unexplained residuals – are presented in the last column of Panel A.<sup>39</sup> A positive value means that the included explanatory variables would predict a lower-than-observed unemployment rate, and that other missing variables are needed to explain the remaining unemployment. Along the same lines, a negative estimated value implies that unobserved factors

contribute to lower the true unemployment rate. It should be stressed that, overall, only a small portion of the cross-country unemployment rate differentials is left unexplained, the major exceptions being Spain and Portugal where unobserved components account for 40-50 per cent of the total unemployment rates. Other European economies such as Belgium, France and Denmark also have relatively large unexplained residuals. In the first case, the model predicted unemployment rates higher than those observed, while in the case of France and Denmark the omitted factors seem to raise unemployment above the predictions of the model. The positive country-specific effects of Spain and France can partly be explained by the underestimation of the role of unions in wage bargaining. In both countries union density is very low, yet collective bargaining coverage rates are very high (70 to 90 per cent, respectively) and, in the case of France, they have been growing during the past two decades. Moreover, in these two countries, and particularly in France, the effects of binding minimum wage regulations – not considered in this paper – may also account for part of the unexplained residuals.

Panel B on the right-hand side of Table 6 gives a breakdown of the rise in structural unemployment from 1971 to 1993 into its constituent parts. For each country, the estimated parameters of equation [11] and the actual values of the exogenous variables were used to compute the changes in unemployment that we would expect from the changes in each of the explanatory variables.<sup>40</sup> Hence, Panel B presents Spain, Ireland and Denmark as the economies with the highest increases in structural unemployment, while only negligible increases occurred in Japan and the United States. The rise in UB generosity explains a great deal of the increases in structural unemployment, especially in Spain and Ireland. High UB replacement rates have a direct impact on unemployment, as shown in the static analysis, and also a severe impact on the speed of labour market adjustment. Falling unionisation rates in many countries lowered unemployment, but the overall effect has been generally limited. Higher real interest rates contributed between 1 and 3 percentage points to the increase in structural unemployment, with particularly severe effects in countries such as Portugal, Belgium, Italy and Spain with powerful persistence mechanisms. Moreover, the deterioration of the terms of trade affected unemployment only to a limited extent, the main exception being Australia where it accounted for 1.6 percentage point increase in unemployment. As before, country-specific effects are significant, particularly in some European economies where other omitted factors contributed to push up unemployment above the levels predicted by the model. For these latter countries further work is needed to explain the rise in structural unemployment over the past two decades.

## CONCLUDING REMARKS

This paper has offered a number of explanations for the differences in labour market performance across OECD countries over the past two decades. In particular,

it has estimated the relative importance of various labour market policy and institutional factors on both the level and dynamic behaviour of unemployment. It will always remain impossible to measure and model, in an entirely satisfactory manner, the wide variety of institutional, cultural and historical factors that influence labour market performances. In this paper, unexplained differences and country-specific measurement errors are identified through a country-specific error term, making the estimated impact of *observable* variables on unemployment more accurate and thus offering a better guidance for the assessment of policy reform.

The main conclusions of this paper can be summarised as follows:

- High levels of **unemployment benefit entitlements** are likely to lead to higher levels of unemployment and reduce the speed of labour market adjustment after an exogenous shock. The rise in the replacement rates over the past two decades in several OECD countries is estimated to have accounted on average for 1 to 3 percentage points increase in structural unemployment, although in some cases the effect has been greater.
- **Strict employment protection regulations** are likely to raise equilibrium unemployment rates significantly, they appear to have stronger positive effects on youth and long-term unemployment. Likewise, the dynamic analysis points to a significant positive impact of these regulations on the persistence of unemployment.
- The impact of different systems of wage determination on labour market performance is more difficult to assess, not least because of the complexity of the interactions among the different components of each system, and difficulties in measuring them precisely. As previous studies have shown, worker bargaining power – proxied by **union density** – seems to be associated with higher unemployment, although the relationship is often weak. Reinforcing the notion that youth unemployed are often “outsiders”, union density seems to have a particularly strong impact on youth unemployment.
- However, union density *per se* offers a very incomplete picture of the wage bargaining system. The **co-ordination** among the social partners at the different levels of the bargaining process as well as the level at which wages are negotiated (centralisation/decentralisation) should also be taken into account. In particular, co-ordination among employers seems to reduce unemployment levels and increase employment insofar as it offers a mechanism by which labour market pressures are internalised into wage formation, increasing the sensitivity of real wages to unemployment. The estimated effects of different degrees of **centralisation of wage bargaining** on unemployment are less clear-cut. Both highly centralised and decentralised bargaining systems appear to outperform intermediate, semi-centralised bargaining systems. These results confirm previous studies and support the idea

---

that the worst possible organisation of bargaining systems is the “*in-between*” solution of semi-sectoral or sectoral wage bargains where unions compete with each other without internalising the economy-wide costs of higher wages and higher unemployment

- **Active labour market programmes (ALMPs)** appear to have a negative impact on unemployment. However, the evidence suggests that increases in spending on ALMPs do not translate into equi-proportional falls in unemployment since the programmes give rise to large substitution and displacement effects on employment. The empirical findings also suggest a robust correlation between ALMPs and non-employment rates, confirming that these policies could have a positive effect of labour force participation, keeping otherwise discouraged workers in the labour force

## NOTES

1. Here and in the rest of this paper, we refer to EU-12 and data for Germany refer to Western-Germany.
2. The non-employment rate is the sum of unemployed workers and inactive divided by the total working age population.
3. For simplicity, the impact of unemployment on (log) wages is assumed to be linear in [2]. As often stressed, however, the relationship may be concave insofar as the downward pressure of unemployment on real wages may be decreasing at the margin as unemployment rises.
4. For simplicity, in this example we have assumed that the factors which shifted the **WS** and **LD** schedules did not influence either wage flexibility ( $\gamma_1$ ) or the elasticity of labour demand ( $a$ ). Relaxing these assumptions implies that changes in these factors will **not** only shift the **WS** and **LD** schedules but also affect their slopes. Moreover, if participation decisions are also affected, the full-employment schedule (**LS**) will also shift, thereby affecting the measured level of structural unemployment.
5. As stressed below, several variables proxying policy and institutional factors are not available on a time-series basis but only on a cross-sectional basis (see Annex A).
6. The direct extension of the static equation [8] to account for lagged unemployment effects is not suitable for empirical analysis. The use of OLS would yield biased results in the presence of country-specific effects  $\mu_i$  (Hsiao, 1986). The common methods of either using dummy variables (as pursued in this paper), or taking first-differences (Nickell, 1981; Anderson and Hsiao, 1981) make it impossible to include time-invariant variables ( $\mathbf{z}_i$ ) to account for cross-country differences in  $u_i^*$ .
7. The assumption of an identical parameter for the **GAP** variable across all cross-sectional units does not affect significantly the estimated coefficients for the other explanatory variables. An alternative equation with country-specific coefficients for the **GAP** variable produced similar results.
8. The use of a different measure of the **GAP** based on “potential” output (see Giorno et al., 1995) did not significantly affect the estimates of the coefficients of the other explanatory variables.
9. Calmfors and Lang (1995) offer an analytical framework for analysing the macroeconomic effects of active programmes.

10. Heylen (1993) found that increased expenditures for active labour market programmes per unemployed person (as well as a larger share of active spending in total spending) tended to increase the wage responsiveness to changes in open unemployment.
11. A similar approach was also used by Zetterberg (1993) who considered the share of active measures in total labour market expenditures; and by Heylen (1991) who used active expenditures (in purchasing power dollar values) per unemployed.
12. This would occur if active programmes are more effective when unemployment is higher than when it is low, because the risk of raising insiders' strength in wage bargaining is reduced and the possibility of improving the matching process is enhanced (Calmfors, 1994).
13. If active expenditures increase less than proportionally with unemployment, as often observed, the use of per-unemployed measures leads to simultaneity bias that tends to overestimate the impact of ALMP on unemployment. However, no alternative proxy of the active policy stance seems capable of dealing satisfactorily with this problem. For example, the use of a ratio of total spending on ALMP over the labour force (or the wage bill), as in OECD (1993), is likely to lead to simultaneity bias in the opposite direction, as total expenditures *do* increase – albeit less than proportionally – with unemployment. A different strategy would be to use instrumental variables (IV). However, it is generally difficult to find suitable instruments for ALMPU. An attempt was made using total government spending as the instrument for ALMPU, but the approach was not pursued because of the very limited power of the instrument in explaining variations in ALMPU. See also Jackman (1995) and Calmfors and Skedinger (1995).
14. Over the period from mid-1980s to 1993, the correlation between the rate of inflow into active programmes and the unemployment rate was positive in France (0.76), Canada (0.75), Australia (0.66), Denmark (0.93), Ireland (0.73) and Sweden (0.98) and negative only in Germany (–0.70) and the Netherlands (–0.18).
15. At the macro level, studies by Bean (1989), Layard *et al.* (1991) and Layard and Nickell (1992) found a positive association between unemployment and the UB replacement ratio (Bean) on the one hand, and the duration of benefits (Layard and Nickell; Layard *et al.*) on the other. At the micro level there is an extensive literature which mainly points to a significant effect of benefits on unemployment duration; some of the most recent references are reported in OECD (1994b, Chapter 8). Pedersen and Westergård-Nielsen (1993) also offer a comprehensive survey.
16. There are at least four key features of any given unemployment benefit system which may have effects on aggregate unemployment and its structural components: *i*) the replacement rates of both “insurance-based” benefits (if available) and social assistance benefits; *ii*) the maximum duration of both types of benefits; *iii*) the linkages between unemployment benefits and other income support schemes; and finally *iv*) the eligibility conditions and screening procedures for obtaining the benefits. For example, Layard *et al.* (1991) suggest that the fall in British unemployment after 1986 could be partially due to the stricter conditions introduced in the benefit scheme in that year (see Chapter I). By the same token, Abbring *et al.* (1995) found that in the Netherlands transition rates from unemployment to employment were significantly raised by the imposition of

sanctions eg. benefit reductions designed to make the recipient comply with certain rules on search behaviour.

17. The index takes into account three family situations – single worker, married worker with spouse at work and with spouse not at work. However, it does not consider the presence of children in the household nor does it consider housing benefits.
18. The rationale for using U63 in the youth equations is that the duration of unemployment insurance benefits is often related to the previous work experience and many young unemployed workers may not qualify for benefits over the maximum duration.
19. Employment protection regulations include rules governing unfair dismissals, lay-offs for economic reasons, severance payments, minimum notice periods and administrative authorisation for no-fault dismissals.
20. As stressed by Grubb and Wells (1993), all such surveys may offer results which are sensitive to details of wording and interview methods used. See Section IV in their study where several examples of changes in the perception of the strictness of EPL were found even in the context of unchanged regulations.
21. Among others, see Tyrvainen (1995) for empirical simulations of the effects of tax increases under alternative assumptions about the degree of competition in labour markets.
22. However, the hump-shaped hypothesis has also been criticised. In particular, Soskice (1990) claims that Japan and Switzerland were wrongly classified as decentralised by Calmfors and Driffill, ignoring the role of powerfully co-ordinated employer organisations and networks in these countries. If these two countries are re-classified as centralised, Soskice demonstrated – on the basis of only 11 countries – that unemployment will be a monotonic decreasing function of centralisation.
23. In a cross-country study, Rowthorn (1992) confirmed the hump-shaped association between centralisation and unemployment for the 1980s but not for the 1970s. See also Calmfors (1993) for an up-to-date survey of the studies in this field.
24. The collective bargaining coverage rate (the number of workers covered by the terms of collective agreements) is not included because of lack of data for the 1970s and also because of its high correlation with the centralisation index. Evidence suggests, in fact, that the coverage rate is often lower in countries characterised by single-employer bargaining compared with those where wage agreements are set at the sectoral or nation-wide level. See OECD (1994a), Chapter 5.
25. The choice of the world real interest rate instead of the domestic rates is also justified by the difficulty in interpreting the very low (or negative) domestic rates prevailing in the 1970s in some OECD countries without considering the concomitant distortions in their capital markets.
26. See for instance, Bruno and Sachs (1985); and Layard and Nickell (1986).
27. The full set of 17 countries includes: United States, Japan, Western Germany, France, Italy, United Kingdom, Canada, Australia, Belgium, Denmark, Finland, Ireland, Netherlands, Norway, Portugal, Spain, and Sweden. In the youth unemployment equations, the panel does not include Belgium and Denmark for which data are not available.

28. In the presence of country-specific effects, OLS estimates are biased and the direction of the bias cannot be identified *a priori*.
29. Error-component models assume that the effects of omitted variables reflect individual time-invariant differences. These effects are treated as random variables, in line with the assumption on other components of the random disturbance term ( $v_{it}$ ). In this context, the overall error term could be written as:

$$\varepsilon_{it} = \mu_i + v_{it}$$

The error-components model offers unbiased and efficient (with respect to fixed-effect) estimators under the assumption that the unobservable elements of the individual component  $\mu_i$  are not correlated with the observable regressors included in the model. The Hausman (1978) test has the null hypothesis that  $E(\mu_i | X_i, Z_i) = 0$  against  $E(\mu_i | X_i, Z_i) \neq 0$ . Under the null hypothesis, Hausman's test statistic is distributed asymptotically as a central chi-square with  $P$  degrees of freedom, where  $P$  is the number of time-varying regressors. Hausman notes that, under  $H_0$ , the GLS achieves the Cramer-Rao lower bounds, but under  $H_1$  the GLS estimators are inconsistent and the fixed-effects estimators should be used instead. See also Arellano (1993) for the treatment of correlation of unobservable individual effects with right-hand-side variables.

30. Details about the statistical information used and data sources are in Annex A.
31. Since the estimated statistics were not too far from the 1 per cent limit, the FGLS estimators were still used because the alternative of using country dummies or *within-group* estimators did not permit to estimate the coefficients of time-invariant explanatory variables. However, since there is a (weak) indication of a possible misspecification, these results should be evaluated with care.
32. Equation [2] in Table I yields  $u = -0.05 \text{ ALMPU} + \text{other explanatory variables}$  or, alternatively,  $u = -0.23 \text{ ALMPU} + \text{other explanatory variables}$ , if Sweden is excluded from the sample. The ALMPU variable can also be written as  $(E_p \cdot p) / (u \cdot y)$ , where  $E_p$  = expenditures per participant;  $p$  = programme participants relative to labour force (in per cent);  $u$  = unemployment rate (in per cent); and  $y$  = GDP per capita. if  $u = 8$ , ALMPU = 22 per cent (or 13 per cent without Sweden) and assuming that  $p = 3$ , expenditure per participant as a share of GDP per capita is  $E_p / y = 58$  per cent (or 34 per cent excluding Sweden). Under the additional assumption that all ALMP participants are in the labour force, the implicit differentiation would yield  $du/dp \cong -0.45$  (or  $\cong -1.48$  without Sweden). Assuming that the labour force is constant and defining  $n$  as the regular employment rate ( $n = 100 - u - p$ ), then  $dn/dp = d(100 - u - p)/dp \cong -0.55$  (or  $\cong 0.48$  without Sweden). See also Calmfors (1994) for similar calculations using the results of Layard. *et al.* (1991) and those of Zetterberg (1993).
33. A negative correlation between the employment/population ratio and indices of the "strictness" of EPL is also confirmed in Chapter 6 of the *Jobs Study* (Table 6.9) and, on a more qualitative basis, in a survey by the EC Commission. This latter survey reports that in countries which have relatively strict employment protection (e.g. Italy and Spain), more than half of the firms surveyed reported hiring and firing costs as one of the reasons for not hiring more workers. See EC *Ad Hoc* Survey: Commission of the European Communities, European Economy, No. 47, March 1991.

34. The results for LTU confirm previous findings by Heylen (1991) and **OECD** (1993, Chapter 3).
35. Similar results were obtained by Layard and Nickell (1992) and Layard *et al.* (1991).
36. The estimated coefficients suggest a peak at a CLWB value of 12, which corresponds to the United Kingdom. For Italy, Japan, the United States and Canada, increased decentralisation would lower unemployment, whilst for the other countries increased centralisation would reduce unemployment.
37. ALMPU has not been included because of lack of data for the 1970s and early 1980s.
38. It should be stressed, however, that the real interest rate variable is likely to play the role of a shift variable in equations [11] and [12], as it was very low in the 1970s and significantly higher in the 1980s, when structural unemployment was also higher. Therefore, the estimated positive impact of interest rates on unemployment may be partially spurious as it may simply reflect a change in regime which depends upon other omitted factors such as e.g. productivity growth.
39. The country-specific effects ( $\mu_i$ ) can be derived as follows:

$$\hat{\mu}_i = \left( \frac{\sigma_{\mu}^2}{\sigma_{\varepsilon}^2} \right) j'_{\tau} (y_i - X'_i \hat{\beta} - Z'_i \hat{\gamma})$$

where  $j'_{\tau} = (1, 1, \dots, 1)$ ;  $\sigma_{\mu}^2$  is the variance of  $\mu$ , and  $\sigma_{\varepsilon}^2 = T\sigma_{\mu}^2 + \sigma_v^2$ ;  $\mu$  is the random country-specific effect and  $v$  is the usual error term.

40. Equation [11] was simulated dynamically over the entire period, with each exogenous variable in turns taking its actual value while the others were kept constant. The 1970 initial condition for each country's unemployment rate was set equal to the long-run steady state equilibrium rates, as derived from the parameters of equation 11 and the observed values of the exogenous variables in 1970.

## Annex A

**DESCRIPTION OF THE VARIABLES**

Descriptive statistics of the variables used in this paper are included in Table A.1. The text below presents the methods used to derive the variables and information on the data sources.

Table A 1 **Characteristics of the annual data of the OECD countries**

Variables	(average values for the 1983-1993 period)				(average values for the 1970-1993 period)			
	Mean	Standard deviation	Minimum	Maximum	Mean	Standard deviation	Minimum	Maximum
UNST	8.41	4.81	1.46	22.40	6.01	4.07	0.03	22.39
NER	35.60	9.92	18.25	56.51				
YUR	16.55	10.43	3.20	43.80

**UNST** = For all but Denmark, standardised unemployment rates are from Labour Force Surveys (LFS). Since LFS data were not available for the 1970s, the unemployment rates for Denmark refer to registered unemployed and are from the OECD Economic Outlook (various issues). The unemployment rates have been adjusted in order to reduce the number of breaks in the series for the different countries.

*Source:* OECD, Directorate for Education, Employment, Labour and Social Affairs (DEELSA).

**YUR** = Youth unemployment rate; individuals from 15/16 to 24 years of age. Data are from Labour Force Surveys.

*Source:* OECD-DEELSA

**LTU** = Long-term unemployment rate; individuals with unemployment spell longer than 12 months to the labour force. Data are from Labour Force Surveys.

*Source:* OECD-DEELSA.

**NER** = Non-employment rates. The share of the working-age population which is either unemployed or inactive.

*Source:* OECD-DEELSA

**GAP** = output gap;

$$\text{GAP} = \left( \frac{A_o}{T_o} - 1 \right) * 100$$

where:

A<sub>o</sub> = actual output; see OECD ADB database

T<sub>o</sub> = trend output. It is based on a GDP smoothing approach using an Hodrick-Prescott Filter. A value of  $\lambda = 25$  was used for most of the countries. See Giorno *et al.* (1995) for more details

*Source:* OECD Analytical Database (ADB).

**ALMPU** = expenditures for active labour market programmes per unemployed person relative to GDP per capita (in per cent);

$$\text{ALMPU} = \frac{\frac{\text{ALMPex}}{U}}{\frac{\text{GDP}}{\text{Pop}}}$$

ALMPex = expenditures on active labour market programmes (see *OECD Employment Outlook - 1993*, Annex 2.B, for details).

Pop = working age population

U = total registered unemployed

*Source*; OECD, *Employment Outlook*, various issues and OECD ADB.

**UB** = the average of the unemployment benefit replacement rates for two earnings levels, three family situations and three duration categories of unemployment. Information on replacement rates in the OECD database is only available for odd-numbered years. Even-numbered years were calculated using linear interpolation. After-tax replacement rates were obtained from the OECD *lobs Study* (Annex 8.B) interpolating the ratios (net/gross rates) for 1971, 1981, 1991. After-tax replacement rates for 1992 and 1993 were calculated using the 1991 ratios (net/gross rates)

*Source*: OECD *Database on Unemployment Benefit Entitlements and Replacement Rates*; and OECD *lobs Study*, Annex 8.B.

**UB2** = as UB but including only replacement rates for spells longer than one year.

**UB3** = as UB but including only replacement rates for the first year of unemployment.

**EPL** = index of the "strictness" of employment protection legislation. The index is the average of two rankings for regular and fixed-term contract workers, respectively. The index refers to 1989.

*Source*: OECD (1994), *The OECD lobs Study*, Table 4.7, second column.

**ECOOR** = extent of inter-firm co-ordination in the process of wage bargaining. The index varies from 1 to 3, with 3 referring to maximum co-ordination, both here and in UCOOR.

*Source*: Layard *et al.* (1991), Chapter 1

**UCOOR** = extent of inter-union co-ordination in the process of wage bargaining. It is also graded from 1 to 3.

*Source*: see ECOOR.

**COOR** = ECOOR + UCOOR

**CLWB** = ranking of the degree of centralisation of wage bargains. The lower the position in the ranking, the higher is the degree of centralisation.

*Source:* Calmfors and Driffill (1988), Table 11.

**UDENS** = the proportion of workers who are members of trade unions. Available observations refer to 1970, 1980 and 1990 (see footnote to Table 5.7 of the OECD *Employment Outlook – 1994* for country details). Missing observations were calculated by a linear interpolation.

*Source:* OECD *Employment Outlook – 1994*, Chapter 5, Paris.

**TWEDGE** = the ratio between the total value of employers' social security contributions, employees' social security contributions and personal income tax plus the amount of consumption tax typically paid if all post-tax income is consumed and gross earnings plus employers' social security contributions

*Source:* OECD (1995), *The Tax/Benefit Position of Production Workers*, Paris; Tyrvaïnen (1996).

**COMP** = index of exposure to foreign competition:

$$\text{COMP} = X_i + (1 - X_i) \text{MP}$$

where:

$X_i$  = index of export intensity (ratio of exports to GDP);

MP = index of import penetration (ratio of imports to apparent consumption, that is, domestic production minus exports plus imports).

*Source:* OECD (1995a), The OECD ADB.

**TRESTR** = the index of pervasiveness of trade restrictions reported in Table B.1 in Annex B.

**INTER** =  $(\text{COMP} * \text{TRESTR})/100$

**IRL** = GDP-weighted average of real long-term interest rates. The latter were estimated as the difference between nominal long-term interest rates and expected inflation. Nominal long-term interest rates are yields on benchmark public sector bonds of around 10 years maturity. Expected inflation are generated using the low-frequency component of the annual percentage change in the GDP deflator using a Hodrick-Prescott filter. In the filtering process, a lambda value of 1600 was used

*Source:* OECD ADB.

**TERMS** = weighted terms of trade. The terms of trade are calculated as the ratio of export unit value and import unit value; data are multiplied by the average (1970-1993) value of COMP.

*Source:* OECD ADB.

*Annex B*

## INDICATORS OF THE PERVASIVENESS OF TRADE RESTRICTIONS

A number of summary indicators reflecting the level, pattern and pervasiveness of tariffs and non-tariff barriers (NTBs) have recently been computed by the OECD. Three indicators have been used in this paper to define our measure of the pervasiveness of trade restriction (TRESTR).

To capture the main features of each country's tariff structure, we used:

- The overall simple average *ad valorem* Most Favoured Nation (MFN) tariff rate.
- The overall standard deviation (SD) for all tariff lines

To capture the pervasiveness of NTBs we used

- The overall frequency ratio of “core” NTBs.

The simple MFN tariff rate captures the average *level* of protection afforded to specific groups of domestic products and thus sheds some light on the potentially distorting effects on domestic resource allocation, particularly between tradeable and non-tradeable sectors. The *dispersion* of tariff rates across all products and within specific groups of products sheds some further light on the potential distortions in economic efficiency.<sup>1</sup> For any given level of average tariff, the greater the overall and particularly the within groups (of similar, and consequently substitutable products) variability, the greater the likelihood that resources are mis-allocated due to distorted consumers' and producers' decisions.

The frequently ratio for “core” NTBs indicates the proportion of national tariff lines that are affected by this particular group of NTBs.<sup>2</sup> Thus, it indicates the *existence* of NTB measures, without providing any indication of their actual restrictiveness or impact on prices and economic efficiency. Nevertheless, the NTBs indicator can be used to shed some light on the patterns of NTBs within OECD countries and to highlight the sectors in which they are concentrated

## THE SUMMARY INDEX

Columns 1 to 3 in Table B.1 report the 1988 country averages of tariff rates, the variability of tariffs and NTBs, respectively. These averages have been calculated from sectoral data involving a breakdown of the manufacturing sectors in 36 (ISIC) branches plus agriculture.<sup>3</sup>

The simple country-averages of tariffs and NTBs may not be an accurate indicator insofar as the relative importance of the different sectors affected by tariffs and NTBs vary greatly across OECD countries. To assess the overall protection afforded by both tariffs and NTBs, columns 4 to 6 in Table B.1 report weighted tariff averages and NTB coverage ratios based on each sector's share in value-added.<sup>4</sup> EU countries

Table B.1. **Summary indicators of the pervasiveness of tariff and non-tariff trade barriers in a selected group of OECD countries**

	1		2		3		4		5		6		7

Australia	11.0	10.1	15.9	2.1	0.6	9.5	83.5							

1 industry average tariffs and NTBs weighted by each sectors share of total value added

2 The weighted average of the normalised values of columns 4-6 where the weights for the MFN tariff and SD were 0.5 and the weight for NTBs was 1. Data were normalised by setting the cross-country average equal to 100

Source: See text in Annex B

differ in the weighted averages, despite the common EU trade policy, because of the different sectoral composition of their economy.

The final step of our exercise was to extract from the weighted averages of tariffs and NTBs a summary index which could account for the overall potentially distorting effects of trade policy. This summary index is presented in column 7 of Table B.1: it is a weighted average of the normalised values of columns 4 to 6. It is obviously difficult to assess on a *priori* grounds the relative importance to tariffs and NTBs on prices and economic efficiency. Our choice of the weights assigns equal importance to tariffs and NTBs (e.g. weight = 1 in both cases). For tariffs, however, both the level and variability are considered (e.g. each of the two measures receive a weight of 0.5).

## NOTES

1. It should be stressed that a uniform nominal tariff (or uniformly restrictive **NTB**) minimises the net welfare cost of such protection only if import demand elasticities are uniform across commodities, there are not intermediate inputs and cross-price effects are negligible.
2. See OECD (1996) for more details on the definitions of “core” **NTBs**.
3. The estimation of value-added-weighted tariffs and **NTBs** required: *i*) the establishment of concordances between the commodity-based Harmonised System (**HS**) in which data were originally available and the production-based **ISIC** code; *ii*) the aggregation of the resulting data at the level of the **36** manufacturing branches for which detailed information is available in the **OECD-STAN** database plus agriculture; and, *iii*) the computation of value-added weights for the **36 + I** sectors.
4. Value-added weights avoid the downward bias inherent in import-weighted indicators, although they may imply that highly-protected sectors are over represented. See **OECD** (1996).

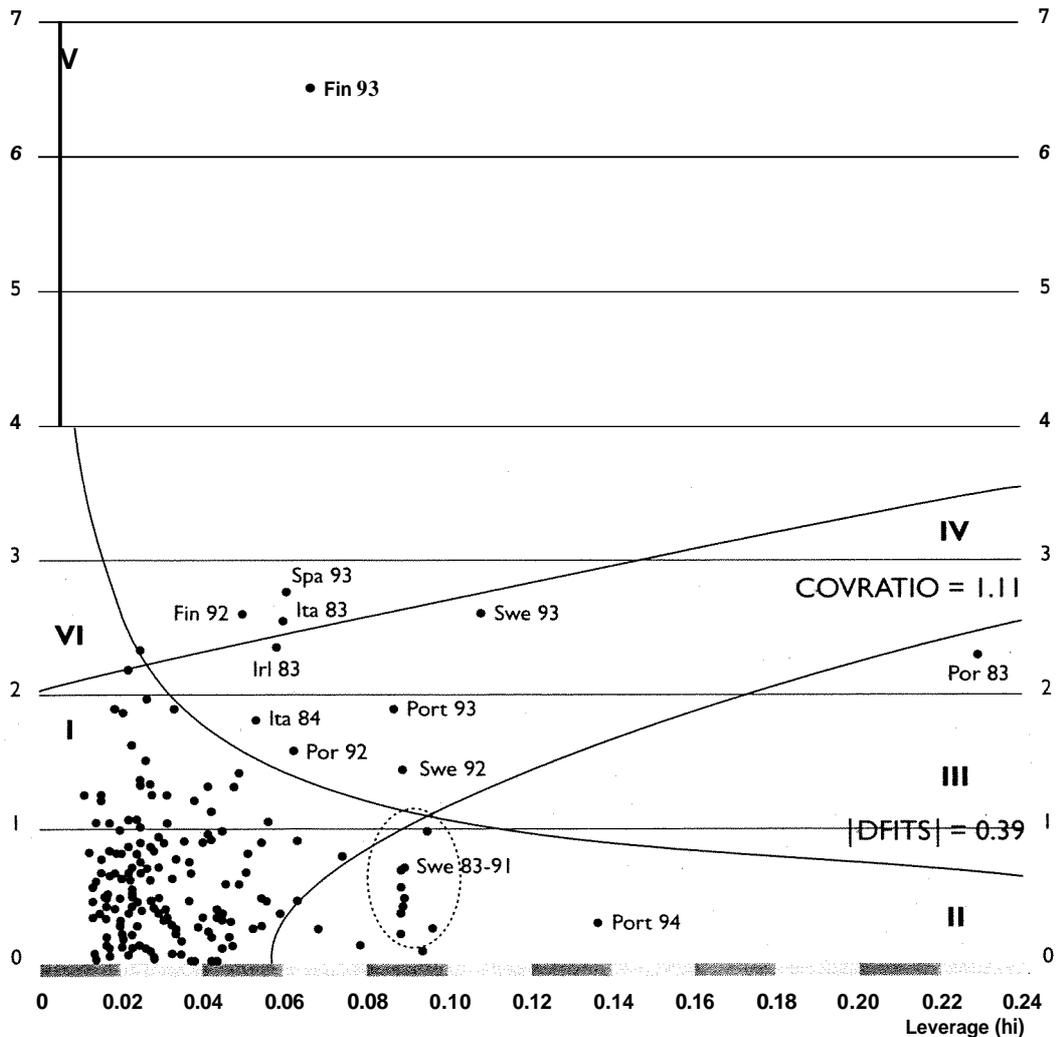

## Annex C

**SENSITIVITY ANALYSIS****OUTLIERS AND INFLUENTIAL DATA**

In any empirical investigation – and particularly those based on a small panel of cross-section time-series data – it is important to identify subsets of the data that appear to have a disproportionate influence on the estimated equation. The objective of this section of the annex is to identify these data points and assess their impact on the estimated parameters. As suggested by Fiebig (1987), a distinction should be made between outliers and influential data. The first group includes those observations which appear to be inconsistent with the remainder of the data set and are generally identified by large standardised residuals. Influential points are those that affect significantly the inference drawn from a data set.<sup>1</sup> Two indicators are used to identify outliers and influential observations (see Belsley *et al*, 1980; Fiebig 1987):

- To identify outliers we used the *studentised residuals* ( $r_i$ ). This is obtained by considering a mean-shift outlier model in which the basic equation is augmented by a dummy variable  $d$ , that has the  $i$ th element equal to one and all other elements zero. The studentised residual  $r_i$  is the  $t$ -statistics of the dummy variable and values above 2 indicate possible outliers.
- To identify influential observations we used the *leverage points* ( $h_i$ ) identified by the diagonal elements of the least-squared projection matrix, also called the hat matrix. The leverage points  $h_i$  proxies the distance between the  $i$ th observation and the centre of the data. Belsley *et al* (1980) suggest a size-adjusted cut-off value at  $2p/nobs$ , where  $p$  is the number of explanatory variables and  $nobs$  is the total number of observations.

Using the results of equation 2 in Table 1 as a benchmark, Figure C 1 plots the magnitude of  $r_i$  against  $h_i$ , the so called leverage-residual plot, (Fiebig, 1987). Points which are not outliers nor influential are clustered around the origin of the axes while disparate observations are characterised by large residuals or large leverage or a combination of both factors. In order to isolate better these observations two regression diagnostics are also superimposed on the LR plot, namely the DFITS (in absolute values) and the COVRATIO which can both be expressed as a function of  $r_i$ ,

Source: OECD

and  $h_i$ . DFITS measures the influence of an individual observation on the predicted dependent variable or fitted values. When the deletion of a single observation causes a significant change (see below) in the predicted value, it deserves further attention. COVRATIO is the ratio of the covariance matrix of the estimated coefficients obtained when the  $i$ th row has been deleted and the covariance matrix obtained with all the data. Therefore, COVRATIO measures the effect of an individual observation on the efficiency of the coefficient estimation. A COVRATIO value

lower than unity indicates a reduction in the efficiency, while a value greater than unity indicates increased efficiency.

The size-adjusted cut-off value for  $|DFITS|$  is  $2\sqrt{p/nobs}$  (equal to 0.39 in our case), while the size-adjusted cut-off values for COVRATIO are  $1 \pm 3p/nobs$  (equal to 0.89 and 1.11 in our case), see Belsley *et al* (1980). The iso-influence contours for DFITS and COVRATIO in Figure C.1 identify six regions. Region I contains points which are neither influential for DFITS nor for COVRATIO. This is the region where most of the observations are concentrated. Region II comprises points which have high leverage but small residuals. These points improve the efficiency even if they may affect significantly the estimates of specific parameters (see below). Region III includes points with high leverage but not too large residuals. For points in Region IV, residual and leverage are both relatively large but in terms of COVRATIO the two effects tend to offset each other. They are worth further examination, even if they are not likely to affect significantly the estimated parameters. Region V comprises points with a high residual, while Region VI identifies points which are characterised by a high residual but low leverage. Points in this region are important for COVRATIO but not for DFITS.

Within this framework, Figure C.1 indicates 6 data points as particularly influential: Port83, Port84, Fin92, Fin93, Ita83 and Spa93. In particular, the Portuguese data for 1983 seem to be disparate because of both large residuals and leverage; the Portuguese data for 1984, on the contrary, have small residuals but significant leverage; the Finnish data for 1993 have very large residuals but low leverage; and, finally, the data for Finland 1992, Spain 1993 and Italy 1983 have all significant residuals but are not particularly influential for the efficiency of the coefficient estimates. Furthermore, data for Sweden for the 1983-1991 period have all COVRATIO exceeding the cut-off. The latter, however, have low residuals and thus do not affect the overall results of the regression significantly.

Since our interest is mainly on the influence of each of these data points on the estimated individual coefficients, Table C.1 reports several diagnostics, including the DFBETAS which measure the change in each individual coefficient resulting from the deletion of each of these data points.

Data for Finland for the 1992-1993 period have a significant impact on most of the coefficients. This is due to the very sharp increase in unemployment rates during these two years when unemployment rose by 10 percentage points to 17.7 per cent. The Portuguese data also affect some of the estimated coefficients, albeit for the opposite reason to that of Finland. In Portugal, the unemployment rate declined during the 1980s to 5-6 per cent, despite the relatively stable labour market and institutional setting there and the growing unemployment rates in the most of the other European economies. It is also noticeable that the Swedish data, albeit not effecting the overall fit, do affect the estimated coefficient for ALMPU,

The estimates are based on equation 2 in Table 1. See the text for details on the calculation of the different indices

\* Exceeds cutoff values:  $|r_i| > 2.0$ ,  $hi > 0.0749 (2p/nobs)$ ;  $|DFBETAS| > 0.146 (2/\sqrt{(nobs)})$ . *Nobs* = number of observations. *p* = number of explanatory variables

Source: See text in Annex C

which is no surprise since this country spent almost four times as much on active programmes as the OECD average.

## INTERACTIONS BETWEEN EXPLANATORY VARIABLES

Table C 2 reports the changes in the estimated coefficients obtained by deleting one explanatory variable in turn. This exercise is useful to see whether the effect of each variable on unemployment is enhanced (reduced) by the omission of other regressors. In broad terms, the table suggests that the omission of one aspect of the bargaining process reduces the significance of the others. Moreover, the estimated effect of EPL on unemployment is strongly affected by the inclusion/exclusion of the unemployment benefit variable and the wage bargaining variables.

Table C.3 sheds some further light on the interactions between the different factors characterising the wage bargaining process. Two equations are used, one considering the co-ordination index and three indexes accounting for the interactions between union density and the different levels of co-ordination, alternatively, the index of centralisation is used together with three indexes accounting for the

interaction with the union density. In this second case, the original CLWB ranking of countries is replaced by a simpler index which identifies low, medium and high centralisation (CORP1, CORP2 and CORP3, respectively)<sup>2</sup>. The co-ordination variables seem to have a strong role to play in the bargaining process, regardless of the level of union density. The interaction between union density and the degree of

Source see Annex A

centralisation of the bargaining process is more complex, as also suggested by the hump-shaped hypothesis discussed in the main text. Intermediate levels of bargaining, (*i.e.* at the level of industry) seem to be always associated with higher unemployment. High centralisation seems to contribute to contain unemployment pressure: taking into account the estimated coefficient for CORP3 and the interaction

factors (INTER1 to INTER3), the impact of greater centralisation is negative, that is, it will reduce unemployment until unionisation is below 60 per cent. After this limit is passed (only Denmark, Finland and Sweden have more than 60 per cent of the work force unionised), worker bargaining power tends to offset the benefits accruing from centralisation. Decentralised systems too, are associated with lower unemployment.

## NOTES

1. It should be stressed that the concepts of outliers and influential data do not overlap: an observation may be an outlier but not overly influential or may be influential even if associated with a small standardised residual.
2. Following Calmfors and Driffil (1988) and the OECD *Employment Outlook - 1994* (Table 5. 1), the 17 countries of the panel have been classified as follows: low centralisation (CORP1) United States, Japan, Italy, United Kingdom, Canada; medium centralisation (CORP2) Germany, France, Belgium, Ireland, Netherlands, Portugal, Spain and Australia; high centralisation (CORP3) Denmark, Finland, Norway and Sweden.

## RESUMEN EJECUTIVO

Las transferencias monetarias y los programas de ayuda del gobierno proveen un apoyo importante a los grupos en desventaja económica en la Isla, pero también han creado un desbalance en los incentivos que tienen las personas para participar del mercado de trabajo. Este no es el único factor, pero sí uno de los factores responsables por el poco dinamismo del mercado laboral puertorriqueño.

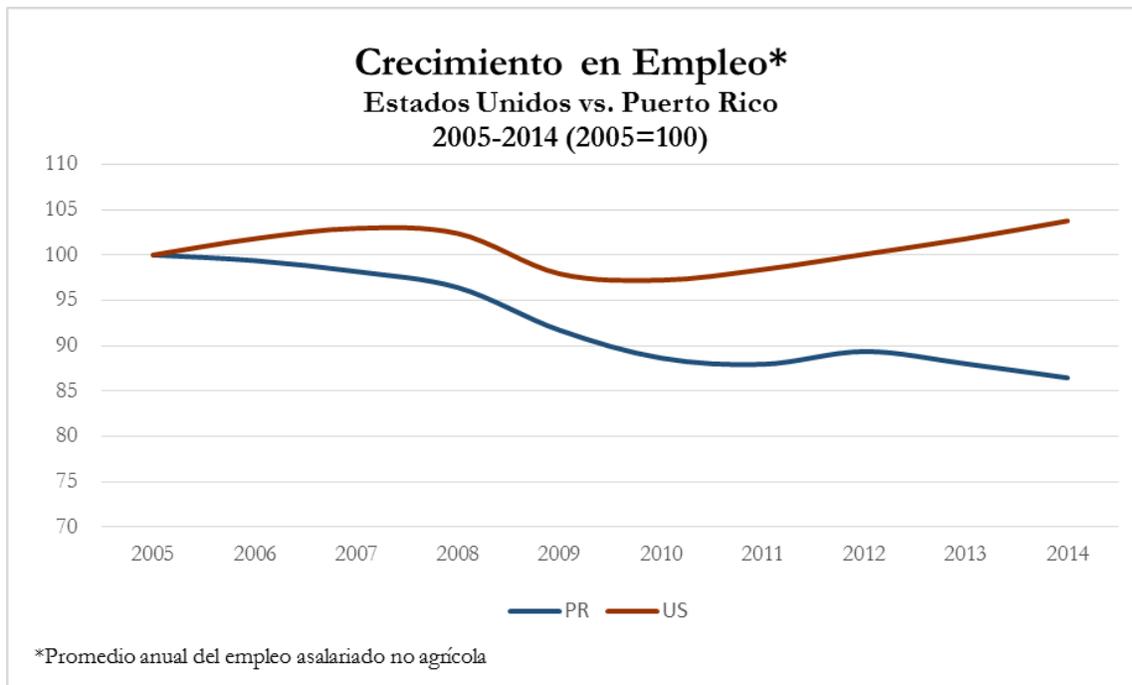

Uno de los hallazgos importantes de este estudio es que el valor total de los beneficios derivados de estas ayudas es cercano, y en algunos casos, sobrepasa los ingresos por concepto de salario si se trabajara a salario mínimo. Si el salario disponible en el mercado es igual o menor que los beneficios que la persona podría recibir estando laboralmente inactiva, sería irracional —en el sentido económico— conseguir y mantener un empleo. De hecho, toda vez que el disfrute del ocio tiene un valor económico para las personas, la decisión de estar activo en el mercado de trabajo requiere que el salario disponible sea superior por un margen razonable al conjunto de pagos de transferencia que se pueden recibir sin trabajar.

Otra consecuencia importante de toda esta situación es el número indeterminado de familias que están recurriendo a trabajos en la economía informal para no perder los beneficios de las ayudas del gobierno. Esto es una situación preocupante que tiene repercusiones en la asignación de los recursos y que puede dejar desprovistas a familias con necesidades más apremiantes.

Programas como los servicios de *Head Start* y *Early Head Start* ayudan a que una madre pueda trabajar a tiempo completo, particularmente si se combinan con otros programas (*Child Care, Pre-Kinder*) para que el infante esté atendido todo el día.

En el año 2006, se creó una política pública de dar un crédito por trabajo para aquellas personas que devengaban ingresos de hasta \$10 mil anuales. Este crédito se eliminó en el 2014 como parte de la reestructuración fiscal del Gobierno de Puerto Rico. Además, la difícil situación económica que atraviesa Puerto Rico presenta un panorama de búsqueda de empleo no muy alentador.

Al observar el crecimiento en empleo en los últimos años en Estados Unidos se observa un crecimiento moderado con muestras de recuperación. Sin embargo, el panorama de empleo en Puerto Rico luce preocupante.

## I. INTRODUCCIÓN

La Universidad Interamericana de Puerto Rico Recinto Metropolitano junto a *Human Services Research Partnership Puerto Rico* (HSRPPR) ha desarrollado una iniciativa en la que, en unión a otros sectores privados y públicos de Puerto Rico, promocionan la necesidad de evaluación de los acercamientos, servicios y prácticas relacionadas a las familias pobres y niños en Puerto Rico.

Uno de los programas que se está evaluando por el comité de investigadores es el Programa de Ayuda Temporal para Familias Necesitadas (TANF). El TANF ofrece a sus participantes una ayuda económica temporera que les permite entrenarse y crear las condiciones para alcanzar la autosuficiencia económica mediante la obtención de un empleo. A diferencia de otros programas de asistencia social, el propósito de este programa es lograr que miembros de las familias participantes se incorporen a la fuerza laboral y puedan eventualmente sustentarse por sí mismos.

En los análisis y observaciones preliminares se ha notado que algunas mujeres cualificadas para el beneficio de TANF optan por no trabajar en la economía formal en función de un salario mínimo y continuar con las ayudas económicas gubernamentales.

A través del documento se discutirá si existe un beneficio o una desventaja monetaria de trabajar bajo el salario mínimo o decidir no trabajar para poder recibir todos los beneficios que pueden obtener.

## II. ANÁLISIS DE LA ESTRUCTURA FAMILIAR

Para realizar el siguiente análisis se tomó en consideración el umbral de pobreza federal para el 2015. Véase tabla a continuación.

Umbral de Pobreza Federal 2015							
Total de Miembros en el Hogar	<u>100%</u>	<u>133%</u>	<u>150%</u>	<u>200%</u>	<u>250%</u>	<u>300%</u>	<u>400%</u>

Fuente: Federal Register, Volume 80 Issue 14

Los perfiles que se presentan a continuación fueron producidos por la base de datos *Integrated Public Use Microdata Series (IPUMS)*. Una de las más grandes bases de datos que se nutre del *American Community Survey* del 2000-2013 y del Puerto Rico *Community Survey* desde el 2005-2013. Las variables utilizadas para llegar a nuestros estimados fueron las siguientes: *total family income, number of own family members in household, marital status, any health insurance coverage y number of own children in the household*.

Al analizar los perfiles de Puerto Rico se puede observar los cambios demográficos que ha tenido la población para el periodo 2010-2013. Los cohortes de edad que más se han afectado por el cambio demográfico son los grupos jóvenes donde se observa una reducción considerable. Estos grupos son precisamente los que tienen el mayor porcentaje de personas sin seguro médico. Al desagregar por cohorte de edad, la población de menos de diecinueve (19) años es la que más se ha reducido, contrario a la población de más de sesenta y cinco (65) años que viene en aumento.

### Cambio Demográfico de la Población Total de Puerto Rico

Al analizar la población de Puerto Rico que no cuenta con un seguro médico, ésta totalizó poco más de 239 mil para el 2013, siendo la tasa de población sin seguro médico de 6.62%. El tamaño del hogar más común entre la población no asegurada es de tres (3) miembros. De este grupo (tres miembros en el hogar) un poco más de 9 mil personas tienen ingresos de menos de \$10 mil anuales. Dentro de los no asegurados, hay un grupo significativo en el que solo hay una persona viviendo en el hogar.

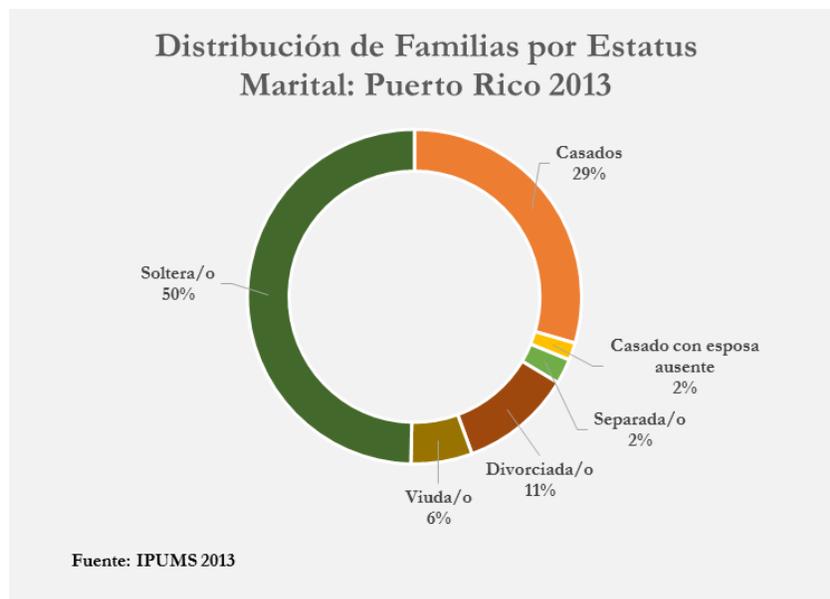

En la población sin seguro médico hay 58 mil personas que deberían cualificar para el programa de Mi Salud, ya que los ingresos son menos de \$10 mil anuales.

### III. CRITERIOS DE ELEGIBILIDAD Y BENEFICIOS DE LOS PROGRAMAS DE ASISTENCIA SOCIAL Y ECONÓMICA

#### Programa de Asistencia Nutricional (PAN)

El Programa de Asistencia Nutricional conocido como PAN ofrece ayuda económica a familias de escasos recursos para que puedan cubrir sus necesidades alimentarias. Las personas que son elegibles al beneficio de mi PAN tienen que utilizar el 75% de los beneficios en compras de alimentos y el 25% restante puede ser obtenido en dinero en efectivo a través de un cajero automático.

Los requisitos del programa son los siguientes: tener residencia en Puerto Rico y tener capital (cuenta de ahorros, cuenta corriente, etc.) de hasta \$2,000. Los hogares con una persona de sesenta (60) años o más pueden tener un capital de hasta \$3,000. Los hogares en Puerto Rico tienen que cumplir con un límite de ingreso neto que varía según el número de personas en el hogar. El ingreso neto se calcula tomando el monto total de ingresos del hogar y restando las deducciones por tipo de ingreso, número de miembros en el hogar, y ciertos gastos permitidos. Los criterios de elegibilidad por miembros del hogar se presentan a continuación.

**Tabla de Beneficio e Ingreso Neto Máximo: PAN**

### Sección 8

El programa Sección 8 se crea bajo la Ley de Vivienda y Desarrollo Urbano (HUD en adelante) en el 1974. El beneficio del programa es el ofrecimiento de un subsidio para rentar una residencia a familias de bajos ingresos. Los requisitos básicos del programa son ser categorizada como una familia, cumplir con los límites de ingresos establecidos por HUD, ser ciudadano americano y ser mayor de edad. En Puerto Rico existen varias agencias tanto municipales como estatales que ofrecen los servicios de Sección 8. Cabe resaltar que el programa les provee a las familias unos vales para que puedan buscar un apartamento o residencia apropiado. La cantidad de vales están limitados y siempre hay listas de espera.

HUD establece los límites de ingreso según el ingreso mediano de la familia tanto por área metropolitana y municipal. Además para establecer estos límites se toma en consideración la composición de la familia. En la tabla a continuación se presentan los límites de ingreso de Puerto Rico para el año fiscal 2015.

Límites de Ingreso Puerto Rico: Programa Sección 8 - 2015								
Ingreso Mediano de la Familia	<u>1</u> Persona	<u>2</u> Personas	<u>3</u> Personas	<u>4</u> Personas	<u>5</u> Personas	<u>6</u> Personas	<u>7</u> Personas	<u>8</u> Personas
<b>\$19,700</b>

Programa WIC

El programa WIC le provee ayuda nutricional a toda mujer que cumpla con los requisitos que establece el programa. Estos son: mujer embarazada, mujer postparto hasta seis (6) meses después del parto, mujer lactante hasta un (1) año después del parto, infante hasta su primer año y niño hasta su quinto año de edad. La solicitante debe de vivir o trabajar cerca de la zona que cubre la Clínica WIC. Para participar en el programa debe de cumplir con las guías de ingresos del gobierno federal. Las personas que participan en dicho programa automáticamente pueden solicitar los programas del PAN, Mi Salud, TANF y los programas de *Early Head Start* y *Head Start*. A continuación se presenta la tabla de elegibilidad.

Guía de Elegibilidad por Ingreso para el Programa WIC					
Tamaño del Hogar	Anual	Mensual	Quincenal	Bi-mensual	Bi-semanal
1	\$21,590	\$1,800	\$900	\$831	\$416
2	29,101	2,426	1,213	1,120	560

<b>Miembro Adicional</b>	<b>7,511</b>	<b>626</b>	<b>313</b>	<b>289</b>	<b>145</b>

Nota: Efectivo desde 1 de julio de 2014 hasta el 30 de junio de 2015.

**Programa de Ayuda Temporal para Familias Necesitadas (TANF)**

El propósito del programa TANF es ofrecer a sus participantes (familias de bajos recursos con hijos) un ayuda económica temporera que les permita entrenarse y crear las condiciones para alcanzar la autosuficiencia económica mediante la obtención de un empleo. El programa tiene como propósito reducir los niveles de pobreza de las familias mediante servicios de colocación laboral y recursos comunitarios y profesionales que están a disposición de los participantes y los empleadores. El TANF ofrece un subsidio de 100% del salario por doce (12) meses a los negocios o entidades que empleen a los participantes del programa, además de proveer una red de recursos comunitarios y profesionales al servicio de estas entidades. El TANF es una ayuda temporera que se les otorga a las familias que cualifiquen para incorporar o re-incorporar a uno de sus miembros a la fuerza laboral y que puedan eventualmente sustentarse por sí mismos.

A continuación se presenta la tabla de necesidades básicas ajustadas de alimentos, ropa, efectos personales, luz, agua y combustible. Esta cifra que se le paga mensual a la persona o familia y no incluye el albergue.

**Programa Mi Salud**

Mi Salud es el seguro de salud del Gobierno de Puerto Rico el cual asegura a toda la población médico-indigente del país. Este es administrado por la Administración de Seguros de Salud (ASES). Mi Salud es uno de los seguros de salud más completos en términos de cubierta cuando se compara con otros seguros comerciales disponibles en el mercado. El umbral de pobreza para cualificar para este programa es de hasta un 200%, es decir, el máximo de ingreso para una persona cualificar es de \$800 mensuales. Los beneficiarios del componente federal de Mi Salud (100-110 -nivel indigencia de 0-1), es la población que reporta tener de \$0-\$400 dólares de ingresos mensuales. El otro grupo son los “state”, los cuales son categorizados en los grupos de 320-330 (nivel indigencia de 2-3). Véase la tabla a continuación.

**Criterios de Elegibilidad Mi Salud**

### *Subsidio para Servicio Telefónico a través del Fondo de Servicio Universal*

Este programa le ofrece subsidios para los servicios de telecomunicaciones a toda persona de escasos recursos económicos que cualifiquen. Estos aplican al pago de la renta mensual al teléfono residencial o celular. El subsidio es aplicable a cualquier plan de servicio que incluya servicios de voz, incluyendo planes combinados de servicios de voz y data; planes que incluyan funciones opcionales tales como, pero no limitados a: identificación de llamadas, llamada en espera, correo de voz y llamadas en conferencia, y a planes de familia compartidos, por unidad económica familiar o por persona.

En Puerto Rico, el subsidio aplica al programa *Lifeline* y es por \$12.75. Este proviene de dos fondos: \$9.25 del Fondo del Servicio Universal Federal y \$3.50 del gobierno estatal. Para ser beneficiario la persona debe participar en algunos de los programas de ayudas del Gobierno.

### *Subsidio de Agua y Luz*

El subsidio de la Autoridad de Acueductos y Alcantarillados (AAA) representa alrededor del 30% de la factura. Para solicitar dicho subsidio los solicitantes deben de participar en el programa del PAN, TANF y/o tener sesenta y cinco (65) años o más. En el caso de la Autoridad de Energía Eléctrica (AEE), el subsidio aplica a los primeros 425 kW de consumo en el mes. Este subsidio varía dependiendo del ajuste de combustible y generalmente oscila entre \$7-\$9 al mes. Para este subsidio cualifican automáticamente estudiantes, personas de sesenta y cinco (65) años o más y personas participantes del programa PAN.

#### IV. ANÁLISIS DE INGRESOS A TIEMPO PARCIAL Y A TIEMPO COMPLETO

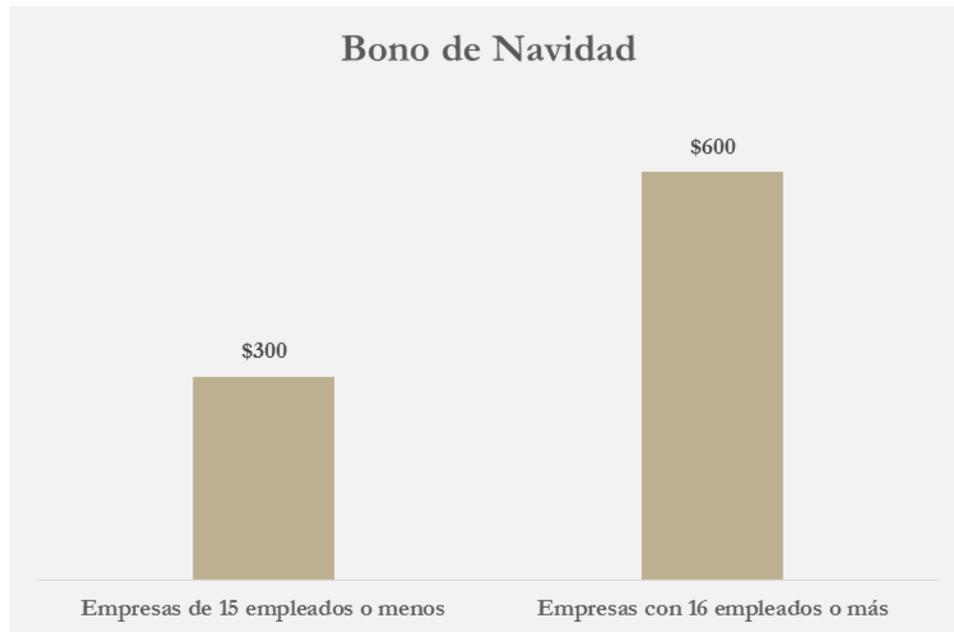

El Congreso de los Estados Unidos es la entidad gubernamental que determina el salario mínimo. En Puerto Rico, la Ley 80 del 27 julio 1998 conocida como la Ley de Salario Mínimo, Vacaciones y Licencia por Enfermedad de Puerto Rico, establece que la Ley de Normas Razonables del Trabajo aprobada por el Congreso de los Estados Unidos en el 1985 y sus enmiendas aplican automáticamente a Puerto Rico. Además, establece que aquellas empresas no cubiertas por la Ley Federal deberán pagar un salario mínimo equivalente al 70% del salario mínimo prevaleciente.

En los últimos años los aumentos en salario mínimo han ocurrido en una forma escalonada, por lo general, implantando el aumento en tres (3) o cuatro (4) años. El último aumento ocurrió en el año 2009 y es el salario mínimo por hora prevaleciente en la actualidad (\$7.25 por hora).

Una persona que tiene un trabajo de veinte (20) horas a la semana a un salario de \$7.25 por hora estaría generando un ingreso bruto anual de \$7,540. Sin embargo, se le aplican las deducciones que corresponden por Ley del Seguro Social 6.2%, Medicare 1.45% e incapacidad .30%. Para esta persona queda un ingreso neto anual de \$6,942 o \$579 mensual. Las mismas deducciones aplican a personas que trabajas cuarenta (40) horas a la semana, resultando en un ingreso neto anual de \$13,905 o \$1,158 mensual.

<b>Análisis de Salario Mínimo a Tiempo Parcial y a Tiempo Completo</b>			
	<b><u>Deducción %</u></b>	<b><u>Trabajador a Tiempo Parcial</u></b>	<b><u>Trabajador a Tiempo completo</u></b>
Horas Trabajadas		1,040	2,080
Pago por Hora		\$7.25	\$7.25
<b>Salario Bruto</b>		<b>\$7,540</b>	<b>\$15,080</b>
<b>Deducciones</b>			
Seguro Social	6.20%	\$467.48	\$934.96
Medicare	1.45%	\$109.33	\$218.66
Incapacidad	0.30%	\$21.00	\$21.00
<b>Total Deducciones</b>		<b>\$597.81</b>	<b>\$1,174.62</b>
<b>Salario Neto Anual</b>		<b>\$6,942</b>	<b>\$13,905</b>

Cabe resaltar que el beneficio del Bono de Navidad aplicaría para ambos empleados tanto a tiempo parcial como a tiempo completo, siempre y cuando el empleado a tiempo parcial cumpla con más de setecientas (700) horas de trabajo en un año. El bono mínimo por ley va a variar de acuerdo al número de empleados de la empresa. Véase la gráfica a continuación.

## V. ANÁLISIS CUANTITATIVO DE LOS BENEFICIOS

### *Beneficios Adicionales al TANF*

Al hablar de transferencias, es importante distinguir entre dos tipos de transferencias: las devengadas y las otorgadas. Las primeras son aquellas a las cuales las personas tienen un derecho adquirido (*entitlement*) por virtud de aportaciones pasadas, como en el caso del seguro social, desempleo y las pensiones de jubilación. Las segundas son las que reciben las personas sin haber hecho aportación alguna, por virtud de algún programa gubernamental que combate de la pobreza. En esta segunda categoría se destacan las transferencias del Programa de Asistencia Nutricional (PAN), las del sistema *Medicaid* y la beca para estudiantes universitarios *Pell Grant*.

En el caso de las transferencias que provienen del Gobierno de Puerto Rico (un poco menos de una cuarta parte del total), la mayoría son devengadas, ya que consisten principalmente de pagos de pensiones a empleados públicos retirados. La porción de las transferencias estatales que son otorgadas no se conoce con exactitud, pero es menor y consiste de pagos a la Reforma de Salud ahora conocida como Mi Salud y las aportaciones locales a los programas de beneficencia pública federal (por ejemplo, en la vivienda subsidiada de los residenciales públicos).

Las personas que cualifican para el TANF generalmente también cualifican para varias ayudas gubernamentales que provienen de fondos Estatales y Federales. Algunos de los programas son: Programa de Asistencia Nutricional (PAN), el Programa de Asistencia Médica (*Medicaid*), los Programas Early Head Start y Head Start y el WIC. Además, cualifican para los subsidios de agua, luz, teléfono y celular.

El subsidio de la Autoridad de Acueductos y Alcantarillados (AAA) representa alrededor del 30% de la factura. Para solicitar dicho subsidio los solicitantes deben de participar en el programa del PAN, TANF y/o tener sesenta y cinco (65) años o más. En el caso de la Autoridad de Energía Eléctrica (AEE), el subsidio aplica a los primeros 425 kW de consumo en el mes. Este subsidio varía dependiendo del ajuste de combustible y generalmente oscila entre \$7-\$9 al mes. Para este subsidio cualifican automáticamente estudiantes, personas de sesenta y cinco (65) años o más y personas participantes del programa PAN.

En cuanto a los beneficios de asistencia médica a personas médico indigentes, la cubierta del seguro médico que provee el Gobierno de Puerto Rico es una de las cubiertas más completas cuando se compara con las cubiertas de seguros médicos privados disponibles en el mercado. En estos momentos, el costo de un seguro médico individual con los beneficios de Mi Salud es de aproximadamente \$200 mensuales. Esta cantidad se estimó obteniendo una cotización con un seguro médico privado para una cubierta similar a la de Mi Salud. En este caso los seguros médicos comerciales que comparan con los beneficios de Mi Salud son los que se categorizan bajo planes de cubierta platino. Se utilizó el estimado de cotización para individuo, pareja y familiar.

En el caso del Programa de Sección 8, la mayoría de las familias o individuos que cualifican para el PAN, cualifican para este programa. A diferencia de otros programas, el disfrute de este beneficio está sujeto a la disponibilidad de vales. Para poder asignarle un valor al beneficio de Sección 8, se evaluó el alquiler equitativo del mercado (FMR, por sus siglas en inglés) que es la guía utilizada por HUD para el funcionamiento del programa y se ajustó por el número de miembros en el hogar. Este valor se estimó para poder ser incluido en la cuantificación del paquete total de beneficios. Aunque se reconoce que los beneficios de Sección 8 no son disfrutados por toda la población que cualifica, existen otros programas similares para la población de bajos ingresos como el de vivienda en residenciales públicos que cumplen con el mismo de objetivo.

Las personas que cualifican para los programas anteriormente mencionados, podrían beneficiarse también de los programas WIC y *Head Start* de tener bebés o niñas y niños menores de 5 años. La valoración de estos beneficios es difícil de realizar, ya que depende de variables que no se pueden estimar al momento porque varían dependiendo del tipo de familia.

La siguiente tabla muestra estima el valor total de las ayudas adicionales que podría recibir una persona que también cualifica para el programa TANF. Un hogar que se compone de dos personas el total de beneficios se estimó en casi \$965 mensuales. Como se indicó anteriormente, el paquete de beneficios puede resultar en una cantidad mayor debido a que los programas del WIC y *Head Start* no están incluidos en este análisis. El incluir al programa de Sección 8 en el estimado del paquete de beneficios hace que este paquete resulte más atractivo. Es decir, dicho programa podría resultar clave al momento de una persona o familia tomar la decisión de incorporarse o no a la fuerza laboral.

Estimado de Beneficios por Miembros del Hogar							
Beneficio Mensual							
Miembros en el Hogar	Departament o de la Familia	Departament o de la Vivienda	Departament o de Salud	Junta Reglamentadora de Telecomunicaciones de Puerto Rico	Subsidio de:		Total Beneficios

7	\$679	\$780	\$487	\$12.75	\$8	\$7.11	\$1,973
8	\$776	\$780	\$487	\$12.75	\$8	\$7.11	\$2,070

### *Beneficios Incluyendo al TANF*

TANF es un programa que ofrece a sus participantes una ayuda económica temporera que les permita entrenarse y crear las condiciones para alcanzar la autosuficiencia económica mediante la obtención de un empleo. A diferencia de otros programas de asistencia social, el propósito de este programa es lograr que miembros de las familias participantes se incorporen a la fuerza laboral y puedan eventualmente sustentarse por sí mismos.

La tabla a continuación presenta el paquete de beneficios incluyendo los beneficios del TANF. El programa TANF clasifica las necesidades básicas de las familias en tres categorías 50%, 100% y 185%. Estas necesidades básicas están ajustadas en lo siguiente: alimentos, ropa, efectos personales, luz, agua y combustible. Este ajuste no incluye el albergue.

## Estimado de Beneficios Ajustado por la Cantidad Mensual de Beneficio del TANF según el Número de Miembros en el Hogar

	Miembros en el Hogar	PAN	TANF	Subsidio Celular	Subsidio de Agua	Subsidio de AEE	Mi Salud	Sub-total	Sección 8	Total
	Necesidades Básicas TANF 50%	1	\$112	\$83	\$12.75	\$7.11	\$8	\$156	\$379	\$409

## VI. ANÁLISIS CUANTITATIVO DE LOS BENEFICIOS DE LAS AYUDAS Y TRANSFERENCIAS DEL GOBIERNO, SALARIO MÍNIMO Y SUS REPERCUSIONES EN EL MERCADO DE TRABAJO.

Esta sección compara el valor estimado para el paquete de beneficios de ayudas económicas gubernamentales disponibles en Puerto Rico con los ingresos que un individuo generaría de trabajar al salario mínimo (\$7.25 por hora) tanto a tiempo parcial como a tiempo completo. Como se ha dicho anteriormente el estimado de paquete de beneficios, con o sin TANF y Sección 8, son algo conservadores, ya que no contienen el 100% de las ayudas que las familias podrían recibir. Las siguientes tablas muestran los resultados

### *Paquete de Beneficios versus Trabajo a Tiempo Parcial*

En la tabla 1 se presenta el paquete de beneficios sin incluir TANF ni Sección 8. Sin estos dos programas un hogar de una persona genera \$283 dólares más al mes de trabajar a tiempo parcial versus no trabajar. Sin embargo, mientras más miembros hay en el hogar, la brecha entre el salario y el valor de los beneficios gubernamentales se reduce si se mantuviera una sola persona trabajando a tiempo parcial, hasta llegar inclusive a sobrepasar los ingresos por concepto de salarios. Por ejemplo, el paquete de beneficios de ayudas para una familia de tres (3) miembros es \$251 más que el salario generado por un miembro de la familia trabajando a tiempo parcial.

**Tabla 1:**

<b>Estimado de Beneficios sin TANF ni Sección 8 comparado con los Ingresos del Salario Mínimo a Tiempo Parcial</b>			
<u>Miembros en el hogar</u>	<u>Estimado de Ayudas Económicas</u>	<u>Estimado de Salario Mínimo a Tiempo Parcial</u>	<u>Diferencia</u>
1	\$296	\$579	<b>\$283</b>
2	\$556	\$579	<b>\$23</b>
3	\$829	\$579	\$251
4	\$924	\$579	\$346
5	\$1,013	\$579	\$435
6	\$1,113	\$579	\$535
7	\$1,193	\$579	\$615
8	\$1,290	\$579	\$712

En la tabla 2 se muestra el paquete de beneficios incluyendo los programas de TANF y Sección 8. El análisis se realizó utilizando las necesidades básicas del TANF del 100%. En este caso los beneficios generados por las ayudas sobrepasan los ingresos generados por concepto de salario a tiempo parcial en todos los tamaños de familia.

**Tabla 2:**

<b>Estimado de Beneficios con TANF y Sección 8 comparado con los Ingresos del Salario Mínimo a Tiempo Parcial</b>						
<u>Miembros en el hogar</u>	<u>Estimado de Ayudas Económicas</u>				<u>Estimado de Salario Mínimo a Tiempo Parcial</u>	<u>Diferencia</u>
	<u>Ayudas Económicas</u>	<u>TANF</u>	<u>Sección 8</u>	<u>Total Ayudas Económicas</u>		
1	\$296	\$166	\$409	\$871	\$579	\$292
2	\$556	\$290	\$409	\$1,255	\$579	\$676
3	\$829	\$414	\$500	\$1,743	\$579	\$1,165
4	\$924	\$538	\$500	\$1,962	\$579	\$1,384
5	\$1,013	\$662	\$679	\$2,354	\$579	\$1,776
6	\$1,113	\$786	\$679	\$2,578	\$579	\$2,000
7	\$1,193	\$910	\$780	\$2,883	\$579	\$2,305
8	\$1,290	\$1,034	\$780	\$3,104	\$579	\$2,526

### *Paquete de Beneficios versus Trabajo a Tiempo Completo*

En el caso de tener un trabajo a tiempo completo el escenario cambia. Resulta atractivo incorporarse a la fuerza laboral, ya que el ingreso generado de un salario a tiempo completo supera el valor del paquete de beneficios, principalmente para familias pequeñas. En la tabla 1 se puede ver claramente que sin recibir las ayudas del TANF y Sección 8 un salario a tiempo completo resulta atractivo.

Tabla 1:

<b>Estimado de Beneficios sin TANF ni Sección 8 comparado con los Ingresos del Salario Mínimo a Tiempo Completo</b>			
<u>Miembros en el hogar</u>	<u>Estimado de Ayudas Económicas</u>	<u>Estimado de Salario Mínimo a Tiempo Completo</u>	<u>Diferencia</u>
1	\$296	\$1,159	\$863
2	\$556	\$1,159	\$603
3	\$829	\$1,159	\$329
4	\$924	\$1,159	\$234
5	\$1,013	\$1,159	\$145
6	\$1,113	\$1,159	\$45
7	\$1,193	\$1,159	\$35
8	\$1,290	\$1,159	\$132

Sin embargo, cuando se incorpora al análisis los beneficios del TANF y Sección 8 la situación cambia (Tabla 2). El análisis se realizó utilizando las necesidades básicas del TANF del 100%. En este caso los beneficios generados por las ayudas sobrepasan los ingresos generados por concepto de salario a tiempo completo cuando la familia alcanza los dos (2) miembros.

Tabla 2:

<b>Estimado de Beneficios con TANF y Sección 8 comparado con los Ingresos del Salario Mínimo a Tiempo Completo</b>						
<u>Miembros en el hogar</u>	<u>Estimado de Ayudas Económicas</u>			<u>Total Ayudas Económicas</u>	<u>Estimado de Salario Mínimo a Tiempo Completo</u>	
	<u>Económicas</u>	<u>TANF</u>	<u>Sección 8</u>			<u>Diferencia</u>
1	\$296	\$166	\$409	\$871	\$1,159	\$288
2	\$556	\$290	\$409	\$1,255	\$1,159	\$96
3	\$829	\$414	\$500	\$1,743	\$1,159	\$585
4	\$924	\$538	\$500	\$1,962	\$1,159	\$804
5	\$1,013	\$662	\$679	\$2,354	\$1,159	\$1,196
6	\$1,113	\$786	\$679	\$2,578	\$1,159	\$1,420
7	\$1,193	\$910	\$780	\$2,883	\$1,159	\$1,725
8	\$1,290	\$1,034	\$780	\$3,104	\$1,159	\$1,946

Los programas de ayudas económicas proveen un apoyo importante a los grupos en desventaja económica en la Isla. Las transferencias a las personas, especialmente las que provienen del Gobierno Federal, constituyen un ingreso importante para los habitantes de Puerto Rico. A pesar de que Puerto Rico no cualifica para muchos programas federales en las mismas condiciones que los cincuenta (50) estados, la alta incidencia de la pobreza en la Isla conduce a que la importancia relativa de las transferencias a las personas sea mayor en Puerto Rico que en los estados. Esto tiene una serie de implicaciones para la economía puertorriqueña.

Los programas de ayudas económicas cumplen con un propósito social y de redistribución de ingresos pero tienen repercusiones en el mercado de trabajo, ya que no incentivan a las personas a participar del mismo; al menos si su potencial de ingresos es cercano al salario mínimo. Este es uno de los factores responsables del poco dinamismo del mercado laboral puertorriqueño. La decisión de las personas de no incorporarse al mercado de trabajo en un empleo a salario mínimo o cercano al salario mínimo está muy influenciada por el alto valor relativo de los programas de asistencia pública disponibles en la Isla.

Un trabajador-consumidor racional no va a querer dedicarle tiempo al trabajo si el costo de oportunidad de trabajar es mayor o igual que el ingreso que se devengaría por las horas trabajadas. En otras palabras, si el salario disponible en el mercado es igual o menor que los beneficios que la persona podría recibir estando laboralmente inactiva, sería irracional—en el sentido económico—el conseguir y mantener un empleo.

De hecho, toda vez que el disfrute del ocio tiene un valor económico para las personas, la decisión de estar activo en el mercado de trabajo requiere que el salario disponible sea superior por un margen razonable al conjunto de pagos de transferencia que se pueden recibir sin trabajar. El problema que esto presenta en el caso de Puerto Rico es que para la mayor parte de los trabajadores potenciales el salario disponible en el mercado es el salario mínimo, y éste no está muy lejos del valor total del “paquete” de beneficios que muchas personas pueden obtener manteniéndose laboralmente inactivos.

Un análisis de este problema lo realizó en el año 2006 el Centro para la Nueva Economía (CNE) y el Brookings Institution.<sup>1</sup> Utilizando el salario mínimo y los programas de beneficencia pública

<sup>1</sup> Gary Burtless y Orlando Sotomayor, “Labor Supply and Public Transfers,” capítulo 3 de *The Economy of Puerto Rico: Restoring Growth*, Brookings Institution y Centro para la Nueva Economía, Washington, D.C., 2006.

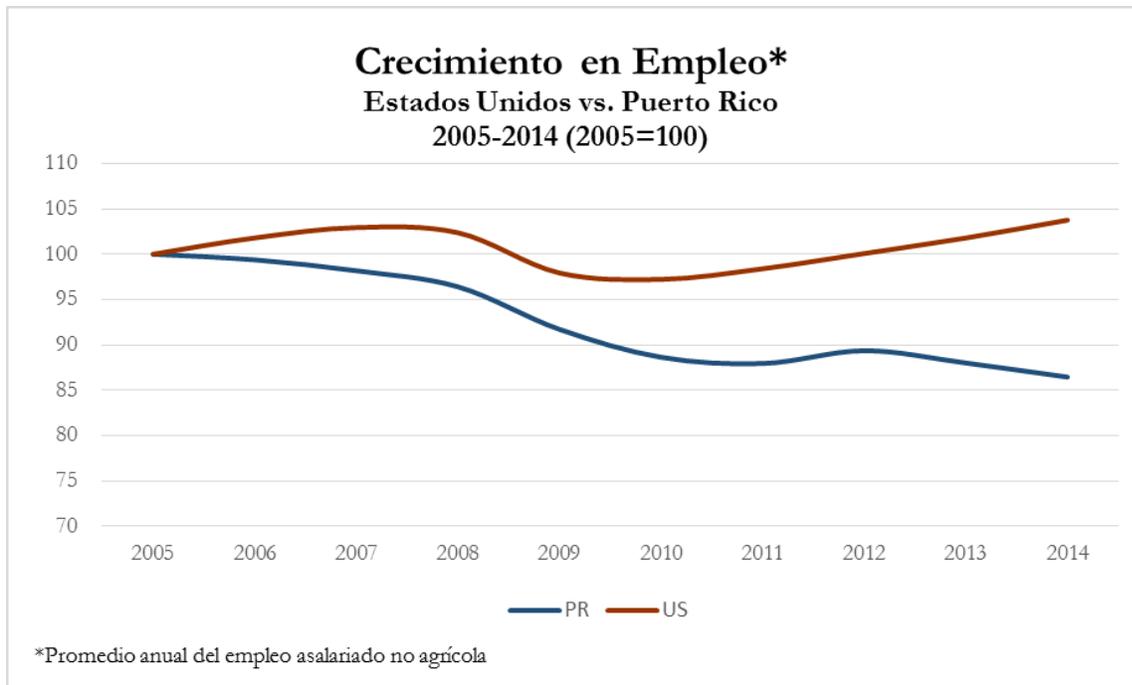

disponibles en el año 2003, los autores calcularon el beneficio neto mensual para diferentes tipos de consumidores-trabajadores de trabajar versus no trabajar y recibir beneficios.

La posibilidad de trabajar a salario mínimo, incluso tratándose de dos salarios mínimos en la familia, no es atractiva, ya que el beneficio mensual neto de trabajar es muy pequeño suponiendo, como es el caso, que al trabajar a tiempo completo (40 horas a la semana) se pierde la totalidad o casi la totalidad de los beneficios disponibles de los programas de transferencias. Esto debido a que los criterios de elegibilidad de cada programa estatal y federal están sujetos a criterios de ingresos. Además existen costos o gastos relacionados al trabajo tales como ropa de trabajo, almuerzos y transportación que no se están tomando en consideración en el análisis.

Es indiscutible que el valor de los beneficios que reciben las personas y familias en programas de ayudas es cercano y, como se pudo apreciar, en algunos casos sobrepasa lo que éstos podrían generar trabajando a salario mínimo. Esta situación hace que muchas familias decidan no trabajar. Además, la difícil situación económica que atraviesa Puerto Rico presenta un panorama de búsqueda de empleo no muy alentador.

Otra consecuencia importante de toda esta situación es el número indeterminado de familias que están recurriendo a trabajos en la economía informal para no perder los beneficios de las ayudas del gobierno. Esto es una situación preocupante que tiene repercusiones en la asignación de los recursos y que puede dejar desprovistas a familias con necesidades más apremiantes.

Al observar el crecimiento en empleo en los últimos años en Estados Unidos se observa un crecimiento moderado con muestras de recuperación. Sin embargo, el panorama de empleo en Puerto Rico luce preocupante.

## VII. CONCLUSIONES Y RECOMENDACIONES DE POLÍTICA PÚBLICA QUE AYUDEN A SUBSANAR LAS DEFICIENCIAS O LAS BRECHAS

Una de las conclusiones más importantes de este informe es que el valor total de los beneficios que reciben las familias bajo programas de ayuda y transferencias del gobierno no incentiva el que estas personas se inserten en la fuerza laboral. Como se expuso, el valor de estos beneficios es cercano, y en algunos casos, sobrepasa los ingresos por concepto de salario si se trabajara a salario mínimo. En el caso de madres o padres solteros la decisión de ingresar a la fuerza laboral se hace más difícil, ya que éstos tendrían que pagar por el cuidado de sus hijos.

La situación antes expuesta no sólo tiene repercusiones en la economía puertorriqueña y en el mercado de trabajo, sino que también incide de manera negativa en los objetivos del Programa TANF. Como se había planteado, el propósito principal del programa es precisamente el que las personas participantes se incorporen a la fuerza laboral y puedan eventualmente sustentarse por sí mismas.

El gobierno de Puerto Rico debe de idear una política pública que incentive el trabajo y que cree las condiciones para fortalecer y diversificar la oferta de trabajo a tiempo completo. En el año 2006, se creó una política pública de dar un crédito por trabajo para aquellas personas que devengaban ingresos de hasta \$10 mil anuales. Este crédito se eliminó como parte de la reestructuración fiscal del Gobierno de Puerto Rico en el 2014.

Ha estado bajo discusión la creación de un nuevo crédito por trabajo para familias con hijos que devengan un ingreso entre \$7,500 a \$25,000. En este caso estas familias cumplen con sus responsabilidades contributivas pero no pueden beneficiarse de ningún programa de beneficencia ya que sus ingresos son muy altos para cualificar para ciertos programas. Este tipo de ajuste es una forma de incentivar el trabajo formal.

Otros programas como los servicios de Head Start (HS) y Early Head Start (EHS) ayudan a que una madre pueda trabajar a tiempo completo. Como parte de este esfuerzo se propone alterar los mecanismos de ofrecer el servicio para ampliar la cobertura con el mismo presupuesto. Según establece el “Head Start Program Performance Standards” (45 CFR 1301-1311), las clases en estos centros deben llevarse a cabo con un máximo de seis (6) horas diarias pero establece como cuatro (4) horas el tiempo óptimo de aprovechamiento de las mismas.

De acuerdo a los hallazgos y conclusiones de este estudio, *Advantage* presenta las siguientes recomendaciones de política pública:

- Re-evaluar y re-diseñar el programa TANF
- Reincorporar el crédito por trabajo
- Evaluar la opción de que más centros HS operen en dos turnos de cuatro (4) horas en lugar de seis (6) en turnos de mañana y de tarde. (Actualmente hay más de cuarenta (40) centros trabajando en este tipo de arreglo).
- El servicio de día completo debe dar prioridad a familias que tengan necesidades de empleo y/o trabajo, además de dar prioridad para selección de turno (mañana/tarde) a dichas familias.
- Evaluar la posibilidad de que las familias paguen por horas de cuidado adicionales a las horas de HS para completar el tiempo de un día completo de servicio.
- Evaluar la posibilidad de proveer servicios complementarios a través de “vouchers” del programa “Child Care” en la medida en que hayan los recursos en este otro programa.
- Coordinación entre Administración para el Cuidado y Desarrollo Integral de la Niñez (ACUDEN) y el Departamento de Educación para compartir facilidades y servicios entre el programa HS y Pre-K. Entre HS y Pre-K se puede cubrir el día entero.

**Comments on ABC Consulting study for HSRPPR.  
“Beneficios de las Personas Elegibles al Tanf Vs. Escenario de Salario Mínimo Federal”**

**Prepared by Hector Cordero-Guzman, Ph.D.  
Co-Principal Investigator  
Building Human Services Research Partnerships in Puerto Rico (BHSRP)  
Inter-American University**

This document includes some comments and reactions to **ABC Consulting Study for HSRPPR:  
“Beneficios de las Personas Elegibles al Tanf Vs. Escenario de Salario Mínimo Federal.”**

This study is divided into seven sections that cover three main topics: the first is a demographic analysis of the low-income population using IPUMS data from the Puerto Rico Community Survey (PRCS) for 2013. More details need to be presented as to exactly what file was used (1yr, 3yr or 5ys) and the actual years covered. The report mentions that the variables analyzed include: *total family income, number of own family members in the household, marital status, any health insurance coverage, and number of own children in the household.*

The demographic section starts by showing population change for the major age groups and then proceeds to prepare a table of family income by number of household members. While this is interesting information, it is hard for the reader to get a clear sense of the proportion of the population below poverty by family size and that critical information can be presented in a separate table or highlighted in the present table. There are too many numbers and the table is hard to follow.

At the top of page 7 of the report the authors highlight that there are over 58,000 persons that qualify for health subsidy but do not appear to be receiving the health plan (Mi Salud) because they did not have health insurance. This is an important point to consider later on when making estimates of the cost\benefit of participating in programs compared to working. It is important to know the proportion of the population that is eligible for various subsidies (the denominator) compared to the proportion of the population that actually receives each of the subsidies (the numerator) in order to produce accurate estimates of program participation and an adequate cost-benefit analysis. The paper appears to include evidence that not all those are eligible actually participate in every program but the cost-benefit analysis does not take this probability of program use and participation into account.

The tables on family income by household members by marital status are interesting but the information needs to be summarized in a way that is easier for the reader to understand and follow the trends in the data from table to table. What is the relationship between marital status, number of household members, and income? How do these tables help us understand the eligible populations for the various programs? It is not clear from looking at all these panels what that relationship is between marital status, number of household members, and household income and that should be clarified.

The data seems to suggest that there are close to 1 million persons married and about 1.7 million that are single. At the bottom of page 9 the authors argue that 48% of the 1.7 million single persons in

Puerto Rico are women and they suggest that about 207,000 received incomes of less than \$5,000 a year. These are persons in extreme poverty that presumably qualify for various programs but that is not stated clearly in the report. **The authors then proceed to show a table with the number of single women by number of own children in the household and find that of the 867,322 single women about 742,620 do not have any own children. This suggests that according to the author's data 85.6% of single women in Puerto Rico not have any own children in the household.** This is quite relevant for understanding the prevalence of single motherhood in Puerto Rico and for understanding the proportion of the population that will be eligible for TANF and other related programs mentioned in the report that focus on families with young children (such as WIC and Head Start). Again, there is a need to be clear on what proportion of the population of single women are actually eligible for the various subsidies and programs that are mentioned in the report and what proportion actually receive them.

It is critical to stress that while the demographic narrative is interesting, it is somewhat confusing to try to understand what percent of the population is eligible for the different types of programs based on their characteristics and, more importantly, what proportion of the eligible population is actually enrolled and, in fact, receiving subsidies from the various programs. Information on actual take-up rates and program participation is critical to understanding the actual trade-offs between “welfare participation” and work.

Section III of the report provides a detailed analysis of main eligibility criteria for the various programs including PAN, section 8, WIC, TANF, Mi Salud (Health Plan), telephone, water, and electricity subsidies. The data presented in the section discusses some basic eligibility criteria and includes tables on the various income thresholds for the different programs and estimates of what look like the maximum payments allowed for recipients in each of the programs. The TANF benefit estimates on page 14, for example, presents estimates of payments under three different need scenarios and family sizes. This section does not include information on the actual proportion of the population that is eligible for each subsidy and the proportion of the population that actually receives each subsidy.

It is important to note that eligibility for their PAN program and for the health program (Mi Salud) allow for some family income which needs to be taken into account when evaluating the cost\benefits of participating in the programs versus working. It is not an “all or nothing” proposition as many families that receive some work income are also eligible for PAN and Mi Salud. Some portion of the subsidy is retained even if some income is generated and the report does not acknowledge or incorporate that.

The next section IV of the report focuses on estimating how much a minimum wage worker in Puerto Rico would earn under a part-time scenario and a full-time scenario. This section is relatively clear but, again, the earnings estimates from work do not incorporate the fact that some subsidies remain even after some work income is generated. There are households where all the income comes from aid, there are households where all the income comes from work and related (and receive no subsidies), and there are households that have work related income **and also receive some subsidies** and the estimates in this report, particularly the table on page 25, do not account for this.

Section V of the report tries to engage in a quantitative analysis of benefits compared to the potential income received from work.

Table of the top of page 21 presents some estimates of the monthly benefit by household size of the family receiving subsidies from the PAN program, section 8, the health subsidy program (Mi Salud), telephone, electricity, and water subsidy. It presents the total benefits estimated for households with one and up to 8 persons.

Section VI presents the quantitative analysis comparing a family working full or part-time at the minimum wage of \$7.25 per hour. The authors argue that their estimate of subsidies received is a conservative estimate because they do not include all of the programs that a family could receive and particularly mentions the WIC program and the Pell grants. These two programs are received by families and individuals with particular characteristics and under particular circumstances including pregnant women (or with young children) or college students. Rather than speculating that some families could also receive these subsidies, the study could have provided an estimate of the proportion of the population in each of those two categories (low income college students and women with children under 1, 2 or 3 years of age) and included those numbers in the estimates for the relevant households. It is also debatable whether the Pell Grant program can be considered “welfare” in any meaningful sense.

The first scenario that the paper presents is a scenario where the person receives some subsidies but not the TANF program or section 8 and compares estimated subsidies with earnings from part-time work. It finds that for one and two person households working part-time yields more than relying on subsidies.

Adding the TANF subsidies (as estimated in the paper) and section 8 subsidies in table 2 on page 24 the authors suggest that there is an advantage of receiving all subsidies over working part-time. Again, these estimates do not account for the fact that some subsidies remain with part-time work.

Comparing subsidies without the TANF program and section 8 compared to full-time earnings in table 1 on page 25 suggest that full-time earnings are a considerable advantage over partial subsidies.

The key table in the paper is table 2 on page 25 that compares total subsidies, including what this study estimates of the value of TANF and section 8 benefits, compared to the estimates of full-time earnings for households of various sizes.

The table would appear to show that a family with one member working full-time would earn \$1,159 and a family of three persons would also earn \$1,159 and if a family of three received all of the subsidies including TANF and section 8 they could receive \$1,743 per month in subsidies and benefits and that appears to be an advantage of \$585 over full time minimum wage work. These were the numbers that were used in the “Krueger Report” to argue that there was an “advantage of welfare over work.”

## Beneficios de Personas Elegibles al TANF vs. el Salario mí...

tiempo completo cuando la familia alcanza los dos (2) miembros.

Tabla 2:

Miembros en el hogar	Estimado de Ayudas			Total Ayudas Económicas	Estimado de Salario Mínimo a Tiempo Completo	Diferencia
	Económicas	TANF	Sección 8			
1	\$296	\$166	\$409	\$871	\$1,159	\$288
2	\$556	\$290	\$409	\$1,255	\$1,159	\$96
3	\$829	\$414	\$500	\$1,743	\$1,159	\$585
4	\$924	\$538	\$500	\$1,962	\$1,159	\$804
5	\$1,013	\$662	\$679	\$2,354	\$1,159	\$1,196
6	\$1,113	\$786	\$679	\$2,578	\$1,159	\$1,420
7	\$1,193	\$910	\$780	\$2,883	\$1,159	\$1,725
8	\$1,290	\$1,034	\$780	\$3,104	\$1,159	\$1,946

PUERTO RICO – A WAY FORWARD

- Workers are disinclined to take up jobs because the welfare system provides generous benefits that often exceed what minimum wage employment yields; one estimate shows that a household of three eligible for food stamps, AFDC, Medicaid and utilities subsidies could receive \$1,743 per month – as compared to a minimum wage earner's take-home earnings of \$1,159.

The result of all of the above is massive underutilization of labor, foregone output, and waning competitiveness.

There are several challenges with the numbers in this table 2 on page 25 of the ABC Report.

- The table assumes that all households use all subsidies. Data presented in report shows not all eligible persons use health (Mi Salud) or housing subsidies, for example. The report needs to factor the probability of participation and take-up rates into the estimates of the value of subsidies over work. Does the report include any data on what proportion of households of different sizes that actually receive all the mentioned subsidies?
- The estimates in the table assume everyone gets the maximum potential payment. This is in theory and we need to examine actual program data to see what are the actual benefit levels by household size. Very few cases get maximum potential benefit in all the programs because funds are capped.
- Assumes a household labor supply of one person that is the same (and unaffected) by household size or the age\gender composition of the household. Larger households, depending on the age of members, are likely to have higher labor supply and it is unreasonable to assume that a household with 8 members will have the same labor supply as a household with one member. Estimating earning for just one member in large households lowers the estimates of earned income and increases the relative value of the subsidies. The report should look at actual household composition, household size, and labor supply data in order to make more realistic estimates of potential earnings for households of different sizes and composition.

4. The estimates do not account for fact that many households would still be eligible for Mi Salud and PAN subsidies if earning at minimum wage or earning below poverty level. The estimates assume either all subsidy income or all work income but the authors do not contemplate or analyze the cost\benefit calculation for households that receive some subsidies and also generate some income.
5. The report does not provide nuanced estimates of cost\benefit analysis for households with different composition and various mixes of adults and children. A household of three persons could have one adult and two children, two adults and one child, or three adults, and the eligibility for benefits and subsidies will be different for different types of households. The report does not take this into account.

Below, I present two corrections to the estimates presented in the report.

1. First, I corrected the numbers for TANF payments based on actual TANF Data for June 2015 on average benefit levels by household size. The column labeled "TANF real" is the actual average amount of TANF benefits by household size.
2. Second, I make some adjustments to the labor supply. Households with up to three members are left with one worker. Households with 4 members have a 1.25 labor supply. Households with 5 and 6 members have 1.5 labor supply, and households with 7 and 8 members have labor supply of 2.0. Changes in labor supply assumptions for larger households follow empirical trends in labor supply by household size.
3. I am so added data on TANF participation from the case load data for June 2015. In June 2015, there were 65,733 TANF cases out of over 1.6 million persons in poverty (estimated using 2013 PRCS data).

## Adjusted TANF Payment and Work Supply Estimates

↑ Adjusted TANF
↑ Adjusted work supply
↑ Adjusted difference

8/13/2015

Dr. Hector Cordero-Guzman  
(hcordero@aol.com)

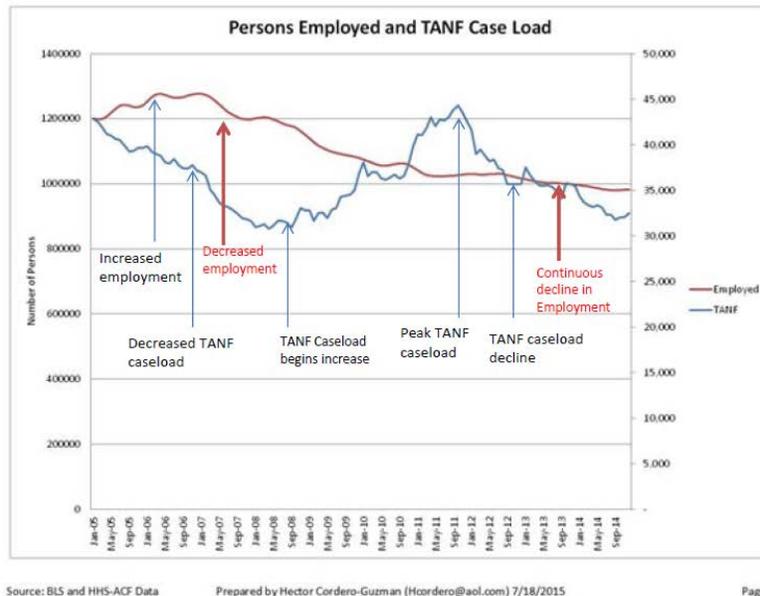

24

- Making adjustments using actual TANF benefit amounts and modifying the labor supply estimates for larger households reduces the purported advantages of “welfare” (subsidies) over work significantly. It is also important to keep in mind that not all those eligible receive aid and that not all aid ends with paid work.
- Data shows 71% of cases are 1 or 2 person households (where the economic advantage of work over program benefits are largest).
- 16.7% of all TANF cases (or close to 10,876 cases) are in 3 person households where there is presumably some advantage of program participation over work.
- For discussion purposes, 3 person households are assumed to include one female adult and two minor children. For those limited number of households, there may be a small advantage of program participation over work. There should be discussion about the costs and desirability, from a social and public policy perspective, of reducing benefits for low income women with small children.
- If we assume a 3 person household with two working adults and one child, the advantages of work over welfare are clear [ $\$1,159 \times 2 = \$2318$  compared to between  $\$1,539$  (my estimate) and  $\$1,743$  (the report’s estimate) of the value of benefits].
- The revised data in the report, particularly when compared to the actual case-load data by household size, suggest that for 71% of TANF cases the value of benefits and subsidies is lower than what they could receive from work. For close to 27% of TANF cases in households between 3-6 members there could be (assuming the household can get all subsidies) some advantage of

the value of subsidies over full time minimum wage work. Note that this includes less than 20,000 persons out of an estimated poverty population of 1.6 million persons.

Some additional observations on the relationship between TANF caseload and employment in Puerto Rico:

- Looking at the historical trend of employment levels and TANF caseloads in Puerto Rico helps clarify the relationship between employment and TANF participation.
- The data show that as employment grew, TANF participation declined but about a year after employment started to collapse there was an increase in TANF use until the rate of employment decline leveled off--and time limits started to kick in--starting a reduction in the TANF case load.
- The timing of the data is clear that changes in the TANF caseload follow changes in employment and not the other way around. Declines in employment drive TANF use and it is clear that TANF use is not what drives employment levels in Puerto Rico.

8/13/2015

Dr. Hector Cordero-Guzman  
(hcordero@aol.com)

39

The **ABC Consulting report: “Beneficios de las Personas Elegibles al Tanf Vs. Escenario de Salario Mínimo Federal”** concludes with a series of recommendations. My sense is that the comments in the first two paragraphs of the recommendations are not sustained by the data. The employment collapse in Puerto Rico is not due to TANF or welfare programs and there is abundant labor supply and people willing to work in Puerto Rico with an unemployment rate consistently over 10 percent and over 100,000 people looking for work. As was stated, the employment pattern in the table above is not explained by patters of use of the TANF program.

The third and fourth paragraphs of the recommendations on a work credit through the tax code seem sensible as does the recommendation that the head start program adjust to work schedules.

The list of recommendations offered on TANF about re-design are not clearly spelled out and the reader has no idea what the authors mean by 'Re-evaluate and re-design the TANF program.' In what ways? How? Exactly why?

Many of the recommendations focus on Head Start which is not a program that was analyzed in the report. It is not clear where many of these recommendations come from and what they have to do with the materials presented in the report.

In sum, this report is interesting but has a number of challenges that compromise its conclusions:

1. The demographic analysis is confusing and limited.
2. It does not present precise estimates and information on the size and composition eligible populations by program including TANF, the PAN program, section 8, the health subsidy program (Mi Salud), telephone, electricity, and water subsidy.
3. It does not present information on take-up rates and access to the various programs and subsidies [including TANF, the PAN program, section 8, the health subsidy program (Mi Salud), telephone, electricity, and water subsidy] and the proportion of eligible persons that actually receive each subsidy. In fact, the only table that helps us understand eligibility and access is on health insurance (p.7) and it provides evidence that not all eligible persons receive the health care subsidy (Mi Salud).
4. The report does not distinguish between the labor supply of men and the labor supply of women and how they are affected by access to subsidies and household composition and sizes. The report also does not consider how disability status impacts both program participation (particularly in TANF) and work status.
5. Some of the subsidy estimates included and used in the report are theoretical and therefore inflated and not derived from actual program data. Actual TANF program data shows that average TANF payments are lower than those used in this report.

The study provides a lot of valuable information and a very useful framework that should be discussed and can be revised, updated, and improved but, as is, the report is fine for academic discussion but without an analysis of the actual population eligible and participating in the various programs and subsidies considered, and without more accurate estimates of the size and availability of the subsidies to the actual population, it is of limited use and applicability for public policy making.

**Congressional Task Force on Economic Growth in Puerto Rico**  
**Report to the House and Senate**

**Introduction**

On June 30, 2016, the Puerto Rico Oversight, Management, and Economic Stability Act, or “PROMESA,” was enacted into law as [Public Law 114-187](#). Section 409 of PROMESA established an eight-member “Congressional Task Force on Economic Growth in Puerto Rico” (“Task Force”). In July 2016, in accordance with Section 409(b), two members of the Task Force were appointed by House Speaker Paul Ryan, two members were appointed by House Minority Leader Nancy Pelosi, two members were appointed by Senate Majority Leader Mitch McConnell, and two members were appointed by Senate Minority Leader Harry Reid.

The members appointed are as follows:

- Representative Sean Duffy (R-Wisconsin), appointed by House Speaker Paul Ryan;
- Representative Tom MacArthur (R-New Jersey), appointed by House Speaker Paul Ryan;
- Resident Commissioner Pedro Pierluisi (D-Puerto Rico), appointed by House Minority Leader Nancy Pelosi;
- Representative Nydia Velázquez (D-New York), appointed by House Minority Leader Nancy Pelosi;
- Senator Orrin Hatch (R-Utah), appointed by Senate Majority Leader Mitch McConnell;
- Senator Marco Rubio (R-Florida), appointed by Senate Majority Leader Mitch McConnell;
- Senator Robert Menendez (D-New Jersey), appointed by Senate Minority Leader Harry Reid; and
- Senator Bill Nelson (D-Florida), appointed by Senate Minority Leader Harry Reid.

Pursuant to Section 409(d), Speaker Ryan designated Senator Hatch to serve as chairman of the Task Force.

Section 409(f) required the Task Force to provide a “status update” to the House and Senate between September 1, 2016 and September 15, 2016, containing “information the Task Force has collected” and “a discussion on matters the chairman of the Task Force deems urgent for consideration by Congress.” On September 15<sup>th</sup>, the Task Force published this status update in both [English](#) and [Spanish](#).

Section 409(g) requires the Task Force to produce a report, by December 31, 2016, regarding:

- “(1) impediments in current Federal law and programs to economic growth in Puerto Rico including equitable access to Federal health care programs;

(2) recommended changes to Federal law and programs that, if adopted, would serve to spur sustainable long-term economic growth, job creation, reduce child poverty, and attract investment in Puerto Rico;

(3) the economic effect of Administrative Order No. 346 of the Department of Health of the Commonwealth of Puerto Rico (relating to natural products, natural supplements, and dietary supplements) or any successor or substantially similar order, rule, or guidance of the Commonwealth of Puerto Rico; and

(4) additional information the Task Force deems appropriate.”

This document is the report mandated by Section 409(g). Having issued this report, the Task Force now terminates, consistent with Section 409(l).

## 1. Sources of Information

To prepare this report, the Task Force obtained information from various sources.

First, on August 4, 2016, the Task Force issued a [press release](#) announcing the creation of an email portal and encouraged stakeholders to submit their recommendations to this portal. The Task Force initially announced a deadline of September 2<sup>nd</sup> for submissions to the portal. However, on September 6<sup>th</sup>, the Task Force issued a [press release](#) extending the deadline until October 14<sup>th</sup> in order to ensure that stakeholders had sufficient opportunity to provide input.

The Task Force received approximately 450 submissions via the email portal. **Appendix 1** of this report contains an alphabetized table that lists the individuals and organizations that made written submissions, including hyperlinks to each submission and any attachments. Submissions made after the October 14<sup>th</sup> deadline are included in the table, but marked as late.

The Task Force is grateful to the individuals and organizations who took time to provide submissions to the email portal, as well as to those who visited Capitol Hill—many of them traveling from Puerto Rico—to expand upon their submission. It is clear that there are many people who care deeply about Puerto Rico, who want the island to prosper, and who have thoughtful suggestions for how it can overcome its challenges and reach its potential. In preparing this report, and crafting its recommendations, the Task Force was guided by its own appreciation for Puerto Rico and desire to see it succeed.

The Task Force does note that many submissions to the email portal offer recommendations that are local rather than federal in nature, and would therefore be more properly addressed to—and

by—the government of Puerto Rico than to—and by—Congress or federal executive branch agencies. Accordingly, the Task Force recommends that Puerto Rico’s elected and appointed leaders, as well as the members and staff of the Financial Oversight and Management Board (“Oversight Board”) established by Section 101 of PROMESA, carefully review the submissions in Appendix 1.

Second, the Task Force organized a series of formal staff-level briefings with federal agencies. Here is a list of those briefings:

- August 12: Federal Reserve Bank of New York
- September 20: U.S. Small Business Administration
- September 30: U.S. Department of Energy
- October 4: Community Development Financial Institutions Fund (U.S. Department of the Treasury)
- October 7: U.S. Department of Health and Human Services
- October 11: U.S. Department of the Treasury
- October 14: U.S. Environmental Protection Agency
- October 21: U.S. Census Bureau (U.S. Department of Commerce), Bureau of Labor Statistics (U.S. Department of Labor), and National Agricultural Statistics Service (U.S. Department of Agriculture)
- October 28: Bureau of Economic Analysis (U.S. Department of Commerce), Economic Development Administration (U.S. Department of Commerce), International Trade Administration (U.S. Department of Commerce), and Minority Business Development Agency (U.S. Department of Commerce)

Third, the Task Force consulted with non-partisan congressional support organizations. Specifically, it consulted with analysts at the Congressional Research Service (CRS) about a wide range of federal policy matters pertaining to Puerto Rico, and with analysts at the Congressional Budget Office (CBO) and the Joint Committee on Taxation (JCT) about the budgetary impact of spending and revenue proposals related to Puerto Rico. The Task Force also reviewed reports written by CRS, JCT, and the U.S. Government Accountability Office (GAO) regarding Puerto Rico. Since CRS does not release its reports to the public, the Task Force exercised its right to make the relevant CRS products public, and has linked to these products in this report.

Fourth, Section 409(j) of PROMESA required the Task Force to consult with the Puerto Rico Legislative Assembly, the Puerto Rico Department of Economic Development and Commerce (DDEC, in its Spanish-language acronym), and the private sector of Puerto Rico—and the Task Force has fulfilled that mandate.

Finally, the Task Force staff held a conference call with the Secretary of the Puerto Rico Department of Health, Dr. Ana Rius Armendariz, to discuss Administrative Order 346, issued by the Department on February 9, 2016.

## **2. Organization of Report**

This report is organized as follows. Following this “Introduction” section, there is a “Background” section that includes two subsections. Subsection 1 presents a brief overview of the economic, fiscal and demographic situation in Puerto Rico. Subsection 2 provides information on Puerto Rico’s treatment under federal programs. As explained in Subsection 2, in an effort to inform policymakers and the public, the Task Force has prepared a table of approximately 40 federal programs that allocate resources to states and territories according to a formula, where that formula treats Puerto Rico differently than the states. That table appears in **Appendix 2**. The “Background” section is followed by the “Discussion and Recommendations” section, which contains the Task Force’s recommendations to Congress, federal agencies, and the government of Puerto Rico. Recommendations are organized by subject matter area or by federal agency. Since Section 409(g) of PROMESA makes clear that the Task Force should focus on federal laws and programs, recommendations to the government of Puerto Rico are purposefully limited in scope, confined to areas where there is a strong federal nexus.

Section 409(h) of PROMESA instructs the Task Force that, “[t]o the greatest extent practicable,” the Task Force report “shall reflect the shared views of all eight Members.” Consistent with that directive, where the Task Force does make a specific recommendation, that recommendation reflects a consensus among the members. Section 409(h) authorizes a member, or multiple members, to publish dissenting views, but no member has elected to do so.

The Task Force notes that a number of its recommendations also apply to the four other U.S. territories—American Samoa, Guam, the Northern Mariana Islands, and the United States Virgin Islands, which (to varying degrees) face considerable challenges of their own.

## **3. Statement of Purpose**

The 3.4 million U.S. citizens in Puerto Rico confront significant economic, financial, and social challenges. A review of Puerto Rico’s history demonstrates that these challenges are enduring, not transitory. In recent years, the challenges have grown more severe, and have attracted more attention from policymakers and the public.

The Task Force is of the view that Puerto Rico’s best days lie before it, not behind it. It is a fact that residents of Puerto Rico, who have greatly contributed to this nation in times of both war and peace, are as talented and as hard-working as their fellow citizens living anywhere else in the

country.<sup>1</sup> It is also a fact that they have not always been well served by their leaders in San Juan or in Washington, DC. The Task Force believes that the people of Puerto Rico deserve a strong, stable and diversified economy. Judging from the written submissions that the Task Force received through the email portal, there is no shortage of important economic development work being performed or planned in Puerto Rico.<sup>2</sup>

The Task Force hopes this report will contribute to a brighter future in Puerto Rico. At the same time, the Task Force offers a word of caution to those expecting a “federal solution” to each of Puerto Rico’s problems. There are certain challenges in Puerto Rico—such as an outdated energy system, a troubled K-12 public education system, and inefficiencies in various other sectors—that must be tackled first and foremost by the government of Puerto Rico and the private sector.

The members of the Task Force have worked across party lines to identify steps that can be taken to help Puerto Rico’s economy stabilize and grow. The Task Force hopes that its work will serve as a platform for continued bipartisan efforts to support the American citizens in Puerto Rico.

## **Background**

### **1. Overview of Economic, Fiscal and Demographic Situation in Puerto Rico**

Individual members of the Task Force have a range of views on PROMESA itself, which authorizes public entities in Puerto Rico to restructure their debts pursuant to a process prescribed by law, and establishes a seven-member Oversight Board to temporarily supervise or otherwise be involved in decision-making by the government of Puerto Rico on budgetary, fiscal, and debt restructuring matters.<sup>3</sup> However, the members of the Task Force concur that

---

<sup>1</sup> For example, the director of the Minority Business Development Agency within the U.S. Department of Commerce informed the Task Force that an executive from the world’s largest aerospace company told her that many of the company’s best engineers are recruited from Puerto Rico, which is home to one of the leading engineering schools in the nation (the University of Puerto Rico at Mayagüez). Similarly, representatives of biotechnology firms operating in Puerto Rico regularly cite the productivity and technical proficiency of the locally-educated, locally-trained workforce.

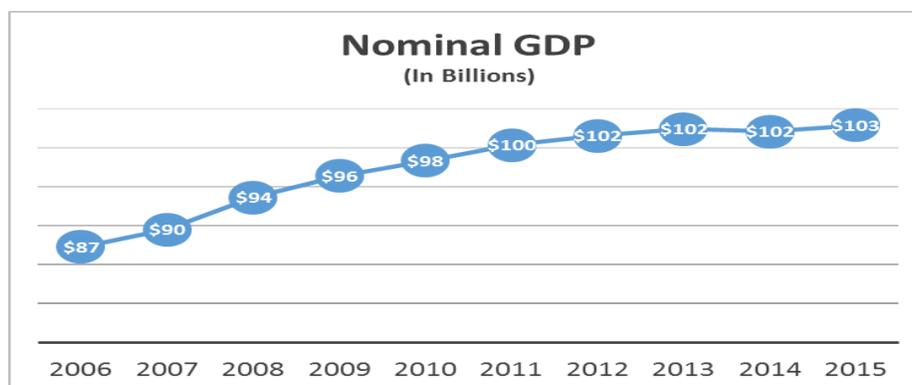

<sup>2</sup> For a sampling of many possible examples, *see* Appendix 2 for submissions from Paralle118; the Puerto Rico Science, Technology, and Research Trust; the Aeronautical and Aerospace Institute of Puerto Rico; the Puerto Rico Chapter of the Association of Information Technology Professionals; the Foundation for Puerto Rico; Non-Profit Community Service Organizations in Puerto Rico (*Red de Fundaciones de Puerto Rico* and *Una Sola Voz*); the Puerto Rico Community Foundation; the Puerto Rico Information Technology Cluster; and the Youth Development Institute.

<sup>3</sup> For an overview of PROMESA, see D. Andrew Austin et al, [The Puerto Rico Oversight, Management, and Economic Stability Act](#), Congressional Research Service, July 1, 2016.

PROMESA is a product of the grave economic, fiscal and demographic situation in Puerto Rico. The crisis has multiple root causes, and a discussion of those causes is beyond the scope of this report. Nevertheless, it is clear that Puerto Rico faces formidable challenges.

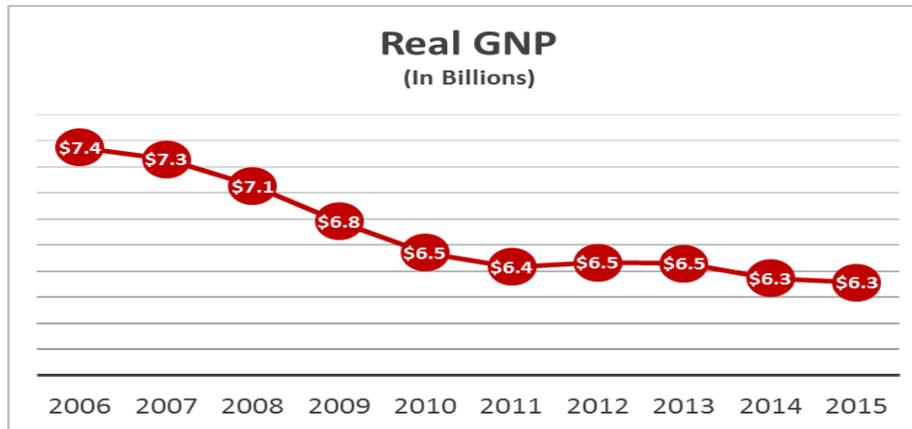

The Task Force will summarize current conditions on the island with a series of bullet points. Because Puerto Rico is a U.S. jurisdiction, the 50 states and the District of Columbia serve as an appropriate point of comparison. As discussed later in the report, many federal statistical programs that collect and publish state-by-state economic data do not collect and publish data for Puerto Rico. Likewise, economic data produced by the government of Puerto Rico are often unreliable or untimely, although efforts are underway to make improvements in this area. Accordingly, the Task Force was not able to obtain as much information about Puerto Rico's economy and government finances as it would have liked. Nevertheless, sufficient information exists to form a reasonably accurate picture of the territory's economy.

- Puerto Rico's economy is typically measured using gross national product (GNP), rather than gross domestic product (GDP). Puerto Rico's GNP is calculated by the Puerto Rico Planning Board (*Junta de Planificación de Puerto Rico*). According to the [Statistical Appendix](#) to the Puerto Rico Planning Board's Fiscal Year 2015 Economic Report to the Governor and Legislative Assembly, Puerto Rico's real GNP—measured in constant 1954 dollars—contracted every year between Fiscal Year 2006 (\$7.4 billion) and Fiscal Year 2015 (\$6.3 billion), except for one year of slight growth between Fiscal Year 2011 (\$6.43 billion) and Fiscal Year 2012 (\$6.47 billion).<sup>4</sup> In nominal terms, Puerto Rico's GNP increased from \$57.9 billion in Fiscal Year 2006 to \$68.5 billion in Fiscal Year 2015, and its GDP increased from \$87.3 billion in Fiscal Year 2006 to \$102.9 billion in Fiscal Year 2015.<sup>5</sup>

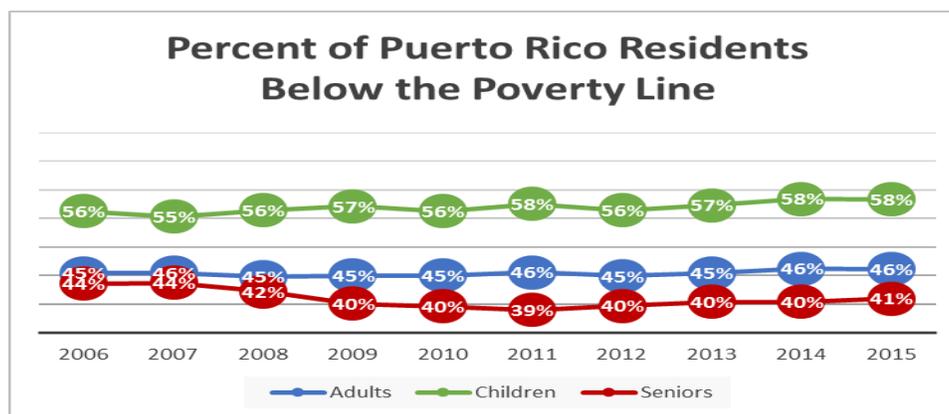

<sup>4</sup> See [Statistical Appendix](#), page A-6.

<sup>5</sup> See [Statistical Appendix](#), page A-1.

- The Puerto Rico Fiscal Agency and Financial Advisory Authority (FAFAA), formerly the Puerto Rico Government Development Bank (GDB), maintains an [Economic Activity Index](#) (EAI) that consists of four factors: (1) payroll employment, (2) electric power generation, (3) cement sales, and (4) gasoline consumption. Between August 2005 and August 2016, the EAI fell by approximately 20 percent, from nearly 160.0 to 124.1.
- According to the U.S. Census Bureau’s 2015 Puerto Rico Community Survey and the 2015 American Community Survey, 46.1 percent of Puerto Rico residents live below the federal poverty level, compared to a national average of 14.7 percent.<sup>6</sup> Of Puerto Rico residents under age 18, 58.3 percent live below the federal poverty level, compared to a national average of 20.7 percent. Of children in Puerto Rico under age 5, 63.7 percent live below the federal poverty level, compared to a national average of 22.8 percent. Of Puerto Rico seniors age 65 and older, 41 percent live below the federal poverty level, compared to about 9 percent nationally.

<sup>6</sup> To corroborate the Census Bureau data referenced in this report, readers can use the “Advanced Search” function on American FactFinder, available [here](#).

- According to the 2015 Puerto Rico Community Survey, median household income in Puerto Rico is \$18,626, with 83.3 percent of island households earning less than \$50,000 per year. In the states and the District of Columbia, median household income is [\\$56,515](#). The state with the lowest median household income is Mississippi, at \$40,593. According to May 2015 data from the Bureau of Labor Statistics (BLS) within the U.S. Department of Labor, the median hourly wage for workers in Puerto Rico is [\\$9.61](#), while the median hourly wage in the states and the District of Columbia is [\\$17.40](#).
- According to [BLS](#), Puerto Rico’s unemployment rate in October 2016 was 12.1 percent, while the national unemployment rate was 4.9 percent and the state with the highest unemployment rate was Alaska at 6.8 percent. According to historical state-by-state BLS unemployment [data](#), which have been published since January 1976, Puerto Rico’s unemployment rate has always been several percentage points or more higher than the state with the highest unemployment rate. From January 1976 to December 1989, Puerto Rico’s average unemployment rate was about 19 percent. From January 1990 to December 1999, it was about 14 percent. From January 2000 to December 2009, it was about 12 percent. And from January 2010 to October 2016, it was about 14 percent.
- According to [BLS](#), the number of persons employed in Puerto Rico peaked in December 2006 at 1,277,559. In October 2016, that figure was 987,606—a 23 percent reduction.<sup>7</sup> According to the Puerto Rico Planning Board, even when employment was at its peak in Puerto Rico in 2006, the labor force participation rate was 48.6 percent.<sup>8</sup> In 2015, the labor force participation rate was 39.9 percent.<sup>9</sup> According to [BLS](#), the national labor force participation rate is approximately 63 percent.
- Puerto Rico has a large informal or “underground” economy, which refers to activities and income that are partially or fully outside of government regulation (e.g., minimum wage laws and workplace safety laws) and taxation (e.g., income tax and employment tax). Although the size of Puerto Rico’s informal economy is, by definition, difficult to measure with precision, estimates about its size generally range from about 15 percent of GNP to about [20 percent](#) of GNP. The existence of a large informal economy has a number of negative effects, chief among them the erosion of Puerto Rico’s individual and corporate tax base,

---

<sup>7</sup> The employment decline in this period—23 percent—was significantly larger than the population decline—about 8 percent—during the same period.

<sup>8</sup> The labor force participation rate measures the labor force—the sum of employed individuals and unemployed individuals who do not have a job and are looking for work—as a percentage of the non-institutionalized population age 16 and older.

<sup>9</sup> See [Statistical Appendix](#), page A-62.

which deprives the government of revenue needed to finance operations, provide services, and meet debt obligations.

- According to the proposed [Fiscal Plan](#) and [Appendix](#) presented to the Oversight Board by the government of Puerto Rico on October 14, 2016, Puerto Rico’s aggregate public sector debt stock is \$68.7 billion, which is roughly equal to Puerto Rico’s nominal GNP. Puerto Rico’s public sector debt as a percentage of GNP grew steadily starting in Fiscal Year 2001, when it was about 60 percent of GNP. In 2005, it was about 70 percent of GNP. In 2009, it was about 90 percent of GNP. By 2013, it was about 102 percent of GNP.<sup>10</sup> According to a 2014 [report](#) published by the Federal Reserve Bank of New York (FRBNY)—which oversees the Second District of the Federal Reserve System, which encompasses Puerto Rico—Puerto Rico’s public debt to GNP ratio is “far higher” than the public debt to GDP ratio of any state.<sup>11</sup>
- According to the [Independent Auditors Report](#) accompanying the government of Puerto Rico’s audited financial statements for Fiscal Year 2013-Fiscal Year 2014, which were not released until July 1, 2016, the main public pension systems in Puerto Rico—the Puerto Rico Teachers Retirement System (TRS), the Puerto Rico Government Employees Retirement System (ERS), and the Puerto Rico Judiciary Retirement System (JRS)—“are at risk of becoming insolvent.”
  - As of June 30, 2015, the [TRS](#) reported a net pension liability of \$15.0 billion with a “funded ratio”—the value of assets as a percentage of total pension liability—of 8.1 percent.
  - As of June 30, 2015, the [ERS](#)—which provides retirement benefits to former central government employees, municipal government employees, and employees of all but one public corporation—is in a *negative* funded position, when assets are considered net of pension obligation bond proceeds. ERS reported a net pension liability of \$33.2 billion with a funded ratio of -1.8 percent.

---

<sup>10</sup> See [Testimony](#) of Sergio M. Marxuach, Center for a New Economy, Hearing on “Financial and Economic Challenges in Puerto Rico,” Senate Committee on Finance, September 29, 2015, at page 25; Carlos A. Colón De Armas, Submission to Congressional Task Force on Economic Growth in Puerto Rico, at page 12; D. Andrew Austin, [Puerto Rico’s Current Fiscal Challenges: In Brief](#), Congressional Research Service, June 3, 2016, at page 10.

<sup>11</sup> See Federal Reserve Bank of New York, [An Update on the Competitiveness of Puerto Rico’s Economy](#), July 31, 2014, at page 16.

- As of June 30, 2015, the [JRS](#) net pension liability was \$542.6 million, with a funded ratio of 7.3 percent.

(\$ thousands)	ERS 2015	TRS 2015	JRS 2015
<b>Total Pension Liability (TPL)</b>	32,669,162	16,307,731	585,312
<b>Actuarial Value of Assets (net)</b>	(578,633)	1,313,148	42,729
<b>Net Pension Liability</b>	33,247,795	14,994,583	542,583
<b>Net Position as % of TPL</b>	-1.8%	8.1%	7.3%

- According to the U.S. Census Bureau, Puerto Rico’s population was [3,808,610](#) in 2000. The island’s population peaked in 2004, at [3,826,878](#) and has decreased every year since then. Puerto Rico’s population in 2015 stood at [3,474,182](#). From the 2004 peak, that is a loss of 352,696 persons, or 9.2 percent. Researchers at the FRBNY have called the population loss in the territory “staggering” and published multiple reports examining its nature and implications.<sup>12</sup> According to the 2015 American Community Survey, there are now 5.4 million individuals of Puerto Rican birth or descent living in the 50 states and the District of Columbia, up from 3.8 million in 2005. Of those 5.4 million, 1.7 million were born in Puerto Rico, up from 1.3 million in 2005.
- According to the [FRBNY](#), the mortgage delinquency rate (the percentage of mortgage balances that are more than 90 days due) in both Puerto Rico and the United States as a whole rose sharply between 2005 and 2009. While the delinquency rate in the United States has since fallen to about 2 percent, the delinquency rate in Puerto Rico—which peaked in 2010 at 8 percent—“has remained stubbornly high, at 7 percent.” The FRBNY notes that “[s]erious delinquency rates on other forms of debt in Puerto Rico also remain well above those on the mainland.”
- FRBNY researchers have identified a number of challenges facing Puerto Rico—such as the need to improve labor market opportunities, develop human capital, lower the costs of doing business, mobilize financing for business development and growth, and reduce dependence on the “shrinking” pharmaceutical industry—and presented a series of corresponding policy recommendations.<sup>13</sup> While the Task Force does not necessarily endorse all of the policy

<sup>12</sup> See, e.g., [Migration in Puerto Rico: Is There a Brain Drain?](#), Liberty Street Economics, August 9, 2016; [Population Lost: Puerto Rico’s Troubling Out-Migration](#), Liberty Street Economics, April 13, 2015; [The Causes and Consequences of Puerto Rico’s Declining Population](#), Current Issues in Economics and Finance (Volume 20, Number 4; 2014).

<sup>13</sup> See, e.g., Federal Reserve Bank of New York, [A Report on the Competitiveness of Puerto Rico’s Economy](#), June 29, 2012; Federal Reserve Bank of New York, [An Update on the Competitiveness of Puerto Rico’s Economy](#), July 31, 2014; William C. Dudley, President and Chief Executive Officer,

recommendations of the FRBNY researchers, it does believe they are worthy of study and debate.

- A decade ago, researchers from across the political spectrum, organized by the Brookings Institution and the Puerto Rico-based Center for the New Economy (CNE), authored a series of academic papers on obstacles to economic growth in Puerto Rico, and policies that could help overcome those obstacles, and these papers were compiled in a 2006 book.<sup>14</sup> Many of the challenges identified at the time remain challenges today, and some have become more severe. Corrective actions that could have been taken at the time were not, in part because of Puerto Rico’s excessive reliance on debt financing. While the Task Force does not necessarily endorse all of the policy recommendations contained in the Brookings-CNE book, it does believe that the book remains a useful tool for policymakers thinking about Puerto Rico.

## 2. Puerto Rico’s Treatment Under Federal Programs

The U.S. Supreme Court has [held](#) that the Territory Clause of the U.S. Constitution (Article IV, Section 3, Clause 2) authorizes Congress to treat territories differently than states under federal laws and programs as long as there is a “rational basis” for the differential treatment. Congress generally determines whether Puerto Rico and the four other territories are eligible for federal programs on a case-by-case basis, and defines any differential treatment in law. Puerto Rico is treated the same as the states under certain federal programs, and differently than the states under other federal programs.

Federal law provides that a bona fide resident of Puerto Rico is generally not required to pay federal tax on income he or she earns in Puerto Rico (except for income earned by the roughly [9,400](#) federal government employees on the island), and that a corporation organized in Puerto Rico is generally treated as a foreign corporation for U.S. tax purposes, and therefore is generally not required to pay federal tax on its Puerto Rico-source income.<sup>15</sup>

---

Federal Reserve Bank of New York, “[Opportunities for Economic Growth in Puerto Rico](#),” November 29, 2016.

<sup>14</sup> See [The Economy of Puerto Rico: Restoring Growth](#), edited by Susan M. Collins, Barry P. Bosworth, and Miguel A. Soto-Class (CNE/Brookings 2006).

<sup>15</sup> For information on Puerto Rico’s treatment under federal tax law, see [Federal Tax Law And Issues Related To The Commonwealth Of Puerto Rico](#), Joint Committee on Taxation, September 28, 2015 (JCX-132-15); [Puerto Rico, Information on How Statehood Would Potentially Affect Selected Federal Programs and Revenue Sources](#), Government Accountability Office, March 2014 (GAO-14-31); and Sean Lowry, [Tax Policy and U.S. Territories: Overview and Issues for Congress](#), Congressional Research Service, October 7, 2016.

In those instances when Congress does choose to treat Puerto Rico differently than the states under a particular federal assistance program that is funded by appropriations made from the general fund of the United States, Congress often relies, either explicitly or implicitly, on the argument that such differential treatment is warranted because individuals and businesses in Puerto Rico do not contribute federal income taxes into the general fund to the same degree and extent as their counterparts in the states.

The tax treatment of U.S. corporations operating in Puerto Rico is more complex. U.S. corporations are subject to federal income tax on their worldwide earnings. Generally, income earned by the active business operations of U.S. corporations in Puerto Rico is considered foreign-source income. Federal tax on active corporate income earned in Puerto Rico by foreign *subsidiaries* of U.S. corporations—known as controlled foreign corporations (CFCs)—can be deferred until these earnings are “repatriated” to the United States in the form of dividend distributions to the U.S. parent corporation. However, federal tax on the income earned by foreign *branches* of U.S. corporations is not deferrable. A foreign subsidiary is a legal entity separate from its parent company, while a foreign branch is an extension of a domestic company. Most, but not all, U.S. corporations with active business operations in Puerto Rico are organized as CFCs.

Federal law generally requires individuals and businesses in Puerto Rico to pay federal tax on income they earn outside of Puerto Rico, whether in the United States or in a foreign country. Federal law also requires employers and employees in Puerto Rico to pay all federal payroll taxes, which fund the Old Age, Survivors, and Disability Insurance program (Social Security), the Medicare hospital insurance program, and the federal unemployment compensation program. According to the 2015 [Internal Revenue Service Data Book](#), the IRS collected \$3.52 billion in federal taxes on individuals and businesses in Puerto Rico in Fiscal Year 2015.<sup>16</sup>

With the assistance of CRS, the Task Force has created a table of approximately 40 federal programs that allocate resources according to a formula, as distinct from programs that allocate resources on a competitive basis, under which Puerto Rico is treated differently than the states and, in certain cases, differently than other territories. The table, which appears in **Appendix 3**, is intended to be thorough but not exhaustive. It provides: (1) the name of the program; (2) the federal executive branch agency that administers the program; (3) the congressional committees in the Senate and the House with jurisdiction over the program; and (4) a description of Puerto Rico’s differential treatment under the program. The table also includes certain programs that allocate resources but do not fall within the commonly-understood definition of a formula-based program.

---

<sup>16</sup> See [Internal Revenue Service Data Book](#), at page 12, Table 5.

This table is intended solely to provide factual information to policymakers and the public. Reference to a program should not be interpreted to signify either support for or opposition to Puerto Rico's differential treatment under the program on the part of the Task Force. Later in the report, the Task Force will make recommendations pertaining to several of these programs.

With respect to federal programs that allocate resources on a competitive basis, rather than pursuant to a formula prescribed in law, the Task Force's informed judgment is that entities in Puerto Rico—whether it be the central government, municipal governments, for-profit firms, or non-profit organizations—tend to fare poorly relative to entities in other jurisdictions, and often do not apply for available funding or apply unsuccessfully. While there is no simple way to reverse this trend, the Task Force believes that steps should be taken by Puerto Rico-based entities to better familiarize themselves with competitive funding opportunities across the federal government, and that the government of Puerto Rico and federal agencies should enhance their respective efforts to provide these entities with information and technical assistance.

In addition, the Task Force is aware of numerous instances in which the government of Puerto Rico has received a formula-based or competitive grant from the federal government, but has not utilized all of that funding within the applicable time frame, thereby requiring the return of unused funding to the federal treasury. Although this problem is not unique to Puerto Rico, it does appear to be more pronounced on the island compared to other jurisdictions, based on information provided to the Task Force. The Task Force urges the government of Puerto Rico as a whole, and each Puerto Rico agency individually, to scrutinize its grant management system so as to reduce such funding reversions to the greatest extent possible. The Task Force further urges the government of Puerto Rico to make appropriate use of available federal support services in this area. Every federal grant dollar returned by the local government is a missed opportunity to assist the people of Puerto Rico.

## **Discussion and Recommendations**

### **1. Health Care**

Section 409(g)(1) of PROMESA requires the Task Force to make recommendations regarding impediments in current federal law and programs to economic growth in Puerto Rico, “including equitable access to federal health care programs.”

On October 7<sup>th</sup>, the Task Force held a staff-level briefing with officials from the U.S. Department of Health and Human Services (HHS). The Task Force also spoke to a wide range of stakeholders in Puerto Rico's health care community. In addition, numerous individuals and

organizations made submissions via the Task Force's email portal that discuss this topic. Finally, the Task Force consulted an analysis of the subject prepared by CRS.<sup>17</sup>

### **A. Medicaid**

The Task Force believes that the future financing of the Medicaid program in Puerto Rico is a serious and urgent issue facing federal policymakers attempting to address the territory's economic and social challenges.

Members of the Task Force have differing views regarding the proper role of the federal government in financing federal health programs in general and the Medicaid program in particular, as well as regarding the relative merits of the 2010 Patient Protection and Affordable Care Act (ACA; P.L. 111-148, as amended). However, Task Force members agree that, irrespective of these larger policy disagreements and the congressional debates they will continue to generate in the coming years, an equitable and sustainable legislative solution to the financing of Puerto Rico's Medicaid program should be enacted early in 2017.

Medicaid is a joint federal-state program that finances the delivery of medical services for low-income individuals. In Fiscal Year 2015, Medicaid (including the State Children's Health Insurance Program, or CHIP) is [estimated](#) to have provided health care services to 73 million individuals at a total cost of \$509 billion in federal and state expenditures.

Puerto Rico's Medicaid program, known locally as Mi Salud, has about 1.4 million enrollees, which is over 40 percent of the island's population, a higher proportion than the 50 states and the District of Columbia. Like numerous states, Puerto Rico uses a managed care system to deliver Medicaid services. The territory's Medicaid agency contracts with managed care organizations that accept a set per-member, per-month payment, known as a capitation payment.

Federal Medicaid funding to the states and the District of Columbia is open-ended—that is, not subject to any cap. The federal government reimburses each state for a portion of the state's Medicaid expenditures. The federal share is known as the federal medical assistance percentage (FMAP). The FMAP is determined by a formula set in statute and varies by state, with a higher reimbursement rate provided to states with lower per capita incomes, and vice versa.<sup>18</sup> There is a statutory minimum FMAP rate of 50 percent and a statutory maximum FMAP rate of 83

---

<sup>17</sup> See Annie L. Mach et al, [Puerto Rico and Health Care Finance: Frequently Asked Questions](#), Congressional Research Service, June 27, 2016.

<sup>18</sup> As of Fiscal Year 1998, the District of Columbia's FMAP rate is set by statute at 70 percent. Without this exception, it would be at the statutory minimum of 50 percent.

percent.<sup>19</sup> In Fiscal Year 2016, nine states, including the District of Columbia, had an FMAP rate of 70 percent or above, with Mississippi having the highest at 74.17 percent.<sup>20</sup>

By contrast, in Puerto Rico and the other territories, federal Medicaid funding is subject to an annual cap pursuant to [Section 1108](#) of the Social Security Act (42 U.S.C. 1308). The cap increases annually according to the change in the Consumer Price Index for All Urban Consumers (CPI-U). Once the annual federal funding cap is reached, the territory government is responsible for the remaining cost of all Medicaid services. Puerto Rico’s annual cap in Fiscal Year 2016 was \$335.3 million.<sup>21</sup>

Also in contrast to the states, the FMAP rates for the territories are not based on per capita income, but rather are fixed in federal statute. Prior to July 1, 2011, the statutory FMAP rate for the territories was 50 percent. If the FMAP rates for the territories were calculated based on per capita income, each territory would have an FMAP rate in the 70 to 80 percent range.<sup>22</sup>

Members of the Task Force recognize that the ACA contained both positive and negative elements for the territories’ Medicaid programs, insofar as the law provided additional funding but made that funding temporary. Specifically, the ACA provided for a one-time increase in Medicaid funding for the territories of \$7.3 billion, of which Puerto Rico received \$6.4 billion. The ACA also permanently increased the territories’ statutory FMAP rate from 50 percent to 55 percent—still below the FMAP rate each territory would receive if its rate were based on per capita income.

---

<sup>19</sup> This discussion involves the “regular” FMAP rate. Current federal law provides for higher—“enhanced”—FMAP rates for certain services or population groups, which is not pertinent for present purposes.

<sup>20</sup> This information is drawn from Alison Mitchell, “Medicaid’s Federal Medical Assistance Percentage (FMAP),” Congressional Research Service, February 9, 2016.

<sup>21</sup> According to the Centers for Medicare and Medicaid Services, Puerto Rico’s annual cap was \$45 million in Fiscal Year 1983, \$79 million in Fiscal Year 1993, \$207.3 million in Fiscal Year 2003, and \$280 million in Fiscal Year 2010. The Fiscal Year 2016 cap was \$11.1 million for American Samoa, \$5.9 million for the Northern Mariana Islands, \$16.3 million for Guam, and \$16.8 million for the U.S. Virgin Islands.

<sup>22</sup> According to CRS, Puerto Rico’s FMAP rate would likely be 83 percent, the maximum rate allowable under current Medicaid law. See Annie L. Mach et al, [Puerto Rico and Health Care Finance: Frequently Asked Questions](#), Congressional Research Service, June 27, 2016, at page 25, footnote 88.

To date, according to CMS, Puerto Rico has drawn down all but approximately \$1 billion of this \$6.4 billion in supplemental funding.<sup>23</sup> Based on CMS’s projections, Puerto Rico’s supplemental funding will be depleted before the end of calendar year 2017, a date that has come to be known as the “Medicaid cliff.” Once Puerto Rico depletes this supplemental funding, it will revert to receiving only its annual capped federal Medicaid allotment, which is expected to be \$357.8 million in Fiscal Year 2018.<sup>24</sup>

Members of the Task Force understand the often-heard argument that Puerto Rico does not receive state-like treatment under Medicaid because the program is financed from the general fund of the United States, and individuals and businesses in Puerto Rico are not required under federal law to contribute to the general fund to the same degree and extent as their counterparts in the states. Some members of the Task Force believe that different treatment on the tax-contribution side of the ledger may warrant different treatment on the federal outlay side of the ledger. Other members of the Task Force do not subscribe to this view. However, all members of the Task Force believe that, even if differential tax treatment may potentially serve as an argument against *equal* treatment for Puerto Rico under Medicaid, more *equitable* treatment should still be considered.

While it would be wrong to attribute Puerto Rico’s annual deficits and accumulated debt solely, or even mainly, to the disproportionate burden it bears in financing its Medicaid program, it would also be wrong to deny that this funding disparity has been a meaningful factor contributing to Puerto Rico’s fiscal condition.

Inadequate federal financing for Puerto Rico’s Medicaid program long pre-dates the 2010 ACA. It will remain an urgent problem whether the ACA is retained or not.

Inadequate federal financing for Puerto Rico’s Medicaid program may “save” federal taxpayer dollars in the short term. However, over time, these savings are likely to be at least partially offset by the additional costs borne by the federal government and state governments as a result of conditions-based migration from Puerto Rico to the U.S. mainland. The costs will be

---

<sup>23</sup> Puerto Rico drew down an average of \$917 million in supplemental funding annually between Fiscal Year 2012 and Fiscal Year 2016. In Fiscal Year 2012, the first full year in which this funding was available, Puerto Rico drew down \$564 million. In Fiscal Year 2016, the most recent completed fiscal year, Puerto Rico drew down \$1.3 billion.

<sup>24</sup> In addition to its annual capped federal allotment under Section 1108 of the Social Security Act, Puerto Rico receives CHIP funding (\$180 million in Fiscal Year 2016); so-called enhanced allotment program (EAP) funding under Section 1935 of the Social Security Act (\$49 million in Fiscal Year 2016, less than half of which it was able to utilize, as detailed in the “Medicare Part D” section below); electronic health records (EHR) funding (\$35 million in Fiscal Year 2014); and administrative funding for its Medicaid Management Information System (MMIS; \$900,000 in Fiscal Year 2014).

particularly significant for states, like Florida, that are popular destinations for individuals from Puerto Rico.

If Congress does not enact legislation to avoid the impending Medicaid cliff, the consequences for the health care system in Puerto Rico are likely to be severe. The government of Puerto Rico, which currently lacks the ability to borrow money in the capital markets to fill the large hole that will be left by the loss of federal funding, would presumably be compelled either to drop hundreds of thousands of current enrollees from the Medicaid program (harming quality of life and spurring outmigration) or to reallocate funds from other areas, such as payments to creditors and the provision of public services.

The approaching Medicaid cliff, a foreseeable consequence of the funding structure established in the ACA's provisions regarding the territories, presents policymakers with the need to address this issue in the near term. Given its magnitude, the cliff is certain to disrupt any existing stability in the provision of health care services in Puerto Rico for a large number of beneficiaries.

The Task Force makes the following recommendations:

- The Task Force believes that Puerto Rico and the other territories should be treated in a more equitable and sustainable manner under the Medicaid program, in order to improve patient outcomes in the territories, to strengthen the health care systems in the territories, to enhance federal oversight of those systems, to reduce the incentive for migration from the territories to the states and the associated financial costs to state governments and the federal government, and to stabilize and strengthen the fiscal condition of the territory governments. To that end, the Task Force recommends that **Congress** enact fiscally-responsible legislation to address the impending Medicaid cliff established by the ACA. The Task Force recommends that Congress begin to address the funding issue early in calendar year 2017 to enable the Puerto Rico Medicaid agency to engage with more certainty when formulating capitation payment contracts with its managed care organizations for Puerto Rico Fiscal Year 2017-2018, which begins on July 1, 2017. In addition, the Task Force recommends that, going forward, federal financing of the Medicaid programs in Puerto Rico and the other territories should be more closely tied to the size and needs of the territory's low-income population. Finally, the Task Force recommends that any additional federal Medicaid funding provided to Puerto Rico must be paired with appropriate oversight of and safeguards on Puerto Rico's Medicaid program through use of the MFCU and MMIS mechanisms.
- Federal law requires every state, the District of Columbia, and each U.S. territory to operate a [Medicaid Fraud Control Unit](#) (MFCU) to investigate and prosecute Medicaid provider fraud and patient abuse or neglect under state law, unless the state or territory receives a waiver by

demonstrating to the satisfaction of the Secretary of HHS that the operation of a MFCU would not be cost-effective.<sup>25</sup> MFCUs are typically part of the state Attorney General’s office; employ teams of investigators, attorneys, and auditors; and must be separate and distinct from the state Medicaid agency. Currently, 49 states (North Dakota being the exception) and the District of Columbia have MFCUs. Federal law provides for an enhanced FMAP rate to support MFCUs. None of the five territories operate a MFCU, presumably inhibited from doing so because of the annual federal Medicaid funding cap that applies to the territories.<sup>26</sup> The Task Force recommends that **Congress** enact legislation to remove the current disincentive to establish MFCUs that exists in the territories as a consequence of the annual funding cap.<sup>27</sup> Once that occurs, the Task Force recommends that the government of Puerto Rico establish a MFCU.

- States and territories are required to operate an automated claims processing and information retrieval system, or [Medicaid Management Information System \(MMIS\)](#), to administer their state Medicaid plans. The overarching purpose of an MMIS is to enhance the efficiency and improve the internal controls over a jurisdiction’s Medicaid program and to minimize the potential for waste, fraud and abuse. Puerto Rico is already working with CMS to develop an MMIS, with \$55 million—\$46 million in federal funding and \$9 million in local funding—having been committed to this effort to date. In the written agreements between CMS and the government of Puerto Rico, there are several clearly-delineated targets and milestones to be achieved. The Task Force recommends that **Congress** ensure that Puerto Rico’s ongoing efforts to construct its MMIS continue to completion in compliance with the funding agreements with CMS, and believes that it is appropriate to require continued progress on the MMIS and achievement of targets and milestones set forth in the agreements with CMS as a condition for additional federal Medicaid funding.

---

<sup>25</sup> See Social Security Act 1902(a)(61), 1903(q).

<sup>26</sup> See [Testimony](#) of John Hagg, Director of Medicaid Audits, Office of Inspector General, U.S. Department of Health and Human Services, Hearing on “Strengthening Medicaid Program Integrity and Closing Loopholes,” House Committee on Energy and Commerce, September 11, 2015, at page 5 (noting that “[t]he major barrier to establishing a MFCU in Puerto Rico and the other territories is the nature of Medicaid funding for the territories,” since “the territories receive a capped appropriation to provide both Medicaid services and most administrative costs, which would include operation of a MFCU”).

<sup>27</sup> See H.R. 3444, Medicaid and CHIP Territory Fraud Prevention Act (114<sup>th</sup> Congress; Rep. Pitts), bipartisan legislation that would accomplish this objective.

## **B. Medicare**

### **I. Medicare Part A**

Medicare is a federal program that pays for covered health care services to individuals over age 65 and certain individuals with disabilities. Medicare Part A provides coverage for inpatient hospital services, as well as services like skilled nursing, home health, and hospice care. Unlike hospitals in the other territories, which are paid on a cost basis, subject to certain limitations, hospitals in Puerto Rico are paid using a prospective payment system that is comparable to the Medicare inpatient prospective payment system (IPPS) created to pay hospitals in the 50 states. Hospitals in Puerto Rico are not included in Medicare’s current definition of a “subsection (d) hospital”—which denotes hospitals located in the states. Congress enacted a separate prospective payment system for “subsection (d) Puerto Rico hospitals” in the Omnibus Budget Reconciliation Act of 1986, effective for payments starting in Fiscal Year 1986.

Eligible hospitals in the states and Puerto Rico that treat a certain share of low-income patients can receive additional payments—called Medicare Disproportionate Share Hospital (DSH) payments—to offset the financial effects of treating such patients. Prior to Fiscal Year 2014, DSH payments were provided by a single statutory formula that increased the inpatient prospective payment system (IPPS) reimbursement amount based on the disproportionate patient percentage (DPP). The DPP was based on a hospital’s share of low-income patients, defined as the share of Medicare inpatient days for individuals entitled to federal Supplemental Security Income (SSI) benefits out of a hospital’s total Medicare inpatient days (Medicare/SSI), plus the share of Medicaid inpatient days out of the hospital’s total inpatient days.

In Fiscal Year 2014 and subsequent years, DSH funding has been split into two payments with separate methodologies: (1) “empirically justified” DSH payments, which continue to be based on the traditional DPP, but are limited to 25 percent of the DSH payments that they would have received under prior law; and (2) “uncompensated care pool” fixed DSH payments, which are defined as 75 percent of aggregated operating DSH payments as calculated under the prior DSH formula, multiplied by 1 minus the annual percentage decline in the national uninsured rate. In Fiscal Year 2017, as a proxy for hospital uncompensated care data, the uncompensated care pool will be allocated to hospitals based on their share of Medicaid and Medicare SSI days relative to all other hospitals that receive DSH payments. CMS currently projects a 44 percent decline in the national uninsurance rate between 2013 and 2017, estimating that approximately \$6 billion will be allocated through the DSH uncompensated care pool in 2017.

Currently, Medicare/SSI is a factor in calculating each of the two different DSH payments. However, Congress has not extended the SSI program to Puerto Rico. Instead, Puerto Rico continues to use its own prior income-related disability payment program, called AABD. While

Puerto Rico hospitals may provide care to certain individuals living on the mainland who are eligible for SSI, the vast majority of Puerto Rico residents are ineligible for SSI. Therefore, using Medicare SSI days as a portion of total Medicare days to calculate the DSH uncompensated care pool payment formula—along with the failure to design a payment methodology that appropriately accounts for days provided to patients in both the Puerto Rico disability program and the SSI program—do place Puerto Rico hospitals at a disadvantage.

The Secretary of HHS, using administrative authority in the Fiscal Year 2017 Medicare IPPS final rule, modified the uncompensated care pool payment formula to use 14 percent of a Puerto Rico hospital's Medicaid days as a proxy for Medicare/SSI days. The Secretary did not use a proxy for Medicare/SSI in the empirically justified DSH payment formula, noting that the DPP is prescribed in statute for empirically justified DSH.

The Task Force makes the following recommendation:

- Because the SSI program does not apply in Puerto Rico, the Task Force recommends that **Congress** consider providing increased flexibility to the Secretary of HHS to identify data collection and analysis gaps that could be used to improve the accuracy and efficiency of Medicare DSH payments to Puerto Rico hospitals. For example, one possibility would be to develop a policy that uses a proxy that updates the empirically justified DSH payment formula calculation for subsection (d) Puerto Rico hospitals.

## II. Medicare Part B

Medicare Part B provides coverage for physicians' services, outpatient hospital services, durable medical equipment, outpatient dialysis, and other medical services. Residents of every state and territory *other than Puerto Rico* who are receiving Social Security benefits are automatically enrolled in both Part A and Part B, with coverage beginning the first day of the month they turn 65. In addition, disabled individuals who have received cash payments for 24 months under the Social Security disability programs are automatically enrolled in Part B unless they decline such coverage. Because beneficiaries must pay a premium for Part B coverage, they have the option of opting out of Part B coverage.

Those individuals who are not automatically enrolled in Medicare—for example, because they have not filed for Social Security benefits—must file an application for Part A and Part B with the Social Security Administration during their seven-month initial enrollment period, which begins three months before the month in which they turn 65. Beneficiaries who do not sign up for Part B during this initial enrollment period may have to pay a late-enrollment penalty for as long as they are enrolled in Part B. The late-enrollment penalty increases Part B monthly premiums by 10 percent for each full 12-month period that one could have had Part B but did not

sign up for it. Certain low-income beneficiaries may qualify for Part B premium assistance from Medicaid through a Medicare Savings Program (MSP). Beneficiaries in an MSP are not subject to late-enrollment penalties regardless of when they signed up for Medicare.

Under federal law, when residents of Puerto Rico turn 65 and start receiving Social Security benefits, they are automatically enrolled in Part A, but not automatically enrolled in Part B. Instead, beneficiaries in Puerto Rico are required to take the affirmative step of enrolling in Part B during their seven-month initial enrollment period. If they fail to enroll, they are subject to a lifetime late-enrollment penalty.<sup>28</sup>

The lack of an automatic Part B enrollment process in Puerto Rico has resulted in a disproportionate number of Medicare beneficiaries in Puerto Rico paying the lifetime late-enrollment penalty. Puerto Rico does not have an MSP program, so low-income beneficiaries subject to this penalty may be responsible for paying the full penalty amount in addition to their premiums. According to CMS, there are currently 5,739 Medicare beneficiaries in Puerto Rico who are paying a lifetime penalty for enrolling late in Part B. In addition, according to CMS, there are 108,678 individuals in Puerto Rico who are currently enrolled in Part A only, not Part B. Many of those individuals, if they do elect to enroll in Part B, will be subject to a lifetime late enrollment penalty.

The Task Force makes the following recommendations:

- The Task Force recommends that **Congress** amend federal law so that, going forward, Medicare beneficiaries in Puerto Rico are automatically enrolled in Medicare Part B with the option to opt out of coverage, the same way their counterparts in every state and other territory are treated.
- As long as Puerto Rico remains the only U.S. jurisdiction where Medicare beneficiaries are required to opt in to Part B coverage, the Task Force recommends that the **Centers for Medicare and Medicaid Services** and the **Social Security Administration** take timely and targeted steps to educate island residents about the existence of the opt-in requirement and the financial consequences of late enrollment.

### III. Medicare Part C

The Medicare Advantage program, or Medicare Part C, gives Medicare beneficiaries the option to receive covered benefits from private health plans that are paid a per-member, per-month amount to provide services covered by the traditional Medicare fee-for-service program for Part A and B benefits. Many Medicare Advantage plans provide additional supplemental benefits,

---

<sup>28</sup> See Social Security Act 1837(f)(3).

such as dental and vision. According to CRS, in May 2015, 75 percent of Medicare beneficiaries in Puerto Rico were enrolled in an MA plan, compared with 32 percent of beneficiaries in the 50 states and the District of Columbia. More than half of MA enrollees in Puerto Rico are in a special type of MA plan called a Special Needs Plan (SNP). While there are three different types of SNPs, nearly half of Puerto Rico beneficiaries are enrolled in a Dual-Eligible SNP (D-SNP), which is a plan that enrolls individuals who are eligible for both Medicare and Medicaid.<sup>29</sup> Dual eligible beneficiaries tend to [experience](#) high rates of chronic illness and multiple chronic conditions.

To address the needs of this particular population, the 2017 Medicare Advantage Final Call Letter included a number of policies to improve stability in the Medicare Advantage program in Puerto Rico. These policies include a change in payment that CMS estimates will result in increased revenue for MA plans in Puerto Rico. More specifically, the following policies have been adopted through the [2017 Medicare Advantage Final Call Letter](#):

- A change in the risk adjustment model that will increase payments to plans with high proportions of full benefit dual eligible beneficiaries, which CMS estimates will benefit Puerto Rico more than any other state or territory;
- An adjustment to the fee-for-service payment basis for plans in 2017 to reflect the higher payments made to hospitals in Puerto Rico in 2016;
- An adjustment to the weighting of the enrollment and risk scores for Medicare beneficiaries based on the nationwide proportion (rather than Puerto Rico alone) of Medicare beneficiaries enrolled in both Parts A and B in fee-for-service that have no Medicare claim reimbursements for a year. CMS applied a 4.4 percent adjustment to the pre-standardized Puerto Rico fee-for-service rates to help develop the benchmarks for 2017; and
- Changes to the Star Ratings System to reflect socioeconomic status specifically related to low income subsidy/dual eligible and/or disability status.<sup>30</sup>

The Task Force makes the following recommendation:

- The Task Force notes that the Medicare Advantage penetration rate continues to grow in the United States more generally as well as in Puerto Rico specifically, where the penetration

---

<sup>29</sup> See Annie L. Mach et al, [Puerto Rico and Health Care Finance: Frequently Asked Questions](#), Congressional Research Service, June 27, 2016, at page 15.

<sup>30</sup> See generally Centers for Medicare and Medicaid Services, [Supporting Medicare in Puerto Rico](#), April 4, 2016.

rate is higher than in any other U.S. jurisdiction. As more Medicare beneficiaries choose to enroll in the Medicare Advantage program, the Task Force recommends that **Congress and the Centers for Medicare and Medicaid Services** consider whether additional legislative or administrative steps may be warranted to ensure that MA plans, including those in Puerto Rico, are being fairly and properly compensated for the services they provide to beneficiaries.

#### IV. Medicare Part D

Medicare Part D provides an outpatient prescription drug benefit, either through private prescription drug plans that offer only drug coverage or through Medicare Advantage prescription drug plans that offer coverage as part of broader, managed-care plans. In the states and the District of Columbia, Medicare beneficiaries with incomes up to 150 percent of the federal poverty level are eligible to receive a low-income subsidy (LIS) from the federal government, which reduces or eliminates their monthly premium and other out-of-pocket costs associated with Part D.

Pursuant to federal law, residents of the territories are not eligible for the LIS.<sup>31</sup> In lieu of the LIS, federal law provides a fixed amount of funding to each territory to provide *Medicaid* coverage of prescription drugs for low-income Medicare beneficiaries. This funding is provided pursuant to Section 1935(e) of the Social Security Act, and is referred to as the enhanced allotment program (EAP). Currently, annual EAP funding to Puerto Rico is between \$40 million and \$50 million. This is substantially less than the aggregate amount of financial support that low-income Medicare beneficiaries in Puerto Rico would receive if residents of the territories were eligible for the LIS.

Each territory government is required to match its EAP funding at its regular Medicaid FMAP rate of 55 percent. This means for every dollar a territory spends on providing Medicaid coverage for prescription drugs to low-income Medicare beneficiaries, the territory draws down 55 cents from its allotted Section 1935(e) funding, up to the annual limit, and is responsible for the remaining 45 cents.

Because of the local match requirement, the territories (to varying degrees) have struggled to draw down EAP funding, often leaving much of the funding unused despite a significant need for the funding. For example, between Fiscal Year 2010 and Fiscal Year 2016, Puerto Rico has

---

<sup>31</sup> See Social Security Act 1860D-14(a)(3)(F).

been able to draw down only about 51 percent of its EAP funding, as reflected in the following chart.<sup>32</sup>

	EAP Allotment	PR Draw Down	Percentage
FY 2010	\$49,339,617	\$49,339,618	100.0%
FY 2011	\$51,701,315	\$23,716,209	45.87%
FY 2012	\$43,580,880	\$17,357,642	39.83%
FY 2013	\$44,156,704	\$21,818,368	49.41%
FY 2014	\$42,361,118	\$16,936,666	39.98%
FY 2015	\$44,040,604	\$9,240,022	20.98%
FY 2016	\$49,171,794	\$28,332,152	57.61%
<b>FY 2010 – FY 2016</b>	<b>\$324,352,032</b>	<b>\$166,740,677</b>	<b>51.41%</b>

The Task Force makes the following recommendations:

- The Task Force recommends that **Congress** eliminate the requirement that each territory government meet a local Medicaid matching requirement in order to draw down its annual EAP funding. The Task Force notes that the matching requirement has prevented the government of Puerto Rico and other territory governments from effectively utilizing EAP funding to help low-income Medicare beneficiaries purchase prescription drugs. The Task Force further recommends that Congress consider increasing the annual EAP allotment for each territory by a reasonable amount and in a fiscally responsible manner, so that the allotment is more closely tethered to actual need in each territory. Finally, the Task Force recommends that Congress explore the feasibility and cost of extending the LIS to residents of the territories and eliminating the EAP program.<sup>33</sup>

## V. CMS Administrative Flexibility

Because Puerto Rico and the other territories are treated differently than the states under federal health statutes, it is not uncommon for a literal interpretation by the Centers for Medicare and

<sup>32</sup> The data underlying this computation were provided by CMS. In addition, according to CMS data, the percentage of EAP funding utilized by the U.S. Virgin Islands between Fiscal Year 2010 and Fiscal Year 2016 was only 27 percent. The percentage utilized by American Samoa, Guam and the Northern Mariana Islands between Fiscal Year 2010 and Fiscal Year 2014 (more recent data have not been provided to the Task Force) was 94 percent, 81 percent, and 93 percent, respectively. However, there have been recent fiscal years in which both Guam and the Northern Mariana Islands drew down less than 55 percent of their EAP funding.

<sup>33</sup> See S. 2342, Territories Medicare Prescription Drug Assistance Equity Act of 2015 (114<sup>th</sup> Congress; Sen. Nelson); H.R. 4163, Territories Medicare Prescription Drug Assistance Equity Act of 2015 (114<sup>th</sup> Congress; Rep. Pierluisi); and Section 215 of S. 2675, Puerto Rico Recovery Act of 2016 (114<sup>th</sup> Congress; Sen. Menendez).

Medicaid Services of a statutory formula that provides for payments to physicians, hospitals or health plans to lead to anomalous results for Puerto Rico that may not have been intended by Congress, as evidenced by the Medicare Part A example discussed above.

The Task Force makes the following recommendation:

- The Task Force recommends that **Congress** consider providing the Centers for Medicare and Medicaid Services with flexibility to make reasoned and justifiable adjustments to a formula providing for payments to physicians, hospitals or health plans in Puerto Rico and the other territories. Use of this flexibility should be limited to any formula that is dependent in whole or in part on data that are not available or not reliable as it pertains to the territories, or dependent on factors that are inapplicable to the territories.

### **C. Family-to-Family Health Information Center Grant Program**

The Family-to-Family Health Information Center Grant program, called the F2F program, is administered by the Health Resources and Services Administration (HRSA) within HHS.<sup>34</sup>

The F2F program was established as part of the Family Opportunity Act, which was included in the Deficit Reduction Act of 2005 (P.L. 109-171). Pursuant to the program, HRSA makes competitive grants on an annual basis to support Family-to-Family Health Information Centers. These centers are primarily non-profit organizations operated by families with children and youth with special health care needs, and they provide education, training, peer support, and expertise in navigating health care systems for other families of children and youth with special health care needs. The law establishing the program makes grants available to support a single center in each of the 50 states and in the District of Columbia, but not in Puerto Rico or the other U.S. territories.<sup>35</sup> The F2F program is currently funded at \$5 million per year. Funding is distributed equally among centers in every state and the District of Columbia, with each center receiving about \$95,000 per year, regardless of the state's population.<sup>36</sup>

The Task Force makes the following recommendation:

---

<sup>34</sup> See Family Voices, Submission to Congressional Task Force on Economic Growth in Puerto Rico; Coralaidee Jimenez, Submission to Congressional Task Force on Economic Growth in Puerto Rico.

<sup>35</sup> See 42 U.S.C. 701(c)(5).

<sup>36</sup> In the 113<sup>th</sup> Congress, the Senate Finance Committee approved [S. 1871](#), the SGR Repeal and Medicare Beneficiary Access Act of 2013. Section 323 of S. 1871, which did not ultimately become law, would have made the territories eligible for the F2F program. See [Senate Report 113-135](#), at page 56.

- The Task Force recommends that **Congress** consider amending the law authorizing the Family-to-Family Health Information Center Grant program to enable Puerto Rico and the other territories to participate in the program, in a manner that does not dilute the funding currently available to the states and the District of Columbia.

#### **D. Maternal, Infant, and Early Childhood Home Visiting Program**

The Maternal, Infant, and Early Childhood Home Visiting Program, also known as the Federal Home Visiting Program, is administered by the Health Resources and Services Administration (HRSA) within HHS. The program supports home visiting services for families with young children who reside in communities that have concentrations of poor child health and other risk indicators. Home visits are conducted by nurses, mental health clinicians, social workers, or others with specialized training.

The law does not specify how funds are to be allocated to eligible entities in the states and territories. In practice, HRSA distributes Federal Home Visiting Program funds by both formula and competitive awards and, on its face, the funding formula treats states and territories the same. Between Fiscal Year 2010 and Fiscal Year 2015, funding was distributed according to the relative share of children under age five in families at or below 100 percent of the federal poverty line living in each state and territory. However, the poverty data are derived from the U.S. Census Bureau's Small Area Income Poverty Estimates (SAIPE), which are not available for the territories. There was a \$1 million funding minimum for state and territory grantees, and HRSA allocated this minimum level of funding to each of the territories from Fiscal Year 2011 through Fiscal Year 2015.

For Fiscal Year 2016, HRSA redesigned the funding allocation for formula grants. About one-third of funding is still allocated based on the share of children under age five in families at or below 100 percent of the federal poverty line in each state and territory, using 2013 SAIPE data that are not available for the territories. About two-thirds of funding is allocated based on the amount of competitive awards a state or territory received under the Federal Home Visiting Program between Fiscal Year 2013 and Fiscal Year 2015. There continues to be a \$1 million funding minimum for state and territory grantees, and each territory received the base allocation of \$1 million in Fiscal Year 2016.

The Task Force makes the following recommendation:

- The Task Force recommends that the **Health Resources and Services Administration**, when allocating funds to Puerto Rico under the Federal Home Visiting Program, utilize an appropriate alternative source for child poverty data, such as the Puerto Rico Community Survey, given that the data source currently used by HRSA to make allocations—the U.S.

Census Bureau's Small Area Income Poverty Estimates (SAIPE)—does not include the territories.

## 2. Federal Tax Policy

### A. Federal Tax Policy Toward Individuals and Families

The Task Force examined federal tax policy toward individuals and families residing in Puerto Rico and the other U.S. territories. The Task Force, which was directed by Section 409(g)(2) of PROMESA to recommend changes to federal law that could spur economic growth, reduce child poverty and attract investment to Puerto Rico, is making a specific recommendation related to the child tax credit. The Task Force is also making a broader recommendation on the subject of federal tax policy toward individuals and families in the territories to help guide federal policymakers going forward.

Under current law, the child tax credit (CTC) allows a family to reduce its federal tax liability—the taxes owed before tax credits are applied—by a maximum of \$1,000 per child. The CTC phases out for higher-income families.<sup>37</sup>

The CTC is refundable, meaning that if the value of the credit exceeds the amount of tax a family owes, the family may be eligible to receive a full or partial refund of the difference. The refundable portion of the credit is often called the additional child tax credit (ACTC). Families may receive the child tax credit as a reduction in tax liability (the non-refundable portion of the credit), a refundable credit (the ACTC), or a combination of both. For example, a family with two qualifying children and a tax liability of \$1,500 may receive the \$2,000 child tax credit (\$1,000 per child) as a \$1,500 reduction in their tax liability and a \$500 refund.

In the states and the District of Columbia, the amount of the ACTC is generally calculated using the earned income formula. Under this formula, a family may claim an ACTC equal to 15 percent of the family's earnings in excess of \$3,000, not to exceed the maximum credit amount (\$1,000 multiplied by the number of qualifying children). For example, a three-child family with annual earnings of \$20,000 would be eligible for an ACTC of \$2,550:  $[(\$20,000 - \$3,000) \times .15]$ .

Families with three or more children in the states and the District of Columbia may choose to calculate the ACTC using either the earned income formula or an alternative formula. The alternative formula is the family's federal payroll taxes (7.65 percent of earnings) minus the value of any earned income tax credit (EITC) the family received, not to exceed the maximum credit amount (\$1,000 multiplied by the number of qualifying children). In the relatively

---

<sup>37</sup> See Section 24 of the Internal Revenue Code.

infrequent event that the ACTC calculated under the alternative formula is larger than the ACTC calculated under the earned income formula, the larger credit can be claimed, but the credit can never exceed \$1,000 per qualifying child.

Under current law, families in Puerto Rico with one child or two children are generally not eligible for the ACTC. While families in Puerto Rico with three or more children are eligible for the ACTC, they must calculate their credit using the alternative formula, which caps the ACTC at the amount of annual federal payroll taxes the family pays. This is in contrast to their stateside counterparts, who can calculate their credit using either the earned income formula or the alternative payroll tax formula.

Families in Puerto Rico with three or more children claim the ACTC by filing [Form 1040-SS](#) directly with the Internal Revenue Service within the U.S. Department of the Treasury. The [Form](#) and accompanying [instructions](#) both make explicit that the ACTC can only be claimed by island families with three or more children.

The Task Force makes the following recommendations:

- The Task Force recommends that **Congress** amend Section 24 of the Internal Revenue Code to authorize otherwise eligible families in Puerto Rico with one child or two children to claim the additional child tax credit, with the amount of the credit equal to the amount of annual federal payroll taxes paid by the family or \$1,000 per qualifying child, whichever is lower.<sup>38</sup> This legislative change will provide the same treatment to families in Puerto Rico with one child or two children that is currently provided to island families with three or more children, reducing incentives for island families with less than three qualifying children to claim on Form 1040-SS that they have three or more qualifying children in order to receive the ACTC. It has been estimated that this proposal could benefit about 355,000 newly-eligible families and 404,000 newly-eligible children in Puerto Rico, with an average credit for all Puerto Rico families of \$770, which will help reduce child poverty on the island.
- Although the Task Force reached consensus on the child tax credit, the Task Force does not intend to foreclose debate on whether further modifications to federal tax policy toward individuals and families in Puerto Rico may be appropriate. To the contrary, the Task Force recommends that **Congress** carefully consider this topic. Potential options for examination include: (1) authorizing Puerto Rico families to claim the additional child tax credit using the earned income formula, not merely the alternative payroll tax formula; (2) extending the

---

<sup>38</sup> The Task Force recommends that Congress make a functionally equivalent legislative change for American Samoa, Guam, the Northern Mariana Islands, and the U.S. Virgin Islands.

earned income tax credit to eligible Puerto Rico households,<sup>39</sup> and (3) providing federal wage subsidies to employees and employers in Puerto Rico.<sup>40</sup>

Because the Task Force received numerous recommendations to extend the earned income tax credit (EITC) to Puerto Rico, the Task Force will address this topic briefly even though no consensus was reached. While there is some disagreement among Task Force members regarding the appropriateness of extending the EITC to workers in Puerto Rico, there is agreement that Puerto Rico's low labor force participation rate significantly contributes to the island's economic and fiscal problems. Studies have shown that the EITC increases labor force participation and reduces child poverty, but may have other effects on work incentives in phase-out ranges.

As noted elsewhere in the report, members of the Task Force understand that residents of Puerto Rico are not required to pay federal income taxes on their Puerto Rico-source income. However, like many of their fellow American citizens in the 50 states and the District of Columbia who receive the EITC and do not earn enough to incur a federal income tax liability, workers in Puerto Rico are subject to all federal payroll taxes. Notwithstanding the current absence of consensus, members of the Task Force agree that extension of the EITC to Puerto Rico both poses challenges and presents opportunities, and recommends that Congress explore ways to minimize the challenges and maximize the opportunities.

## **B. Other Federal Tax Provisions**

### **I. Cover Over of Rum Excise Tax Revenues to Puerto Rico and the U.S. Virgin Islands**

Federal excise taxes collected on rum produced in Puerto Rico and transported to the states are covered over—paid—to the treasury of Puerto Rico, and federal excise taxes collected on rum produced in the U.S. Virgin Islands and transported to the states are covered over to the treasury of the U.S. Virgin Islands. In addition, federal excise taxes collected on rum imported to the United States from foreign countries are covered over to Puerto Rico and the U.S. Virgin Islands pursuant to a formula established by the Alcohol and Tobacco Tax and Trade Bureau within the U.S. Department of the Treasury.<sup>41</sup> The primary purpose of the cover-over program is to help

---

<sup>39</sup> See S. 2203, Earned Income Tax Credit and Child Tax Credit Equity for Puerto Rico Act of 2015 (114<sup>th</sup> Congress; Sen. Menendez); and H.R. 3553, Earned Income Tax Credit Equity for Puerto Act of 2015 (114<sup>th</sup> Congress; Rep. Pierluisi).

<sup>40</sup> See S. 3503, Economic Mobility for Productive Livelihoods and Expanding Opportunity (EMPLEO) Act (114<sup>th</sup> Congress; Sen. Rubio).

<sup>41</sup> See Section 7652 of the Internal Revenue Code.

the two territories provide essential public services. The use of funding for public purposes is particularly critical now that the government of Puerto Rico is struggling to fund its health, education and public safety systems.

Federal excise taxes are imposed on rum at the generally applicable distilled spirits rate of \$13.50 per proof gallon.<sup>42</sup> Under current law, excise tax collections on imported rum, including rum produced in Puerto Rico and the U.S. Virgin Islands, are covered over to Puerto Rico and the U.S. Virgin Islands at the rate of \$13.25 per proof gallon. Of this amount, \$10.50 per proof gallon is in permanent law and the remaining \$2.75 per proof gallon requires periodic reauthorization by Congress as part of tax extenders legislation. The additional \$2.75 per proof gallon was most recently extended through December 31, 2016 as part of the Consolidated Appropriations Act, 2016 (P.L. 114-113).

The Task Force makes the following recommendations:

- The Task Force recommends that **Congress** make the full amount of the rum cover-over payment to Puerto Rico and the U.S. Virgin Islands permanent, rather than permanent in part and subject to tax extenders legislation in part. The Task Force further recommends that Congress increase the cover-over payment from the current rate of \$13.25 per proof gallon to the generally applicable distilled spirits rate, currently \$13.50 per proof gallon. At a minimum, the Task Force recommends that Congress extend the additional \$2.75 per proof gallon component of the rum cover-over payment beyond 2016. Failure to extend the provision will cause harm to Puerto Rico's (and the U.S. Virgin Islands') fiscal condition at a time when it is already in peril.

## II. Domestic Production Activities in Puerto Rico

The domestic production activities deduction, also known as the domestic manufacturing deduction, was established as part of the American Jobs Creation Act of 2004 (P.L. 108-357).<sup>43</sup> Under current law, Section 199 allows a company to receive a deduction equal to 9 percent of the taxable income that the company derives from "qualified production activities" within the United States. This effectively reduces the top federal tax rate that a company will pay on such income from 35 percent to 32 percent. "Qualified production activities" include, among other things: manufacturing; electricity, natural gas and water production; film production; and construction. Overall, about one-third of corporate activity nationwide qualifies for the deduction.

---

<sup>42</sup> See Section 5001 of the Internal Revenue Code.

<sup>43</sup> See Section 199 of the Internal Revenue Code; see also [Federal Tax Law And Issues Related To The Commonwealth Of Puerto Rico](#), Joint Committee on Taxation, September 28, 2015 (JCX-132-15).

Although the American Jobs Creation Act of 2004 did not authorize a company to receive the Section 199 deduction on income derived from qualified production activities within Puerto Rico, the Tax Relief and Healthcare Act of 2006 (P.L. 109-432) expanded Section 199 to include activities in Puerto Rico. However, the provision extending the Section 199 deduction to Puerto Rico applies on a temporary basis and therefore requires periodic reauthorization by Congress through tax extenders legislation. The provision has been extended five times since 2006, most recently in the Consolidated Appropriations Act, 2016 (P.L. 114-113), and is scheduled to expire on December 31, 2016. The Section 199 deduction is only available to U.S. companies that operate in Puerto Rico in branch form, which—in contrast to U.S. companies that operate in Puerto Rico in subsidiary form—are subject to full U.S. tax on the income from those operations on an immediate basis.

The Task Force makes the following recommendation:

- As long as the Section 199 domestic production activities deduction remains part of U.S. tax law, the Task Force believes that it should apply in Puerto Rico, a U.S. jurisdiction home to American workers. The Task Force recommends that **Congress** amend Section 199 so that it applies to Puerto Rico on a permanent basis. At a minimum, the Task Force recommends that Congress—for the sixth time since 2006—extend the provision beyond 2016. Failure to extend the provision will create a disincentive for existing and new U.S. businesses to conduct manufacturing operations in Puerto Rico, an outcome that Congress should seek to avoid.

### **III. Special Expensing Rules for Film and Television Productions**

Section 181 of the Internal Revenue Code allows a U.S. taxpayer to immediately deduct the cost of a qualified film, television, or live theatrical production, up to \$15 million (or \$20 million in the case of a production in certain low-income or economically distressed areas). This provision was most recently extended in the Consolidated Appropriations Act, 2016 (P.L. 114-113), and is scheduled to expire on December 31, 2016. To be a “qualified production,” 75 percent of the total compensation of the production must be “qualified compensation.”<sup>44</sup> The term “qualified compensation” is defined as “compensation for services performed in the United States by actors, directors, producers, and other relevant production personnel.”<sup>45</sup> The term “United States” means the 50 states and the District of Columbia, not Puerto Rico or the other U.S. territories.<sup>46</sup>

---

<sup>44</sup> See Section 181(d)(1).

<sup>45</sup> See Section 181(d)(3).

<sup>46</sup> See [Treasury Regulation Section 1.181-3\(d\)](#), September 30, 2011.

The Task Force makes the following recommendation:

- As long as Section 181 remains part of U.S. tax law, the Task Force recommends that **Congress** amend Section 181 to include Puerto Rico and the other territories within the definition of “United States.” The Task Force believes that Puerto Rico should have the same opportunity as the 50 states and the District of Columbia to generate economic activity and employment opportunities through film, television, and theatrical production, and notes that the ability to showcase local culture and scenery before global film and television audiences can significantly stimulate tourism.

### C. Federal Tax Policy Toward Businesses

As long as Puerto Rico remains a U.S. territory, and not a state or a sovereign nation, there will be a vigorous debate regarding how businesses with activities in Puerto Rico should be taxed by the federal government.

This debate has historical, philosophical and public policy dimensions. The debate is historical because there continues to be a dispute over the impact of a now-repealed provision in the Internal Revenue Code, the Section 936 “Puerto Rico and Possession Tax Credit,” which was enacted in 1976 and fully phased out by 2006.

Section 936 provided tax preferences for territory activities, enabling U.S. corporations to pay preferred rates on income generated by their Puerto Rico affiliates, thereby creating a “substantial incentive for U.S. investment in [Puerto Rico].”<sup>47</sup> Some assert that enactment of Section 936 was critical in promoting economic development in Puerto Rico and that its repeal was detrimental to economic growth and investment on the island.<sup>48</sup> Others argue that the economic benefits for Puerto Rico of Section 936 were overstated and inefficient. Critics of 936 point to a GAO study which found that tax benefits to corporations often exceeded wages paid, sometimes by a ratio of more than two to one.<sup>49</sup> The GAO report noted that, while Section 936

---

<sup>47</sup> See Sean Lowry, [Tax Policy and U.S. Territories: Overview and Issues for Congress](#), Congressional Research Service, October 7, 2016, at page 15; see also [Federal Tax Law And Issues Related To The Commonwealth Of Puerto Rico](#), Joint Committee on Taxation, September 28, 2015 (JCX-132-15).

<sup>48</sup> See, e.g., Hon. Alejandro García Padilla, Submission to Congressional Task Force on Economic Growth in Puerto Rico; and Puerto Rico Private Sector Coalition, Submission #1 to Congressional Task Force on Economic Growth in Puerto Rico.

<sup>49</sup> See [Puerto Rico and the Section 936 Tax Credit](#), Government Accounting [subsequently, Accountability] Office, June 8, 1993 (GAO-93-109), at pages 4, 5, 9 (observing that “[s]ignificant debate continues over the effectiveness of section 936 as an impetus for development in Puerto Rico,” and noting “[c]oncerns about the tax benefits in relation to employment” on the island).

provided substantial incentive for U.S. investment in Puerto Rico, “an increasing portion of total income produced in Puerto Rico [went] to U.S. and foreign investors [rather] than to Puerto Rican residents.”<sup>50</sup> In light of these and other data, some economists have argued that the decline of manufacturing jobs in Puerto Rico coincided with the repeal of Section 936, but was primarily attributable to other factors, including automation and other technological advancements at manufacturing facilities, increased import competition from other countries, and the reduction in manufacturing employment nationwide.<sup>51</sup>

Naturally, the debate over previous and current federal business tax policies toward Puerto Rico affects the debate over what federal tax policy toward Puerto Rico should be pursued by the next Congress. Speaking generally, those with more positive views toward Section 936 tend to look more favorably upon the prospect of a new tax incentive targeted at Puerto Rico, while those with more neutral or negative views toward Section 936 tend to look more skeptically upon the prospect of a new tax incentive aimed at the island. Those in the latter category do not necessarily oppose a new federal tax policy to encourage investment in Puerto Rico, but prefer that it be a policy of general applicability designed to encourage investment in economically-distressed areas throughout the country, including but not limited to Puerto Rico.<sup>52</sup>

The Task Force makes the following recommendations:

- The Task Force believes that Puerto Rico is too often relegated to an afterthought in congressional deliberations over federal business tax reform legislation. The Task Force recommends that **Congress** make Puerto Rico integral to any future deliberations over tax reform legislation.
- The Task Force recommends that **Congress** continue to be mindful of the fact that Puerto Rico and the other territories are U.S. jurisdictions, home to U.S. citizens or nationals, and that jobs in Puerto Rico and the other territories are American jobs.

---

<sup>50</sup> See [Puerto Rico and the Section 936 Tax Credit](#), Government Accounting [subsequently, Accountability] Office, June 8, 1993 (GAO-93-109), at page 12.

<sup>51</sup> See, e.g., Arthur MacEwan and J. Tomas Hexner, Submission #6 to Congressional Task Force on Economic Growth in Puerto Rico.

<sup>52</sup> See, e.g., Arthur MacEwan and J. Tomas Hexner, Submission #2 to Congressional Task Force on Economic Growth in Puerto Rico (urging Congress to enact legislation establishing “Investment Zones” in order to “supply a strong incentive for firms to establish new operations and expand existing operations in those economically depressed areas of the country”; noting that this legislation “would apply to the whole country as a national policy, [but] the benefits to Puerto Rico would be especially large”).

- The Task Force is open to the prospect of **Congress** providing U.S. companies that invest in Puerto Rico with more competitive tax treatment as long as appropriate guardrails are designed to ensure the company is creating real economic activity and employment on the island.

### 3. Energy

On September 30<sup>th</sup>, the Task Force held a staff-level briefing with officials from the U.S. Department of Energy (USDOE) to discuss Puerto Rico’s electricity generation and distribution system. There is a consensus that the high cost and low reliability of electric power in Puerto Rico is one of the most serious challenges confronting households and businesses, and a significant obstacle to economic growth on the island.<sup>53</sup>

Puerto Rico has no conventional energy resources, and relies heavily on shipments of imported fuel to generate electricity. According to the U.S. Energy Information Administration (EIA) [profile](#) on Puerto Rico, in 2015 Puerto Rico generated 51 percent of its electricity from petroleum, 31 percent from natural gas, 16 percent from coal, and 2 percent from renewable sources (predominantly wind, solar and hydropower). The numbers provided by the Puerto Rico Electric Power Authority (PREPA) are different than the EIA numbers, and appear to indicate that Puerto Rico currently generates close to 62 percent of its electricity from petroleum and less than 19 percent from natural gas. To place this in context, according to the [EIA](#), in 2015 the 50 states and the District of Columbia generated 33 percent of their electricity from natural gas, another 33 percent from coal, 20 percent from nuclear, 13 percent from renewable sources, and only 1 percent from petroleum.<sup>54</sup> Few, if any, observers question the conventional wisdom that Puerto Rico should take steps to reduce its disproportionate reliance on petroleum and increase its use of natural gas—of which the United States is now the world’s largest producer—and renewable energy sources like solar power if economically viable.<sup>55</sup>

The price of electricity in Puerto Rico is high, while the ability of some residents of Puerto Rico—where the median annual income is \$18,626—to pay is low. According to the EIA, the average price of electricity sold to the residential sector in Puerto Rico between 2005 and 2015

---

<sup>53</sup> See, e.g., William C. Dudley, President and Chief Executive Officer, Federal Reserve Bank of New York, “[Opportunities for Economic Growth in Puerto Rico](#),” November 29, 2016.

<sup>54</sup> According to the EIA, American Samoa, Guam, the Northern Mariana Islands, and the U.S. Virgin Islands generate all or nearly all of their electricity from imported petroleum.

<sup>55</sup> See, e.g., the EIA [profile](#) of Hawaii (“In 2015, Hawaii generated more solar electricity per capita from distributed facilities than any other state, and solar energy from both utility-scale and distributed resources generated 35% of Hawaii’s renewable electricity.”).

was 20.5 cents per kilowatt hour, peaking at 30.6 cents per kilowatt hour in February 2013.<sup>56</sup> Currently, the price of electricity for residential customers in Puerto Rico is higher than the price of electricity in any of the 48 contiguous states, roughly the same as the price in Alaska, and lower than the price in Hawaii (27.45 cents per kilowatt hour in August 2016).<sup>57</sup>

The price of electricity in Puerto Rico is also volatile, rising or falling based on the shifting price of crude oil in the world market, whereas the price of electricity in the United States is relatively stable.<sup>58</sup> In addition to its high and variable cost, electricity in Puerto Rico is subject to periodic supply disruptions.<sup>59</sup>

Puerto Rico's energy system is dominated by the Puerto Rico Electric Power Authority (PREPA), a public corporation in deep financial distress. PREPA owns and operates all but two of the power plants in Puerto Rico and controls the island's transmission grid. PREPA has often operated inefficiently and been governed in an opaque manner. Long overdue efforts are underway to reform operations at PREPA and, while progress has been made, it is clear that additional progress is required.<sup>60</sup>

Puerto Rico did not have an electricity regulatory body to oversee PREPA or regulate electricity rates until May 2014, when a law was enacted establishing the [Puerto Rico Energy Commission](#)

---

<sup>56</sup> In this same time period, the average price of electricity sold to the residential sector in the 50 states and the District of Columbia was 11.4 cents per kilowatt hour.

<sup>57</sup> See EIA, Rankings: Average Retail Price of Electricity to Residential Sector, August 2016.

<sup>58</sup> See [Report by the President's Task Force on Puerto Rico's Status](#), March 2011, at page 71 (“When the price of oil spikes, as it did in the summer of 2008, the effect on businesses and other consumers is devastating. Those high and unpredictable energy costs have made the Island less desirable for businesses, which, in turn, has contributed to a declining manufacturing base and increased unemployment. Moreover, Puerto Ricans have less disposable income because their utility bills are among the highest in the nation.”).

<sup>59</sup> For example, in late September 2016, a fire at a Puerto Rico Electric Power Authority (PREPA) power plant in southern Puerto Rico left virtually all of its customer base of 1.5 million households without power—some for several days—and caused major disruptions to the island's economy.

<sup>60</sup> See [Testimony](#) of Lisa Donahue, Hearing on “Exploring Energy Challenges and Opportunities Facing Puerto Rico, House Committee on Natural Resources, Subcommittee on Energy and Mineral Resources, January 12, 2016.

(PREC).<sup>61</sup> The law required PREPA to prepare its first-ever [Integrated Resource Plan](#) (IRP), on terms established by PREC and subject to PREC’s approval.<sup>62</sup>

The Task Force makes the following recommendations:

- The Task Force believes that the Puerto Rico Electric Power Authority’s record of service has not inspired confidence among its customer base in Puerto Rico, and recommends that the **government of Puerto Rico** continue efforts to make operational reforms at PREPA, improve the efficiency of electricity generation and transmission, and diversify Puerto Rico’s energy supply—all with the ultimate goal of making electric power more reliable and affordable.
- The Task Force recommends that **PREPA** and the **Puerto Rico Energy Commission** seek technical assistance from the U.S. Department of Energy, and recommends that the **U.S. Department of Energy** (USDOE) provide all authorized forms of technical and financial assistance. The Task Force has been advised that PREPA and other government of Puerto Rico agencies have shown reluctance in the past to request technical assistance from USDOE, including during the September 2016 blackout, and the Task Force recommends that any such reluctance be set aside.
- In December 2014, Congress enacted the [Fiscal Year Consolidated and Further Continuing Appropriations Act, 2015](#) (P.L. 113-235). Section 9 of the law requires the Secretary of the Interior to appoint a team of technical, policy and financial experts to develop an “energy action plan” for each of the territories, including Puerto Rico. In Section 505(d) of PROMESA, Congress reassigned responsibility for crafting the plan for Puerto Rico from the U.S. Department of the Interior to the U.S. Department of Energy. The Task Force recommends that the **U.S. Secretary of Energy** appoint a team of experts as soon as practicable, but not later than the statutory deadline of March 27, 2017; that the team of experts prepare the energy action plan in a timely manner; that the U.S. Secretary of Energy publish the energy action plan on the U.S. Department of Energy’s website; and that the U.S. Secretary of Energy annually update Congress on the efforts that Puerto Rico has made to implement the energy action plan, as required by statute.

---

<sup>61</sup> See [Puerto Rico Law 57-2014](#), the “Puerto Rico Energy Transformation and RELIEF Act.”

<sup>62</sup> On September 23, 2016, PREC issued its “[Final Resolution and Order](#),” disapproving the IRP submitted by PREPA, approving a modified IRP, ordering PREPA to modify the IRP in line with PREC’s requirements, and ordering PREPA “to ensure that its future IRPs comply with its legal obligations and satisfy professional standards.” For the complete PREC docket on this matter, see [here](#) (CEPR-AP-2015-0002).

- The Task Force recommends that the **U.S. Department of Energy** assess whether Puerto Rico receives equitable treatment relative to other jurisdictions under grant programs for energy-related research and, if it does not, recommends that USDOE resolve any inequities.

#### 4. Federal Statistical Programs

A federal statistical agency is an agency or unit of the executive branch whose primary activities are the collection and publication of information for statistical purposes. The principal federal statistical agencies include the:

- [U.S. Census Bureau](#), within the U.S. Department of Commerce;
- [Bureau of Economic Analysis \(BEA\)](#), within the U.S. Department of Commerce;
- [Bureau of Labor Statistics \(BLS\)](#), within the U.S. Department of Labor;
- [National Agricultural Statistical Service \(NASS\)](#), within the U.S. Department of Agriculture;
- [Economic Research Service \(ERS\)](#), within the U.S. Department of Agriculture
- [National Center for Education Statistics \(NCES\)](#), within the U.S. Department of Education;
- [Bureau of Justice Statistics \(BJS\)](#), within the U.S. Department of Justice;
- [National Center for Health Statistics \(NCHS\)](#), within the Centers for Disease Control and Prevention, within the U.S. Department of Health and Human Services;
- [Bureau of Transportation Statistics \(BTS\)](#), within the U.S. Department of Transportation;
- [National Center for Science and Engineering Statistics \(NCSES\)](#), within the National Science Foundation; and
- [U.S. Energy Information Administration \(EIA\)](#), within the U.S. Department of Energy.

Responsibility for coordinating the [federal statistical system](#) rests with the Office of Statistical and Science Policy (SSP), within the Office of Information and Regulatory Affairs, within the [Office of Management and Budget](#). SSP is led by the U.S. Chief Statistician.

The U.S. Chief Statistician seeks to ensure the effectiveness of the federal statistical system by, among other things, (1) establishing statistical policies and identifying priorities for improving statistical programs; (2) promoting integration across the federal statistical system by serving as chair of the Interagency Council on Statistical Policy, consisting of the principal statistical agencies; (3) annually preparing the “Statistical Programs of the United States Government” document, most recently released in September 2015 for [Fiscal Year 2016](#); and (4) preparing the “[Strengthening Federal Statistics](#)” chapter of the “Analytical Perspectives” volume of the President’s annual budget request to Congress.

As the “Strengthening Federal Statistics” chapter notes:

The ability of governments, businesses, and the general public to make informed choices about budgets, employment, investments, taxes, and a host of other important matters depends critically on the ready and equitable availability of relevant, accurate, timely, and objective Federal statistics. Taken together, the data produced by the decentralized Federal statistical system form a robust evidence base to support both public and private decision-making.

This view was echoed by William C. Dudley, the president and chief executive officer of the Federal Reserve Bank of New York, in a 2010 [speech](#) delivered in Puerto Rico:

The private and public sectors both need accurate, timely and comprehensive economic statistics to perform effectively. It is impossible to make good decisions without a solid factual basis for those decisions. For example, the government needs good economic information to develop effective fiscal, economic development and regulatory policy. Likewise, to make the best production, investment and pricing decisions, businesses need accurate and timely information on things such as wages, income and prices. Poor quality information increases uncertainty and this uncertainty inhibits well-considered risk-taking and investment decisions.

In its September 15<sup>th</sup> [status update](#), the Task Force wrote as follows:

Like other observers, the Task Force is concerned about the relative lack of reliable data pertaining to certain aspects of the economic, financial, and fiscal situation in Puerto Rico, which are necessary for productive analyses that may lead to sound public policy recommendations. Therefore, the Task Force intends to analyze the extent to which Federal statistical products that measure economic and financial activity in the states might also provide equivalent information for Puerto Rico and other territories, and the Task Force intends to explore ways in which any such data gaps can be responsibly closed.

On October 21<sup>st</sup>, the Task Force held a staff-level briefing with officials from three of the principal federal statistical agencies—the U.S. Census Bureau, the Bureau of Labor Statistics, and the National Agricultural Statistical Service. On October 26<sup>th</sup>, the Task Force held a staff-level briefing with officials from the Bureau of Economic Analysis (along with officials from other divisions within the U.S. Department of Commerce). The Task Force also communicated with the Bureau of Justice Statistics, which on September 14<sup>th</sup> sent a letter to a member of the Task Force regarding Puerto Rico’s treatment under BJS statistical programs. The Task Force received multiple written submissions that discuss this topic, including a letter from the executive director of the Puerto Rico Institute of Statistics.

Based on the information it obtained, the Task Force has confirmed that Puerto Rico—and, to an even greater extent, the four smaller U.S. territories, where sample sizes can pose a problem—are currently excluded from a considerable number of the statistical programs conducted by the principal federal statistical agencies, including some of the most important programs.

To help illustrate the point, **Appendix 3** contains a table prepared by the Task Force with the assistance of the U.S. Census Bureau that lists the main statistical programs (censuses and surveys) conducted by the Census Bureau, either on its own or in conjunction with another federal agency. The table describes whether the program collects and publishes state-by-state information and, if so, whether Puerto Rico information is included as well. If the program provides only national or regional level data, the table describes whether Puerto Rico is included in the national or regional totals.

The Task Force recognizes that a federal statistical agency may need to take a number of steps before it can include Puerto Rico in a particular statistical program from which it is presently excluded—including conducting a feasibility study, expending or reprogramming current agency funding or requesting additional funding from Congress, and obtaining cooperation and collaboration from local partners, such as the Puerto Rico Institute of Statistics and the Puerto Rico Planning Board. The Task Force understands that there may be certain impediments to action and that the effort may need to proceed in incremental fashion. However, the Task Force believes this to be a worthwhile endeavor that will benefit federal and local policymakers, current and potential investors, and the Puerto Rico public.

The Task Force makes the following recommendations:

- The Task Force recommends that the **U.S. Chief Statistician** place the subject of Puerto Rico’s inclusion in federal statistical programs on the agenda of the Interagency Council on Statistical Policy, develop an action plan consisting of short-term, medium-term, and long-term objectives, and describe this action plan in the “Statistical Programs of the United States Government” document submitted annually to Congress.
- The Task Force recommends that the **Census Bureau** take all reasonable steps to include Puerto Rico in its federal statistical programs, including the quinquennial Census of Governments (and its associated annual and quarterly surveys and summaries regarding public employment and payroll, public pensions, state government tax collections, and state and local government finances);<sup>63</sup> the Survey of Business Owners and Self-Employed

---

<sup>63</sup> See, e.g., Federal Reserve Bank of New York, [An Update on the Competitiveness of Puerto Rico’s Economy](#), July 31, 2014, at page 11 (noting that “the Census of Governments does not survey Puerto

Persons (SBO); the Building Permits Survey (BPS), which is currently published monthly for the states but only annually for Puerto Rico; and the Quarterly Workforce Indicators (QWI).<sup>64</sup>

- Puerto Rico is excluded from Census Bureau statistical programs that provide information on housing, such as the American Housing Survey (AHS), the Construction Progress Reporting Survey (CPRS), the Housing Vacancy Survey (HVS), the Manufactured Housing Survey (MHS; conducted jointly with the U.S. Department of Housing and Urban Development), and the Value of Construction Put in Place Survey (VIP). The Task Force recommends that the **Census Bureau**, in coordination with the government of Puerto Rico, examine the feasibility of including Puerto Rico in some or all of these products, or identify alternative means of collecting and publishing reliable data on the housing market in Puerto Rico.
- The Task Force recommends that the **Census Bureau** ensure that the quinquennial Economic Census of Island Areas (IA), which does include Puerto Rico, is producing data that is roughly equivalent in terms of both substance and timing to the data produced by the quinquennial Economic Census, which does not include Puerto Rico. The Task Force further recommends that the Census Bureau assess whether it would be preferable to include Puerto Rico in the national Economic Census rather than the Census of Islands Areas.
- The Task Force recommends that the **Bureau of Labor Statistics** and the **Census Bureau** take all reasonable steps to include Puerto Rico and the other territories in the Current Population Survey (CPS), the primary source of labor statistics in the United States. The Task Force notes that Section 404 of PROMESA expresses the “Sense of Congress” that a study should be conducted to “determine the feasibility of expanding data collection to include Puerto Rico and the other United States territories” in the CPS and that, if necessary, the Census Bureau “should request the funding required to conduct this feasibility study as part of its budget submission to Congress for fiscal year 2018.” The Task Force notes that BLS and the Census Bureau worked with the Task Force to begin to determine the feasibility and costs of such expansion.
- Puerto Rico’s K-12 public education system falls short in numerous, troubling respects.<sup>65</sup> As described in the table in Appendix 2, funding for Puerto Rico is capped under various federal

---

Rico as part of its annual program to collect information on the fiscal policies of the states and their constituent localities”).

<sup>64</sup> The Task Force notes that the Census Bureau recently added Puerto Rico to its web-based application, [My Congressional District](#), which was established in [2003](#) as a way to provide policymakers and the public with easy access to Census Bureau statistics about each congressional district.

education programs; nevertheless, according to CRS, Puerto Rico still receives more federal education funding per public elementary and secondary school student than any state or the District of Columbia (\$2,841 in school year 2012-2013). Given the importance of education, the Task Force recommends that the **National Center for Education Statistics** (NCES) collect and publish data for Puerto Rico in the same manner that it collects and publishes data for the states, to the greatest extent possible.<sup>66</sup>

- Although the agricultural sector in Puerto Rico is relatively small, with about 17,000 of the one million employed individuals on the island working directly in “farming, forestry and fishing,” the sector has grown in recent years according to local government statistics, and has the potential to expand further and create jobs.<sup>67</sup> The National Agricultural Statistical Service includes Puerto Rico in the Census of Agriculture, which was last produced in [2012](#) and will next be produced in 2017. The Task Force recommends that the **National Agricultural Statistical Service** include Puerto Rico in its relevant commodity surveys or that it identify an alternative method of producing reports on the island’s agricultural sector on at least an annual basis. The Task Force further recommends that NASS explore the feasibility of reestablishing a physical presence in Puerto Rico.
- As discussed elsewhere in this report, Puerto Rico has a higher homicide rate than any state, and the relative lack of public safety on the island undermines economic growth and quality of life. Puerto Rico is excluded from most statistical programs sponsored by the Bureau of Justice Statistics, including programs that provide information on crime victims, identity theft, prisoners and prisons, probationers, parolees, criminal justice expenditures, and contacts between the police and the public. The Task Force recommends that the **Bureau of Justice Statistics** take all reasonable steps to include Puerto Rico in its statistical programs.
- The National Survey on Drug Use and Health (NSDUH) is an annual survey funded by the Substance Abuse and Mental Health Services Administration (SAMHSA) within HHS, and it provides both state-level and national-level data on drug and substance abuse, among other

---

<sup>65</sup> See, e.g., Federal Reserve Bank of New York, [Human Capital and Education in Puerto Rico](#), Liberty Street Economics, August 11, 2016; National Center for Education Evaluation and Regional Assistance, [A Comparison of Two Methods of Identifying Beating-the-Odds High Schools in Puerto Rico](#), December 2016.

<sup>66</sup> To cite one instance where this does not occur, NCES provides a [State Education Data Profile](#) on its website for each state and the District of Columbia, but not for Puerto Rico or the other territories. Although NCES does provide information on Puerto Rico elsewhere on its website, for example [here](#) and [here](#), the data furnished are not as extensive or user-friendly.

<sup>67</sup> See [Statistical Appendix](#), Puerto Rico Planning Board’s Fiscal Year 2015 Economic Report to the Governor and Legislative Assembly, at pages A-26, A-27, A-65; see also Danica Coto, [Puerto Rico Finds Unexpected Source of Growth in Agriculture](#), Associated Press, September 28, 2016.

topics. NSDUH data are used by multiple federal agencies, including by the National Guard Bureau to make annual allocations to state and territory national guards under the National Guard Counterdrug Program. Puerto Rico and the other territories are excluded from the NSDUH. The Task Force recommends that the **Substance Abuse and Mental Health Services Administration**, and the non-profit company it has selected to administer the NSDUH through Fiscal Year 2017, provide an update to the appropriate congressional committees on the status of its effort to include Puerto Rico and the other territories in this survey.

- Puerto Rico is excluded from a number of statistical programs conducted by the National Center for Health Statistics, such as the [National Health Interview Survey](#), which is the principal source of information on the health of the U.S. population. The Task Force recommends that the **National Center for Health Statistics** take reasonable steps to include Puerto Rico and the other territories in its programs, particularly when state-level data are produced.
- As discussed elsewhere in this report, the high cost and unreliability of electric power in Puerto Rico is a challenge facing island households and businesses, hampering economic growth. The Task Force notes that, while the U.S. Energy Information Administration website does provide information for Puerto Rico and the other territories in its “[State Profiles](#)” section, the information furnished for Puerto Rico is not as detailed or as up-to-date as the information furnished for the states. The Task Force recommends that the **U.S. Energy Information Administration** work to close the remaining data gaps.
- In its numerous meetings with federal agencies, the Task Force heard that the Puerto Rico Institute of Statistics, which was established under Puerto Rico law in 2003 but did not begin operating until 2007, has emerged as a highly professional, autonomous, and apolitical organization that is bringing greater transparency to economic, financial and fiscal conditions on the island. Recognizing that the government of Puerto Rico faces a difficult fiscal environment, the Task Force recommends that the **government of Puerto Rico** consider appropriating a level of funding to the Puerto Rico Institute of Statistics that is commensurate with its important responsibilities. The Task Force also recommends that the **Institute of Statistics** continue to protect its independence and take all feasible steps to publish its products in English in addition to Spanish so these products can have the widest possible audience.

## 5. Support for Small Businesses

The Small Business Administration (SBA) promotes the interests of small businesses. SBA has 10 regional offices, and Puerto Rico—along with New York, New Jersey, and the U.S. Virgin

Islands—fall within [Region II](#), which is based in New York. SBA has a [district office](#) in Puerto Rico, which currently has 12 employees, and also covers the U.S. Virgin Islands.

On September 20<sup>th</sup>, the Task Force held a staff-level briefing with officials from the SBA. In addition, the Task Force received numerous submissions via the email portal from small business owners in Puerto Rico, from trade organizations representing small businesses on the island, and from national-level associations with an interest in SBA programs, namely the National Association of Development Companies and the National Association of Government Guaranteed Lenders.

Small firms play a significant, and often underappreciated, role in Puerto Rico's economy. According to the [Office of Advocacy](#) at the SBA, about 80 percent of private sector workers in Puerto Rico are employed at small establishments, which is slightly higher than the percentage in the U.S. mainland. Specifically, there are about 553,000 workers employed by about 45,000 small businesses. Each year for the last decade or so, the number of Puerto Rico establishments that started up (hired at least one employee for the first time) has been less than the number of establishments that exited (went from having at least one employee to having none, and remained closed for at least a year).

The SBA administers a range of programs to support small businesses, including capital access programs to help small firms obtain loans and other forms of capital; procurement programs to help small firms compete more effectively for federal government contracts; and entrepreneurial development programs to provide small firms with training and technical assistance.

There are presumably many small businesses in Puerto Rico operating in the informal economy, and therefore not subject to regulation or taxation. An objective of ongoing economic reforms in Puerto Rico should be to incentivize small firms to move from the informal to the formal economy, and it should be noted that SBA programs are only available to small firms operating in the formal economy.

#### **A. SBA Capital Access Programs**

Outside of its disaster assistance program, the SBA does not make direct loans to businesses. Instead, the agency typically guarantees loans made by approved private sector lenders to small firms that cannot obtain affordable credit elsewhere, or it makes direct loans to non-profit intermediaries that, in turn, make loans to small firms. The SBA's largest loan programs include the 7(a) loan guaranty program, the 504/Certified Development Company (504/CDC) loan guaranty program, and the Microloan program.

The Task Force believes that, for a variety of structural and other reasons, these programs are not producing satisfactory results in Puerto Rico. The Task Force believes that Congress and the SBA should take steps to improve the operation of these programs in Puerto Rico. The Task Force further believes that these steps should be targeted, should safeguard the effective operation and financing of these programs on the national level, and should be temporary in duration, *expiring when the Oversight Board established by PROMESA terminates*. The Task Force also believes these steps should be made applicable to the four other territories wherever feasible.

The Task Force makes the following recommendations:

- Under the 7(a) program, loans are made by SBA partners—mostly banks, but also some other financial institutions—and are partially guaranteed by the SBA. Proceeds from 7(a) loans may be used to establish a new business or to operate, acquire, or expand an existing business. The SBA’s current guaranty rate is 85 percent for loans of \$150,000 or less and 75 percent for loans greater than \$150,000. The Task Force recommends that **Congress** enact legislation to increase the guaranty rate and require a separate subsidy calculation for 7(a) loans made in Puerto Rico.
- The SBA generally assesses a fee on loans it guarantees under the 7(a) program, based on the loan’s maturity date and the dollar amount guaranteed. The lender initially pays the fee and may pass that expense on to the small business borrower at closing. The Task Force recommends that **Congress** direct the SBA to waive or reduce this fee in the case of a lender who makes an approved 7(a) loan to a borrower located in Puerto Rico.
- The 504/CDC loan guaranty program utilizes Certified Development Companies, which are private, nonprofit corporations established to contribute to economic development within their communities. Under the 504/CDC program, a commercial lender provides up to 50 percent of the financing, the CDC provides up to 40 percent of the financing (by issuing SBA-guaranteed debentures), and the small business contributes at least 10 percent of the financing—essentially a “down payment.” The Task Force recommends that, in the case of small businesses in Puerto Rico, **Congress** consider reducing the small business contribution and increasing the CDC contribution.
- Under the 504/CDC program, the SBA is authorized to charge CDCs five fees to help recoup the SBA’s expenses, including a participation fee. For their part, CDCs are authorized to charge borrowers a variety of fees, including a processing fee. The Task Force recommends that Congress direct the SBA to waive the participation fee that the SBA charges to CDCs located in Puerto Rico and/or to waive the processing fee that those CDCs charge to borrowers on the island.

- Under the Microloan program, the SBA provides direct loans to qualified nonprofit intermediary lenders that, in turn, provide loans of up to \$50,000 to small firms. Under current law, an intermediary in the Microloan program may not borrow more than \$750,000 in the first year of participation in the program and, in later years, the intermediary's obligation to the SBA may not exceed an aggregate of \$5 million. The Task Force recommends that **Congress** consider increasing that aggregate limit in the case of intermediaries located in Puerto Rico.
- In Fiscal Year 2016, the SBA received \$25 million in appropriations from Congress to make grants to Microloan intermediaries to provide Microloan borrowers and prospective borrowers with technical assistance. Under current law (known as the "25/75 rule"), no more than 25 percent of Microloan technical assistance grant funding received by an intermediary from the SBA may be used by the intermediary to provide pre-loan assistance (assistance to a prospective Microloan borrower), as opposed to post-loan assistance (assistance to an approved Microloan borrower). The Task Force recommends that **Congress** authorize an intermediary in the Microloan program to use more than 25 percent of its SBA-provided technical assistance grants on pre-loan assistance if the intermediary provides at least 25 percent of its loans to small firms in Puerto Rico.
- Should the new lending authority recommended in this section be enacted, the Task Force recommends that the **SBA** and the **Government Accountability Office** conduct regular and rigorous oversight of the effectiveness of this expansion.

## B. SBA Procurement Programs

The federal procurement process is the process whereby federal agencies acquire supplies and services for the agency's use or benefit. Government-wide and agency-specific goals for the percentage of contract and subcontract dollars awarded to small businesses have long been part of the federal procurement process. Congress has enacted, and the SBA administers, various programs to help small firms obtain and perform federal contracts and subcontracts. These include the 8(a) program for businesses owned by persons who are socially and economically disadvantaged, the Historically Underutilized Business Zone (HUBZone) program, the Women-Owned Small Business program, and the Service-Disabled Veteran-Owned Small Business program. By some metrics, Puerto Rico ranks low with respect to its participation in the federal procurement process.<sup>68</sup>

---

<sup>68</sup> According to the 2016 edition of the [Annual Review of Government Contracting](#), federal spending on procurement contracts totaled \$439.6 billion in Fiscal Year 2015. The Annual Review includes a table that ranks all 56 U.S. jurisdictions—the 50 states, the District of Columbia, and the five territories—by the total dollar value of federal contracts performed within each jurisdiction in Fiscal Year 2015. Puerto Rico ranks 50<sup>th</sup>, with \$430.6 million—\$307 million in defense contracts and \$123.6 million in non-defense contracts—performed on the island. The three states and three territories that fall below Puerto

The Task Force makes the following recommendations:

- The Task Force recommends that **Congress** consider establishing a contracting preference for small businesses in Puerto Rico with respect to federal contracts performed in Puerto Rico.<sup>69</sup>
- The SBA administers a mentor/protégé program. The program provides benefits to both the mentor firm and the protégé firm. In the case of the protégé, the relationship is designed to help the protégé firm better compete for federal contracts and subcontracts, including through joint venture arrangements with the mentor firm, and to otherwise enhance the capabilities of the protégé firm. Mentor firms can be businesses of any size that are in good financial standing and can impart knowledge to the protégé firm regarding general business operations and government contracting. Protégé firms must meet certain criteria as well. Typically, a mentor has one protégé at a time, but can have up to two or three if the mentor can demonstrate that the additional relationship(s) will not adversely affect the development of any of the protégé firms. Current federal law prohibits a mentor from having more than three protégés. The Task Force recommends that **Congress** authorize an exception to this three-protégé rule if the protégé firms are located in Puerto Rico or another territory.

---

Rico each has a smaller population than Puerto Rico. When the total dollar value of federal contracts performed in each jurisdiction is calculated on a per capita basis, Puerto Rico ranks 55<sup>th</sup>, ahead of only American Samoa. Furthermore, according to the [Federal Procurement Data System](#), of the 571 federal contracts that were performed in Puerto Rico in Fiscal Year 2015, 346 (approximately 61 percent) were awarded to firms located outside of Puerto Rico. The Task Force selected three states to serve as points of comparison, and asked CRS to run the searches of the Federal Procurement Data System. Of the 30,501 federal contracts performed in Oregon—which has a similar-sized population to Puerto Rico—in Fiscal Year 2015, 5,445 (18 percent) were awarded to firms located outside of Oregon. Of the 23,005 federal contracts performed in Mississippi in Fiscal Year 2015, 7,321 (32 percent) were awarded to firms located outside of Mississippi. Of the 96,463 federal contracts performed in Washington State in Fiscal Year 2015, 13,271 (14 percent) were awarded to firms located outside of Washington.

<sup>69</sup> Congress has the authority to require federal agencies to preference local contractors in connection with the awarding of federal contracts under certain circumstances, and Congress has exercised that authority on occasion. For example, the Robert T. Stafford Disaster Relief Act establishes a contracting preference for “organizations, firms, and individuals residing or doing business primarily in the area affected by [a] major disaster or emergency.” In addition, Section 15 of the Small Business Act requires that federal agencies give “priority” to small businesses that perform a substantial proportion of the production “within areas of concentrated unemployment or underemployment or within labor surplus areas” when setting aside contracts for small businesses. The Task Force is concerned that, on a per capita basis, the total dollar value of federal contracts performed in Puerto Rico is less than in any U.S. jurisdiction other than American Samoa. The Task Force is also concerned that, of the small number of federal contracts that are performed in Puerto Rico, about 6 of every 10 are awarded to firms outside of Puerto Rico.

### C. Small Business Innovation Research and Technology Transfer Programs

The Small Business Innovation Research (SBIR) program is designed to increase the participation of small innovative companies in federally-funded research and development. Federal agencies with extramural R&D budgets of \$100 million or more set aside a portion of these funds to finance an agency-run SBIR program that makes competitive awards to small businesses. Currently, 11 federal agencies participate in the SBIR program. Another competitive grant program, the Small Business Technology Transfer (STTR) program, facilitates the commercialization of university and federal R&D by small companies. Federal agencies with extramural R&D budgets of \$1 billion or more set aside a portion of these funds to finance an agency-run STTR program. Currently, five agencies participate in the STTR program. The SBA helps to coordinate the SBIR and STTR programs.

As of Fiscal Year 2014, federal agencies had made more than 133,000 awards totaling \$33.7 billion under the SBIR and STTR programs. However, according to the SBA's [website](#), Puerto Rico firms have received only 30 awards (26 SBBR awards and 4 STTR awards) totaling \$5.5 million, and no firms in any other territory have received any awards. Each state has received many more awards than Puerto Rico. Particularly in light of the number of science, technology, engineering and mathematics (STEM) professionals in Puerto Rico, the paucity of SBBR and STTR awards to small firms on the island is concerning.

In addition, the SBA administers the Federal and State Technology (FAST) partnership program, a competitive grant program that aims to help socially and economically disadvantaged firms compete in the SBIR and STTR programs. The program began in Fiscal Year 2001, expired at the end of Fiscal Year 2005, and was reestablished in Fiscal Year 2010. Pursuant to the FAST program, the SBA provides annual awards to state and local economic development agencies, business development centers, and colleges and universities, who use this funding to provide assistance to science-driven and technology-driven small businesses, including assistance to help them compete for SBIR and STTR awards. FAST grantees are required to meet a local matching requirement, which ranges from 50 cents for every \$1 in federal funding received (in the case of states and territories, such as Puerto Rico, with the fewest SBIR and STTR awards) to \$1 dollar for every \$1 in federal funding (in the case of states and territories with the most SBIR and STTR awards). Since the FAST program was reestablished in 2010, two Puerto Rico entities have received grants—the InterAmerican University of Puerto Rico and the Puerto Rico Trade and Export Company, a government-owned corporation. However, in Fiscal Year 2016, no Puerto Rico entity was awarded a FAST grant.

The Task Force makes the following recommendation:

- The Task Force recommends that **Congress** require the SBA to make an annual FAST partnership grant to a Puerto Rico grantee, and to waive the local matching requirement. If the SBA cannot find a suitable grantee, the Task Force recommends that Congress require the SBA to use the funding to help small businesses in Puerto Rico navigate the SBIR and STTR process, from application, to award, to successful completion of each phase of the program.

#### **D. SBA Disaster Assistance**

The SBA provides assistance to help individuals and businesses affected by disasters. Assistance is provided in the form of loans that must be repaid, rather than grants. As distinct from the SBA's other lending programs, disaster assistance loans are made directly by the SBA to the borrower.

Under current law, the term “disaster” means a “sudden event which causes severe damage.” It can include events like hurricanes, earthquakes, tornadoes, fires, floods, droughts, oil spills, and civil disorders.<sup>70</sup> The SBA's disaster loan program includes economic injury disaster loans (EIDLs). EIDLs are available to businesses located in a declared disaster area, that have suffered substantial economic injury, are unable to obtain credit elsewhere, and are defined as small by SBA size regulations, which vary from industry to industry. Substantial economic injury occurs where “the business concern is unable to meet its obligations as they mature or to pay its ordinary and necessary operating expenses.” The maximum loan amount for an EIDL is \$2 million. Loan proceeds can be used for working capital necessary to enable the business to alleviate the specific economic injury and to resume normal operations. The loan can have a maturity of up to 30 years and has an interest rate of 4 percent or less.

Over the past year, the United States, including Puerto Rico and other territories, has been adversely affected by Zika, a mosquito-borne virus that has been linked to birth defects and other severe health problems. To date, three U.S. territories—Puerto Rico, the U.S. Virgin Islands, and American Samoa—and two states—Florida and Texas—have experienced locally-acquired cases of Zika, and nearly every state and territory has experienced travel-associated cases of Zika. Puerto Rico is, by far, the most affected U.S. jurisdiction. According to the [Centers for Disease Control and Prevention \(CDC\)](#), as of early December, there were over 33,000 confirmed Zika cases in Puerto Rico. The Puerto Rico Department of Health has [placed](#) the number of confirmed cases at over 35,000, including approximately 2,800 pregnant women, and the number of presumed cases at about 65,000. According to the [CDC](#), there are about 800 locally-transmitted cases in the U.S. Virgin Islands, about 185 locally-transmitted cases in Florida (plus

---

<sup>70</sup> See 3(k)(1) of the Small Business Act.

about 785 travel-associated cases), about 55 locally-transmitted cases in American Samoa, and one locally-transmitted case in Texas.

In response to this unprecedented outbreak, the CDC took the equally unprecedented step of issuing Level 2 travel advisories for U.S. citizens traveling domestically to [Puerto Rico](#), the [U.S. Virgin Islands](#), [American Samoa](#), and parts of [Miami-Dade County, Florida](#).<sup>71</sup> These Zika-related travel advisories have had an adverse economic impact, particularly in the travel and tourism sector, although it is difficult at this time to estimate the impact with precision.

- The Task Force recommends that **Congress** amend the definition of “disaster” in the Small Business Act to encompass “communicable diseases for which the federal government issues a travel alert or travel warning” in order to authorize the SBA, at the request of the governor of an affected U.S. state or territory, to issue a disaster declaration and make economic injury disaster loans (EIDLs) available to help small firms in that state or territory recover from any substantial economic injuries they have experienced as a result of health-related travel advisories, such as those issued by the CDC in connection with Zika.<sup>72</sup>

## 6. Supplemental Security Income

The Supplemental Security Income (SSI) program was enacted in 1972 and took effect in 1974.<sup>73</sup> SSI, which is administered by the Social Security Administration (SSA), is a cash assistance program that provides monthly benefits directly to low-income aged, blind, or disabled persons in the 50 states, the District of Columbia, and one U.S. territory—the Northern Mariana Islands.

To receive SSI benefits based on age, an individual must be at least 65 years old. To receive SSI benefits based on disability, an individual must meet the same definition of disability that applies under the Social Security Disability Insurance (SSDI) program. To receive SSI benefits based on blindness, an individual must have visual impairments meeting certain criteria. In addition to age, disability, or blindness, an individual must meet income and resource tests to qualify for SSI benefits.

Congress has not extended the program to four of the five U.S. territories—Puerto Rico, the United States Virgin Islands, Guam, and American Samoa. Instead, Puerto Rico, the U.S. Virgin

---

<sup>71</sup> CDC Travel Health Notice types are: Watch Level 1 (practice usual precautions); Alert Level 2 (practice enhanced precautions); and Warning Level 3 (avoid nonessential travel).

<sup>72</sup> See S. 3301, the Small Business Relief from Disease Induced Economic Hardship Act (114<sup>th</sup> Congress; Sen. Rubio).

<sup>73</sup> See Social Security Amendments of 1972 (P.L. 92-603).

Islands, and Guam participate in a federal program called Aid to the Aged, Blind and Disabled (AABD), which used to apply nationwide until it was replaced by the SSI program in the 50 states and the District of Columbia. American Samoa is not currently eligible to participate in either SSI or AABD.

While the SSI program is administered by SSA, the AABD program is administered by the Administration for Children and Families (ACF) within the U.S. Department of Health and Human Services. The AABD program operates as an annual grant, with the federal government providing funding to the local territory government, which in turn distributes it to eligible individuals. In the case of Puerto Rico, ACF provides the annual AABD grant to the Puerto Rico Department of the Family, which then distributes it to eligible individuals. Pursuant to Section 1118 of the Social Security Act, the AABD program includes a 25 percent territory government matching requirement, meaning that for every \$100 in AABD benefits, the government of Puerto Rico must provide \$25. There is a 50 percent territory government matching requirement with respect to administrative, as distinct from assistance, expenditures; for every \$100 the government of Puerto Rico spends to administer the AABD program, it is reimbursed \$50 by the federal government. By contrast, the SSI program has no state government matching requirement and the federal government pays the entire cost of the program, although certain state governments and the District of Columbia government voluntarily choose to provide a supplement to the federal benefit.

Puerto Rico and the other territories that participate in AABD are each subject to an overall annual federal funding cap set forth in Section 1108 of the Social Security Act. The four federal programs subject to the Section 1108 cap are: (1) the AABD program under Titles I, X, XIV, and XVI of the Social Security Act; (2) the Temporary Assistance for Needy Families (TANF) program under Title IV-A of the Social Security Act; (3) various child welfare funding streams under Title IV-E of the Social Security Act; and (4) the so-called Matching Grant under section 1108(b) of the Social Security Act. Section 1108(b) matching grants, which include a 25 percent territory government matching requirement, may be used for TANF, including child care, and/or Title IV-E programs.

The annual Section 1108 cap for Puerto Rico is \$107,255,000, and has not been increased since enactment of the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 (P.L. 104-193). The government of Puerto Rico decides how to use the federal funds among the four programs that are subject to the Section 1108 cap. However, the TANF program—an annual block grant—is capped at \$71,562,501 for Puerto Rico pursuant to Section 403 of the Social Security Act. A territory may request funds less than its TANF cap and substitute claims from the other three programs to fill the deficit. In other words, there are two caps that operate in tandem with respect to the territories: the first is applicable to the cumulative amount of the four programs (the Section 1108 cap) and the second is applicable to the maximum amount of

the TANF grant (the Section 403 cap). The two caps are not adjusted for inflation and have remained at their current levels since Fiscal Year 1997. The effective funding cap after applying the basic TANF block grant is \$35,692,499: \$107,255,000 - \$71,562,501.

Based on a 2014 GAO [report](#), and on information supplied to the Task Force by ACF, the federal government provides approximately \$24 to \$26 million annually to the Puerto Rico Department of the Family under the AABD program, which is used to provide benefits to approximately 34,000 to 38,000 individuals, who receive an average monthly benefit of approximately \$74 to \$77 per recipient, 25 percent of which is government of Puerto Rico funding.<sup>74</sup>

The GAO calculated that, if Puerto Rico were to be included in SSI, Puerto Rico beneficiaries would directly receive between \$1.5 billion and \$1.8 billion per year in federal funding (compared to the current \$24-\$26 million under AABD), 300,000 to 350,000 individuals would receive benefits (compared to the current 34,000-38,000 under AABD), and the average monthly benefit would be around \$540 (compared to \$74-\$77 under AABD). Under SSI, the government of Puerto Rico would have no matching requirement for benefit payments or administrative costs.

Over the years, numerous bills have been introduced in Congress to extend the SSI program to Puerto Rico and the other territories that are excluded from the program.<sup>75</sup>

Some argue against including Puerto Rico and the other territories in the SSI program, at least in part because such inclusion would require substantial new federal outlays through mandatory appropriations from the general fund, yet beneficiaries of the outlays would include residents of the territories who do not pay into the general fund because Congress has exempted residents of Puerto Rico and the other territories from paying federal taxes on income earned within their respective territories. Of course, this argument would apply with equal force in the case of the Northern Mariana Islands, a territory to which Congress has extended the SSI program.

Others argue that it is not appropriate to exclude U.S. citizens living in the territories from the SSI program, especially considering that residents of the territories can simply relocate to the states and obtain full SSI benefits, and that virtually none of the 8.3 million SSI recipients earns sufficient income to owe federal income taxes.

---

<sup>74</sup> As a point of comparison, the average monthly AABD benefit in Guam is \$150, the average monthly AABD benefit in the U.S. Virgin Islands is \$176, the average monthly SSI benefit in the Northern Mariana Islands is \$591, and the average monthly SSI benefit nationwide is \$540.

<sup>75</sup> See, e.g., H.R. 1822, the Supplemental Security Income Equality Act (114<sup>th</sup> Congress; Rep. Pierluisi).

Some argue that SSI subjects beneficiaries to earnings and asset tests, which provide disincentives to saving and work activities. Disincentives to work would impose further labor-market challenges in Puerto Rico, given the already poor labor force participation rate.

The Task Force makes the following recommendation:

- The Task Force believes that it is important for Congress to debate the adequacy of the AABD program in Puerto Rico. The Task Force reviewed the historical record and was unable to identify a hearing conducted in the House or the Senate on this issue. The Task Force recommends that **Congress** examine the costs and benefits of either: (1) including Puerto Rico and the other territories in the SSI program with full benefits; (2) including Puerto Rico and the other territories in the SSI program with reduced benefits; (3) increasing the annual AABD grant provided to Puerto Rico and the other territories; (4) indexing the AABD and TANF caps to inflation; or (5) maintaining current law. In any examination, incentives to work should be considered.

The Task Force found it challenging to obtain up-to-date, publicly-available information about the operation of the AABD program in Puerto Rico, including basic information about the number of AABD beneficiaries, eligibility requirements for receiving AABD benefits, the average monthly AABD benefit, and the differences between the AABD program and the SSI program. As a result, the Task Force asked CRS to prepare a memorandum on this subject, and the Task Force has made that memorandum available to the public.<sup>76</sup>

The Task Force makes the following recommendation:

- The Task Force recommends that the **Administration for Children and Families**, working in conjunction with the Puerto Rico Department of Family, make publicly available—ideally on its website—a document that provides an up-to-date, detailed description of the AABD program in Puerto Rico and the other territories, in order to help federal policymakers better assess the AABD program.

## 7. U.S. Department of Commerce

The Secretary of the U.S. Department of Commerce made a written submission to the Task Force. On October 28<sup>th</sup>, the Task Force held a staff-level briefing with officials from the Office

---

<sup>76</sup> See William R. Morton, [Cash Assistance for the Aged, Blind, and Disabled in Puerto Rico](#), Congressional Research Service, October 26, 2016; see also Robin Respaut, [Deserted Island: The Disabled in Puerto Rico Fend for Themselves After Decades of U.S. Neglect](#), Reuters, December 9, 2016.

of the Secretary, the Bureau of Economic Analysis, the International Trade Administration, the Economic Development Administration, and the Minority Business Development Agency.

### A. Bureau of Economic Analysis

The Bureau of Economic Analysis (BEA) prepares and publishes a wide variety of economic statistics. BEA [produces](#) a quarterly estimate of U.S. gross domestic product (GDP), which covers only the 50 states and the District of Columbia, not the five U.S. territories. In addition, BEA produces quarterly GDP estimates for [each of the 50 states and the District of Columbia](#). Moreover, since 2010, the BEA has been [producing](#) annual GDP estimates for each U.S. territory other than Puerto Rico, reaching back in time to cover 2002 to 2014. In recent years, these territory estimates have been expanded to cover GDP by industry and compensation by industry. The GDP estimates for the four territories are calculated by BEA pursuant to a Statistical Improvement Program funded by the Office of Insular Affairs (OIA) in the U.S. Department of the Interior, which has jurisdiction over the territories other than Puerto Rico.

In late 2010 and early 2011, pursuant to an August 2010 request made by the Secretary of the Puerto Rico Department of Economic Development and Commerce to the U.S. Secretary of Commerce and a recommendation contained in the March 2011 report by the President’s Task Force on Puerto Rico, the BEA began an effort to help the government of Puerto Rico modernize its economic statistics programs. In the autumn of 2011, BEA produced a [report](#) describing its efforts and making recommendations, including the recommendation that Puerto Rico change its featured measure of production from GNP to GDP.<sup>77</sup> As a consequence of the change of administration in Puerto Rico in 2013, BEA stopped receiving cooperation from local officials and was unable to continue its provision of technical assistance for a period of years, and did not resume its work until 2015. In total, BEA estimates that it has spent \$350,000 in direct support to Puerto Rico, which it funded out of its core budget.

The Task Force makes the following recommendations:

- The Bureau of Economic Analysis currently publishes GDP estimates for each state, the District of Columbia, and every territory other than Puerto Rico. The Task Force supports BEA’s efforts to help the government of Puerto Rico modernize its economic statistics

---

<sup>77</sup> As [described](#) by BEA: “GDP is the market value of goods and services produced by labor and property within a country’s (or territory’s) borders, regardless of nationality. GNP is the market value of goods and services produced by labor and property supplied by resident producer units, regardless of where they are located. For GNP, as long as the labor and property are supplied by Puerto Rican residents, they may be located either in Puerto Rico or abroad. GDP refers to production taking place in Puerto Rico. It is, therefore, the appropriate measure for much of the short-term monitoring and analysis of the Puerto Rican economy. In particular, GDP is consistent in coverage with indicators such as employment, industry output, and investment in equipment and structures.”

programs, including the methods used to measure the island's GDP (and GNP). However, the Task Force recommends that **BEA** should calculate GDP for Puerto Rico, just as BEA does for every other U.S. jurisdiction. The Task Force recognizes that a transition period will likely be required, during which BEA and the government of Puerto Rico may need to share data collection and calculation responsibilities pursuant to a hybrid model. The Task Force further recommends that, in the same way that the U.S. Department of Interior is funding BEA's efforts to estimate GDP for each of the smaller territories, the federal government should fund BEA's efforts to calculate GDP for Puerto Rico. Finally, the Task Force believes that BEA's longer-term objective should be to include the U.S. territories (collectively, home to about 3.8 million people), alongside the states and the District of Columbia, in BEA's *national-level* GDP estimates, which will require the territory-level GDP data to meet all of BEA's quality standards.

## **B. International Trade Administration**

The International Trade Administration (ITA) seeks to boost foreign direct investment in the United States (including its territories) through the [SelectUSA](#) program and other programs; to help U.S. companies (including companies in the territories) increase their exports to foreign markets through the [National Export Initiative](#) and other programs; and to promote travel by foreign nationals to the United States (including its territories). ITA's National Travel and Tourism Office (NTTO) supports the U.S. travel and tourism industry. It is the principal liaison in the federal government to [Brand USA](#), the non-profit, public-private partnership that serves as the destination marketing organization for the United States, including all territories. Brand USA aims to attract international visitors, which constitute the largest services export for the United States, through advertising campaigns; providing information on required documents, fees, and procedures; correcting misperceptions about U.S. entry policies; and assisting both rural and urban areas in bringing international tourists.

ITA does *not* promote domestic investment (including investment by stateside companies in Puerto Rico), interstate commerce (including commerce between the states and Puerto Rico) or interstate travel (including travel between the states and Puerto Rico).

With respect to foreign direct investment, notwithstanding Lufthansa Technik's 2014 [decision](#) to open a maintenance, repair and overhaul (MRO) facility in Puerto Rico, an achievement for which ITA deserves significant credit, foreign direct investment (FDI) in Puerto Rico appears to be minimal in recent years, based on state-by-state data from 2014 and 2015 in BEA's [Survey of New Foreign Direct Investment in the United States](#).<sup>78</sup> It is difficult to measure FDI in Puerto Rico, since the government of Puerto Rico has not published relevant data since Fiscal Year

---

<sup>78</sup> See [BEA's New Foreign Direct Investment in the United States, 2014 and 2015](#).

1984.<sup>79</sup> The Task Force is advised that BEA is working to help the government of Puerto Rico resume collection of these data after a 30-year hiatus.

With respect to exports, the situation appears challenging as well. According to the U.S. Census Bureau's foreign trade statistics, [exports from Puerto Rico](#) to foreign nations totaled \$20.4 billion in Calendar Year 2015, while the Puerto Rico Institute of Statistics places the estimate somewhat lower at \$17.5 billion. Either way, this is a significant sum, but it is clear that the vast majority (over 90 percent) of these exports are from foreign subsidiaries of U.S. companies operating in the pharmaceutical product, organic chemical, and medical equipment and supply industries. Apart from these large multinational firms, Puerto Rico-based companies appear to export relatively little to foreign countries. Small firms seem to fare particularly poorly. In the November 2016 [Puerto Rico Small Business Survey](#), released by the New York Federal Reserve Bank, 81 percent of firms surveyed say they derive no revenue from exports, 14 percent of firms derive less than 25 percent of their revenue from exports, 3 percent of firms derive 25 to 50 percent of their revenue from exports, 0 percent of firms derive 51 to 75 percent of their revenue from exports, and 2 percent of firms derive more than 75 percent of their revenues from exports. Moreover, based on the ambiguous phrasing of the question posed, it is possible—perhaps probable—that surveyed firms included sales to customers in the U.S. mainland within the definition of “exports.” If so, the actual export figures may be even worse than the survey suggests.

With respect to travel and tourism, they are an important component of Puerto Rico's economy, currently constituting about [7 percent](#) of GNP. However there is clearly room for significant improvement, particularly as it relates to visitors from foreign nations. According to the [government of Puerto Rico](#), the number of annual visitors to Puerto Rico over the last decade (2006 to 2015) has averaged about 4.6 million. In 2015, there were about 5.0 million visitors who spent a total of \$3.8 billion. Of those 5.0 million visitors, 3.5 million (70 percent) were “tourists” and 1.5 million (30 percent) were “excursionists” who arrived to the island on cruise ships. Of the 3.5 million tourists, 3.1 million (88 percent) came from the mainland U.S. and only 473,000 (12 percent) came from foreign countries.<sup>80</sup>

Based on the observations above, Puerto Rico is in significant need of the various services that ITA provides related to FDI, exports, and travel and tourism.

On the one hand, Puerto Rico should be an attractive location for capital investors (as well as for tourists). The island has natural beauty, a superb climate, a rich culture, and a fascinating history. Puerto Rico is part of the U.S. banking, currency, trade, and legal systems. Puerto Rico

---

<sup>79</sup> See [Puerto Rico Planning Board, Balance of Payments 2015](#), at page 19, note a.

<sup>80</sup> See [Statistical Appendix](#), page A-38.

has access to U.S. markets, including—until recently—financial markets. It has free flows of labor and capital and participates in the U.S. trade regime with the rest of the world. It is strategically located in the Caribbean region, approximately 1,000 miles from both the southern United States and the Andean region of South America. Although Puerto Rico’s elementary and secondary public school system requires reform, and migration to the states has taken a considerable toll on the available labor pool, both skilled and unskilled, there is still a large pool of well-educated professionals on the island. According to the Census Bureau, of Puerto Rico’s population age 25 and older, 30.5 percent have a college or graduate degree, virtually the same percentage as in the states. Ninety-five percent of Puerto Rico residents speak Spanish at home and, while 77 percent profess to speak English “less than very well,” there are many fully bilingual or proficient English speakers, particularly among the island’s youth.

On the other hand, there are number of factors in Puerto Rico that tend to inhibit capital investment, including the government’s fiscal challenges; poor financial reporting; the high cost of electricity and other utilities; a burdensome permitting system and other bureaucratic issues; a relatively high level of violent crime; labor market rigidities; complicated and often idiosyncratic tax policies; relatively weak infrastructure; and a high degree of politicization, which causes even productive investments, policies, and programs to be halted by one political party because they were instituted under the other political party.

The Task Force makes the following recommendations:

- The Task Force was advised by multiple federal agencies that the government of Puerto Rico has yet to establish a comprehensive economic development strategy that exploits the island’s many comparative advantages, both intrinsic and acquired, and that endures after power passes from one local party to the other. The Task Force recommends that the **government of Puerto Rico** take this constructive criticism to heart.
- The Task Force recommends that the **International Trade Administration** take all reasonable steps to educate stakeholders in Puerto Rico about the multiple services that ITA provides, including by holding educational or technical assistance events in Puerto Rico. The Task Force is especially concerned about the relatively low level of export activity on the part of Puerto Rico firms, particularly small firms, and believes there is room for significant improvement in this area, if properly facilitated by ITA.
- The Task Force was advised by federal agencies that the government of Puerto Rico has a history of opening and operating trade offices in other nations to promote foreign direct investment, trade, and other commercial arrangements. The federal agencies observed that, while there is absolutely nothing inherently wrong with this practice, the government of Puerto Rico may not fully appreciate that it can obtain these services from the International

Trade Administration at little to no cost and with (presumably) equal or better results. The Task Force recommends that the **government of Puerto Rico** take additional steps to leverage the available resources and programs of ITA and carefully consider whether the economic benefits of operating trade offices in other nations outweigh the financial costs, particularly if the sought-for benefits can be realized by tapping into existing ITA resources and expertise.

- Adhering to the principle that it is difficult to improve what you cannot measure, the Task Force recommends that the **government of Puerto Rico** collect and publish annual statistics about foreign direct investment on the island, making sure to disaggregate the data so that investment from the U.S. mainland and investment from foreign nations are tabulated separately. The Task Force further recommends that any federal government statistical products that provide state-by-state data on foreign direct investment also include equivalent data on Puerto Rico and the other territories.
- The [United States Travel and Tourism Advisory Board](#) (TTAB) serves as the advisory body to the Secretary of Commerce on matters relating to the travel and tourism industry in the United States. The Board consists of up to 32 members appointed by the Secretary of Commerce, who typically serve for a two-year term. Members represent companies and organizations in the travel and tourism industry from a broad range of products and services, company sizes and geographic locations. The [current board](#) includes individuals from many states, including the president of the American Indian Alaska Native Tourism Association. The Task Force recommends that the **Secretary of Commerce** take reasonable steps to appoint at least one member who has special expertise on tourism in Puerto Rico and/or the other territories.
- The Task Force believes that more can be done to increase the relatively low level of travel and tourism in Puerto Rico by foreign nationals. The Task Force notes that the ITA's National Travel and Tourism Office (NTTO) conducts a [Survey of International Air Travelers](#) (SIAT). The SIAT provides key market intelligence on the characteristics of visitors to a U.S. jurisdiction. This information can then be used by the jurisdiction's tourism promotion body to develop targeted marketing strategies to attract visitors and help ensure they obtain the experience they desire. The Task Force has been advised that, despite efforts by NTTO, the SIAT is not conducted at the San Juan International Airport, evidently because of opposition from the airport's private operator. The Task Force believes the SIAT could provide valuable information to help Puerto Rico increase tourism from foreign nationals, and recommends that the **airport's private operator**, the **Puerto Rico Ports Authority**, and the **Puerto Rico Tourism Company** work with NTTO with the goal of authorizing the SIAT to be conducted at the San Juan International Airport on mutually-acceptable terms. The distribution and collection of surveys would be completed by the Puerto Rico Tourism Company (a public corporation), the airport staff, or a private sector company from Puerto

Rico. The NTTO would supply the questionnaire (available in 12 languages) and pay for the entry, verification, processing, and publication of the data. The NTTO would provide the survey results to a lead contact in Puerto Rico, and prepare an annual “Overseas Visitors to Puerto Rico” report for use by the Puerto Rico Tourism Company and others.

### C. Economic Development Administration

The U.S. Economic Development Administration (EDA) [describes](#) itself as “the only federal government agency focused exclusively on economic development.” Through multiple competitive grant programs, the agency provides assistance to economically-distressed regions and areas.<sup>81</sup> In Fiscal Year 2016, the EDA received \$222 million for its programs and activities.

Between Fiscal Year 2010 and Fiscal Year 2015, EDA made over 4,100 grants totaling more than \$1.7 billion to applicants throughout the United States. In that time period, Puerto Rico applicants received 10 grants totaling \$6.2 million, among the lowest of all jurisdictions.<sup>82</sup>

In Fiscal Year 2010, EDA made a \$400,000 grant to the Puerto Rico Planning Board, which was used to develop a [Comprehensive Economic Development Strategy](#) (CEDS) for Puerto Rico. The CEDS was prepared by the CEDS Committee, which consists of representatives of the government of Puerto Rico, universities, non-profit organizations, and trade organizations. The EDA approved the 2010 CEDS, and approved updates to the CEDS made by the CEDS Committee in 2012 and 2014.<sup>83</sup> The CEDS Committee is currently in the process of preparing a new CEDS, which is expected to be released in early 2017, but could be delayed somewhat as a result of the forthcoming change in local administration. Unlike the 2010 CEDS, EDA is not funding this effort through a grant, but is providing technical assistance to ensure that the new CEDS complies with all EDA guidelines.

EDA has six regional offices. Puerto Rico is one of 16 jurisdictions covered by the Philadelphia Regional Office. The EDA’s Economic Development Representative for Puerto Rico is currently based in Philadelphia, not Puerto Rico. An Economic Development Representative provides a variety of services, including offering technical assistance to potential applicants for EDA funding, monitoring the implementation of EDA-funded projects by grantees, and interacting with the CEDS Committee.

---

<sup>81</sup> EDA’s main grant programs include: Public Works (funded at \$100 million in Fiscal Year 2016); Economic Adjustment Assistance (\$35 million); Partnership Planning Assistance (\$32 million); Regional Innovation Strategies (\$15 million); Trade Adjustment Assistance (\$13 million); and Technical Assistance (\$10.5 million).

<sup>82</sup> See EDA, Annual Reports to Congress for Fiscal Year 2010 to Fiscal Year 2015, available [here](#).

<sup>83</sup> EDA provided the Task Force with a copy of the 2010 and 2014 CEDS.

The Task Force makes the following recommendations:

- The Task Force is aware that EDA recently determined that its Economic Development Representative (EDR) for Puerto Rico can more effectively serve the island if the Representative is based in Puerto Rico, rather than in the Philadelphia Regional Office. The Task Force recommends to **EDA** that a Puerto Rico-based EDR begin work as soon as possible. The Task Force urges the Puerto Rico-based EDR to provide technical assistance to potential grantees and to identify projects on the island that may be suitable for EDA support. Similarly, the Task Force recommends to potential Puerto Rico-based applicants for EDA funding that they affirmatively seek technical assistance from EDA and incorporate feedback from EDA into their applications, a step that EDA says does not always occur. The Task Force believes that the ultimate objective should be to arrive at a point where the quantity of EDA grants to Puerto Rico-based applicants better corresponds with the size of Puerto Rico's population and the scale of its economic development needs.
- The Task Force was advised by multiple federal agencies that the government of Puerto Rico has yet to establish a comprehensive economic development strategy that exploits the island's many advantages. The 2017 Comprehensive Economic Development Strategy (CEDS) for Puerto Rico that the CEDS Committee is in the process of preparing, with technical assistance from EDA, could help in this regard. The Task Force recommends that the **CEDS Committee** obtain input from a diverse array of stakeholders, particularly from the private and non-profit sectors. The Task Force further recommends that that CEDS Committee, once the CEDS has been approved by EDA, make the CEDS available on-line and otherwise publicize the CEDS to stakeholders on the island, in the U.S. mainland, and abroad. The Task Force notes that, although the Puerto Rico Planning Board purports to provide a link to the current CEDS (last updated in 2014) on its website, the Task Force was unable to access the report. An economic development strategy document not accessible by the general public, potential and current investors in the island, and other stakeholders is of questionable utility, no matter how sound its contents might be.
- The Puerto Rico Department of Agriculture has advised the Task Force that over 80 percent of the food consumed in Puerto Rico is transported to the island from the U.S. mainland and from foreign countries. According to information provided to the Task Force, an extended disruption in maritime trade could result in Puerto Rico's supply of food being exhausted within a matter of weeks or less. The Task Force notes that, in Fiscal Year 2011, EDA made a \$100,000 Economic Adjustment Assistance grant to the Hawaii State Office of Planning to develop a plan to improve Hawaii's agricultural sector and food distribution systems, with Hawaii contributing \$100,000 in matching funds. In 2012, the Hawaii government released a three-volume report, with [Volume 1](#) entitled "Increased Food Security and Food Self-

Sufficiency Strategy.” The Task Force believes that a similar EDA-funded effort may be appropriate and valuable in the case of Puerto Rico and recommends to **EDA**, the **CEDS Committee**, and other stakeholders that they explore this possibility.

#### **D. Electronic Export Information**

Under 13 U.S.C. Chapter 9 (Section 301 to Section 307), the U.S. Census Bureau—within the U.S. Department of Commerce—is responsible for collecting and publishing export trade statistics. The Census Bureau has issued [regulations](#)—15 CFR 30—to fulfill this responsibility. Except in specified instances, these regulations require an exporter to provide Electronic Export Information (EEI), which includes the identity of the exporter and detailed information regarding the exported product. While the Census Bureau uses the EEI solely for statistical purposes, other federal agencies use EEI to prevent unauthorized exports. EEIs are generally filed electronically through the [Automated Export System \(AES\)](#). EEIs are completed and filed by either the exporter (known as the U.S. Principal Party in Interest, or USPPi) or by the maritime or air carrier (the freight forwarder) transporting the goods.

EEI filings are required for shipments between the United States (including its territories) and a foreign nation, although EEI filings are not generally required for shipments from the United States to Canada.<sup>84</sup> EEI filings are not required for shipments between one U.S. state and another U.S. state.

With respect to shipments between the 50 states and a U.S. territory, the situation is more complex. For example:

- EEI filings *are* required for shipments from the states to Puerto Rico, and *are* required for shipments from Puerto Rico to the states.<sup>85</sup>
- EEI filings *are* required for shipments from the states (or from Puerto Rico) to the U.S. Virgin Islands, but *are not* required for shipments from the U.S. Virgin Islands to the states (or to Puerto Rico).<sup>86</sup>
- EEI filings *are not* required for shipments between the states and American Samoa, Guam, or the Northern Mariana Islands.<sup>87</sup>

---

<sup>84</sup> See 15 CFR 30.36.

<sup>85</sup> See 15 CFR 30.2(a)(1)(i)(A) and (B).

<sup>86</sup> See 15 CFR 30.2(a)(1)(i)(C).

<sup>87</sup> See 15 CFR 30.2(d)(2).

The U.S. territories are not foreign countries, and Puerto Rico—unique among the five territories—is within “the customs territory of the United States.”<sup>88</sup> Trade between the states and Puerto Rico is therefore more accurately described as interstate commerce than international commerce.

The Task Force received a written submission from the Express Association of America, which consists of the four largest express delivery service providers in the world—Deutsche Post DHL Group, FedEx, TNT and United Parcel Service (UPS). The Express Association asserted the following:

Requiring EEI filings is tantamount to placing a boundary that separates Puerto Rico from the United States to the detriment of the Island’s economic well-being. The EEI filing requirement adds a cost which increases the price of many goods purchased in Puerto Rico and imposes an unnecessary burden on interstate commerce, restricting the flow of trade within the United States. As a result, some stateside companies simply decide not to ship their merchandise to Puerto Rico. The EEI requirement is equally burdensome on companies exporting from Puerto Rico, particularly for small and medium sized business which do not have large brokerage and customs compliance staffs to generate the data. [Bullet points in original removed].

The Task Force makes the following recommendation:

- The Task Force recommends that the **U.S. Department of Commerce**—in consultation with its internal departments and other stakeholders, such as the U.S. Census Bureau and the Bureau of Economic Analysis; other appropriate federal agencies; the Puerto Rico Institute of Statistics; the Puerto Rico Planning Board; and the trade community—conduct a thorough evaluation of its regulations requiring EEI filings for shipments between the states and Puerto Rico. The Task Force is concerned about the possible adverse impact that required EEI filings may have on commerce between the states and Puerto Rico. At the same time, as described elsewhere in this report, the Task Force is intent on ensuring that timely and reliable economic statistics are available for Puerto Rico. The Task Force has been advised by federal officials that elimination of the EEI requirement may (1) negatively impact the ongoing, joint federal-local effort to modernize the methodology used to calculate Puerto Rico’s gross domestic product (GDP) and other macroeconomic statistics, and (2) make it more difficult to measure trade between the states and Puerto Rico. As part of the recommended evaluation, the Department of Commerce should identify and weigh the

---

<sup>88</sup> See 19 CFR 101.1.

benefits and costs of required EEI filings. The Department should assess whether alternate datasets, such as the government of Puerto Rico's [SURI](#) system (Sistema Unificado de Rentas Internas), could be used with or without modification to achieve the same statistical objective, while imposing a lesser burden on commerce. The recommended examination should also attempt to quantify any economic benefits that would be achieved by eliminating the EEI filing requirement.

## **8. U.S. Department of the Treasury**

### **A. CDFI Fund**

The Community Development Financial Institutions Fund (CDFI Fund), an office within the Department of the Treasury, seeks to generate economic growth in low-income communities that lack access to capital, credit and financial services. On October 4<sup>th</sup>, the Task Force held a staff-level briefing with the director of the CDFI Fund to discuss the Fund's programs and whether they are having their intended effects in Puerto Rico.

The CDFI Fund administers a number of competitive programs that invest in, train, and otherwise support CDFIs, including the core CDFI program, the Bank Enterprise Award program, and the Capital Magnet Fund. CDFIs are banks, credit unions, loan funds, or venture capital providers that provide loans, investments, financial services, and technical assistance to individuals and businesses with the goal of promoting community development in underserved areas.<sup>89</sup>

Under the core CDFI program, the CDFI Fund provides two types of monetary awards through an annual competitive application process: financial assistance awards up to \$2 million and technical assistance awards up to \$125,000.<sup>90</sup> Under the Bank Enterprise Award (BEA) program, the CDFI Fund makes awards to FDIC-insured banks and thrifts on a competitive basis. BEA program awardees are recognized for increasing their investments in certified CDFIs and their activities in economically-distressed communities. BEA program awards are retrospective, rewarding applicants for activities they have already completed.<sup>91</sup> Under the Capital Magnet

---

<sup>89</sup> There are nearly 1,000 certified CDFIs operating nationwide, but only six based in Puerto Rico, all loan funds.

<sup>90</sup> Since the inception of the CDFI program in 1994, the CDFI Fund has made about 3,000 FA and TA awards to CDFIs, totaling about \$2 billion. The CDFI Fund has made a total of five FA awards and three TA awards to Puerto Rico-based CDFIs, totaling \$2.3 million, and has made no awards since 2009. At least 9 CDFIs based in the states have made investments in Puerto Rico as well.

<sup>91</sup> Since the inception of the BEA program in 1994, no FDIC-insured bank in Puerto Rico has applied for a BEA.

Fund, the CDFI Fund makes competitive grants to CDFIs and non-profit housing organizations to finance affordable housing and other community revitalization projects.<sup>92</sup>

In addition, the CDFI Fund administers the New Markets Tax Credit (NMTC) program, which utilizes Community Development Entities (CDEs). CDEs are financial intermediaries through which private capital flows from investors to a qualified business located in a low-income community. Specifically, CDEs use their authority to offer federal income tax credits to investors in exchange for the investors making equity investments in the CDE. The federal tax credit totals 39 percent of the original investment amount and is claimed over a period of seven years. Using the capital from these equity investments, CDEs can lend to and invest in businesses operating in low-income communities.<sup>93</sup>

While members of the Task Force agree on the ultimate goals of CDFI programs, members have varying views about the efficacy of the programs in achieving those objectives. In addition, some members of the Task Force have concerns about the adequacy of controls in CDFI programs.<sup>94</sup> Nevertheless, members of the Task Force agree that Puerto Rico should receive equitable opportunities under all CDFI Fund programs authorized and funded under current law.

The Task Force makes the following recommendations:

- The CDFI Fund website contains a “[Searchable Awards Database](#).” The database includes a user-friendly map. By clicking on any state or the District of Columbia, a visitor to the website receives a detailed summary of all CDFI Fund awards made to CDFIs and CDEs in that jurisdiction. Puerto Rico and the other territories are not included on the map, even though territory-based CDFIs and CDEs are eligible for all CDFI Fund programs. Similarly, the CDFI website contains a “[NMTC Allocatee States Served](#)” page, which features a map that also excludes Puerto Rico and the other territories. The Task Force recommends that the **CDFI Fund** update the maps on its website to include Puerto Rico and the other territories, and provide the same level of detailed award information for the territories that it provides for the states and the District of Columbia.

---

<sup>92</sup> No Puerto Rico-based CDFI or non-profit housing organization has received a Capital Magnet Fund award.

<sup>93</sup> Nationwide, there are approximately 6,000 certified CDEs, including 18 based in Puerto Rico. Beginning in 2002, the CDFI Fund has completed 13 NMTC allocation rounds. The Fund has made 1,032 allocation awards totaling \$50.5 billion in tax credit allocation authority. Puerto Rico-based CDEs have received three allocations, one for \$45 million in 2009, one for \$10 million in 2009, and one for \$70 million in 2016.

<sup>94</sup> See, e.g., [New Markets Tax Credit: Better Controls and Data Are Needed to Ensure Effectiveness](#), Government Accountability Office, July 10, 2014 (GAO-14-500).

- Although there are CDFIs based in the states that have made important investments in Puerto Rico, that does not diminish the need for additional Puerto Rico-based CDFIs that are familiar with Puerto Rico’s particular economic and social needs and are focused exclusively on community development on the island. Puerto Rico has among the fewest CDFIs per capita of any state, and *the* fewest CDFIs per capita when the population is limited to individuals living below the federal poverty level. The Task Force recommends that the **CDFI Fund** take all reasonable steps to increase the number of CDFIs in Puerto Rico and the other territories, consistent with the House Appropriations Committee’s language to that effect in the [report](#) accompanying the Financial Services and General Government Appropriations Act, 2017.<sup>95</sup> The Task Force further recommends that the CDFI Fund, as part of its Capacity Building Initiative, conduct at least one outreach event in Puerto Rico in the near future, something the Fund has not done to date. In addition, the Task Force recommends that the CDFI Fund continue its ongoing work with the U.S. Department of Commerce’s Minority Business Development Agency, the Federal Reserve Bank of New York, the Opportunity Finance Network (a member-based organization of CDFIs), and other stakeholders to expand the number of CDFIs in Puerto Rico and to improve their capacity to apply for, obtain and make optimal use of CDFI Fund awards. Finally, the Task Force notes that there are 11 credit unions in Puerto Rico that are insured by the National Credit Union Administration (NCUA) and that, in January 2016, the CDFI Fund and the NCUA signed a [memorandum of understanding](#) to streamline the process for low-income credit unions to be certified as CDFIs. The Task Force recommends that the CDFI Fund take steps to educate the 11 NCUA-insured credit unions in Puerto Rico about the potential benefits of becoming a certified CDFI and about the process that exists for low-income credit unions to become certified on an expedited basis.
- Puerto Rico has fared poorly under the NMTC program to date, particularly in light of the fact that it has a higher poverty rate and unemployment rate than any state, making it precisely the kind of economically-distressed jurisdiction that the NMTC program is designed to assist. The Task Force recognizes that this problem cannot be resolved from one day to the next, but rather requires determined efforts on the part of the CDFI Fund, current and potential Puerto Rico-based CDEs, and other stakeholders. The CDFI Fund indicated in a memorandum to the Task Force that the preference that the Fund provides to applicants who commit to making “innovative use” of its NMTC allocation “serves as an incentive” for applicants to invest in states and territories, like Puerto Rico, that have historically received lower levels of NMTC-supported investments. At this juncture, however, there is insufficient evidence to confirm that the “innovative use” preference is, in fact, having such an incentivizing effect. Therefore, the Task Force recommends that the **CDFI Fund** include in its annual NMTC program award report any examples of allocation awards that were

---

<sup>95</sup> See page 19.

advanced through the NMTC review process as a result of the “innovative use” criteria. By highlighting these success stories, the CDFI Fund could encourage future applicants to pursue development strategies in geographic areas that have been historically underserved by NMTC-supported investments as a means of being selected from a highly-competitive pool of applicants.

- The Task Force recommends that the **CDFI Fund** take steps to educate FDIC-insured banks in Puerto Rico about the potential benefits of applying for retrospective awards under the Bank Enterprise Award program, and reinvesting any award funding it receives into distressed communities on the island. The Task Force further recommends that the CDFI Fund take steps to educate Puerto Rico-based CDFIs about the Capital Magnet Fund.
- The director of the CDFI Fund is advised by a 15-member [Community Development Advisory Board](#).<sup>96</sup> Six Board members represent federal agencies, while nine are private citizens appointed by the President. Federal law requires that these nine individuals “be selected, to the maximum extent practicable, to provide for national geographic representation and racial, ethnic, and gender diversity.” No resident of Puerto Rico or any other territory has ever served on the Advisory Board. The Task Force believes that the lending and community development issues in the territories are unique in certain respects, and that CDFI Fund leadership could benefit from the counsel of an Advisory Board member with specialized expertise in this area. The Task Force recommends that the **CDFI Fund** make good-faith efforts to appoint an individual to the Community Development Advisory Board with personal experience and specialized expertise in the unique lending and community development issues facing U.S. territories.

## **B. Technical Assistance to the Government of Puerto Rico**

Beginning in Fiscal Year 2016, Congress has expressly authorized the U.S. Department of the Treasury to provide “technical assistance” to the government of Puerto Rico on “stabilizing and strengthening public financial management and financial management systems.”<sup>97</sup>

On October 11<sup>th</sup>, the Treasury Department provided a staff-level briefing for some, but not all, members of the Task Force. The Treasury Department indicated that it is currently using its technical assistance authority to help the government of Puerto Rico in the following five areas: (1) tax collection enforcement, (2) revenue forecasting and receipts estimation, (3) large taxpayer

---

<sup>96</sup> See 12 U.S.C. 4703.

<sup>97</sup> See Division E, Financial Services and General Government Appropriations Act, 2016, part of the [Consolidated Appropriations Act, 2016](#) (P.L. 114-113); see also [House Report 114-94](#), accompanying the Financial Services and General Government Appropriations Act, 2016, at page 11.

unit and general audit of taxpayers, (4) budget and cash management, and (5) information technology (tax administration).<sup>98</sup>

The Task Force makes the following recommendation:

- The Task Force recommends that **Congress** continue to provide the U.S. Department of the Treasury with the authority to provide technical assistance to the government of Puerto Rico, in order to help it stabilize and strengthen its financial management, financial management systems, and tax collection systems, with robust periodic reporting requirements. The Task Force recommends that the **Treasury Department** continue to provide technical assistance pursuant to this authority, and that the Treasury Department report to Congress on a regular basis regarding these efforts and the progress that is being made.

## 9. Investor Protection

On May 25, 2016, H.R. 5322, the [U.S. Territories Investor Protection Act of 2016](#), was introduced in the House of Representatives.<sup>99</sup> The bill amends Section 6(a)(1) of the Investment Company Act of 1940 to terminate an exemption for investment companies located in Puerto Rico or any other U.S. territory. Under current law, such companies are exempt from registration under the Act provided that their shares are sold solely to the residents of the territory in which they are located. The bill provides a three-year safe harbor for investment companies that currently enjoy this exemption. Additionally, the bill authorizes the Securities and Exchange Commission (SEC) to further delay the effective date (that is, the end of the exemption) for a maximum of three years following the initial three year safe harbor.

H.R. 5322 was unanimously approved by the House Committee on Financial Services on June 16, 2016.<sup>100</sup> On July 11<sup>th</sup>, the full House approved H.R. 5322 by voice vote. On September 9<sup>th</sup>, an identical companion bill to H.R. 5322, S. 3467, was introduced in the Senate.<sup>101</sup>

---

<sup>98</sup> The Chairman of the Task Force, who is also the Chairman of the Senate Finance Committee, which has oversight and authorization responsibilities with respect to the Treasury Department, expresses his view that Treasury officials have chosen not to provide briefings requested by the Chairman regarding use of this technical assistance authority, or to explain why the Treasury Department has signed confidentiality agreements with two component units of the government of Puerto Rico, or to substantively respond to questions put forward by the Chairman. The Chairman expresses his view that this lack of transparency and accountability does not serve Congress or the people of Puerto Rico.

<sup>99</sup> H.R. 5322 was introduced by Rep. Nydia Velázquez of New York.

<sup>100</sup> See [House Report 114-673](#).

<sup>101</sup> S. 3467 was introduced by Senator Robert Menendez of New Jersey and cosponsored by Senator Orrin Hatch of Utah.

The Task Force makes the following recommendations:

- The Task Force recommends that **Congress** pass the U.S. Territories Investor Protection Act of 2016. The Task Force believes that the original justification for the exemption of investment companies located in Puerto Rico and the other territories from the Investment Company Act of 1940 (namely, the logistical challenges associated with SEC personnel traveling to the territories in order to inspect investment companies) is no longer valid; that repealing this exemption will provide important protections for investors residing in the U.S. territories that they currently lack; and that the U.S. Territories Investor Protection Act of 2016 provides investment companies in the territories with sufficient opportunity to come into compliance, and therefore does not unduly burden those companies.
- Municipal securities are subject to rules set by the Municipal Securities Rulemaking Board (MSRB), a self-regulatory organization charged with regulating financial companies that sell, purchase and underwrite municipal securities. SEC Rule 15c2-12 requires that dealers, when underwriting certain municipal securities, ensure that the state or local government issuing the bonds agrees to disclose certain information to the MSRB on an ongoing basis. Timely disclosure helps investors make informed decisions about investments in municipal bonds, including instances in which material changes to an issuer's financial condition occur, and helps protect them against fraud involving the bonds. The Task Force observes that Puerto Rico has too often missed its continuing disclosure obligations to provide audited financial statements. Failure to meet such obligations may have contributed to an inability of all stakeholders to fully understand the nature and extent of Puerto Rico's economic and fiscal challenges in a timely manner. The Task Force encourages further debate in Congress about the efficacy of SEC and MSRB rules and regulations governing failures to meet disclosure requirements.

## 10. Public Safety

Violent crime in a jurisdiction harms quality of life, spurs migration, and hinders economic growth by creating an overall environment that is less conducive to business activity and investment.

According to the [FBI's Uniform Crime Reporting](#) program for 2015, Puerto Rico has a higher homicide rate—16.8 homicides per 100,000 inhabitants—than any U.S. state. The state with the highest homicide rate is Louisiana, at 10.3 homicides per 100,000 inhabitants. The number of homicides in Puerto Rico peaked in 2011, at 1,164—or 31.4 homicides per 100,000 residents. There was a steady downward trend in the following years, with 1,005 homicides in

2012, 902 homicides in 2013, 684 homicides in 2014, and 588 homicides in 2015.<sup>102</sup> However, the number of homicides in [2016](#) exceeds the number in 2015, with over 630 homicides having occurred as of mid-December.

Many, if not most, of the homicides and other violent crimes in Puerto Rico are connected to the international narcotics trade.<sup>103</sup> Puerto Rico is an important transshipment point for drug trafficking organizations transporting narcotics from South America, Central America and the Caribbean to the mainland United States. Puerto Rico is also a final destination point for narcotics.

The Task Force makes the following recommendation:

- The Task Force recommends that **Congress** continue to exercise its oversight authority to ensure that federal agencies and departments—including the United States Attorneys, the Federal Bureau of Investigation, the Drug Enforcement Administration, the Bureau of Alcohol, Tobacco, Firearms and Explosives, the United States Marshals Service, United States Immigration and Customs Enforcement, the Transportation Security Administration, U.S. Customs and Border Protection, the United States Coast Guard, the Office of National Drug Control Policy (ONDCP), the Puerto Rico/U.S. Virgin Islands High Intensity Drug Trafficking Area (a law enforcement program funded by ONDCP), the National Guard Bureau, the Deputy Assistant Secretary of Defense for Counternarcotics and Global Threats, U.S. Northern Command (whose area of responsibility includes Puerto Rico and the U.S. Virgin Islands), and U.S. Southern Command (whose area of responsibility includes the nations of South America, Central America, and the Caribbean, as well as the air and sea approaches to Puerto Rico from the south)—are working in coordination with each other, and with local law enforcement officials, to reduce drug trafficking and associated violence in Puerto Rico and the neighboring U.S. Virgin Islands.

The ONDCP, a component of the Executive Office of the President, prepares and publishes the annual National Drug Control Strategy, which outlines the Administration's efforts to reduce the supply of, and demand for, illegal drugs. ONDCP also prepares and publishes various reports that supplement the National Drug Control Strategy. The Office of National Drug Control Policy Reauthorization Act of 2006 (P.L. 109-469) requires ONDCP to prepare a National Southwest Border Counternarcotics Strategy, and ONDCP has published four such strategy documents. Likewise, the Northern Border Counternarcotics Strategy Act of 2010 (P.L. 111-356) requires ONDCP to prepare a Northern Border Counternarcotics Strategy, and ONDCP has

---

<sup>102</sup> These [annual homicide statistics](#) are from the Puerto Rico police, and—in certain cases—vary from statistics published by other sources.

<sup>103</sup> See Puerto Rico/U.S. Virgin Islands High Intensity Drug Trafficking Area, [Drug Market Analysis 2011](#), September 2011, at page 4.

published two such strategy documents. In [House Report 113-72](#), which accompanied [H.R. 2786](#), the Financial Services and General Government Appropriations Act, 2014, the House Appropriations Committee directed ONDCP “to develop a biennial Caribbean Border Counternarcotics Strategy, on terms equivalent to the existing Southwest Border Counternarcotics Strategy and the Northern Border Counternarcotics Strategy.” The joint explanatory statement accompanying H.R. 3547, the Consolidated Appropriations Act, 2014—enacted as [P.L. 113-76](#) on January 17, 2014—expressly adopted this directive, but modified the time given to ONDCP to prepare the Caribbean Border Counternarcotics Strategy from 90 days from the date of enactment to 120 days from the date of enactment. ONDCP [published](#) the Caribbean Border Counternarcotics Strategy on January 15, 2015. Assuming ONDCP adheres to the congressional directive to publish the Caribbean Border Counternarcotics Strategy on a biennial basis, an updated strategy document will be published in 2017.

The Task Force makes the following recommendations:

- The Task Force recommends that **Congress** enshrine in permanent law—as distinct from a committee report accompanying a single-year appropriations bill—the requirement that ONDCP prepare and publish a Caribbean Border Counternarcotics Strategy, just as Congress has enshrined in permanent law the requirement that ONDCP prepare a National Southwest Border Counternarcotics Strategy and a Northern Border Counternarcotics Strategy.
- Whether or not Congress does enshrine this requirement in permanent law, the Task Force recommends that **ONDCP** update the Caribbean Border Counternarcotics Strategy every two years, and ensure that the strategy document places particular emphasis on reducing drug supply, drug demand and drug-related violence in Puerto Rico and the U.S. Virgin Islands, the two U.S. jurisdictions in the Caribbean region.

For over a century, federal law has provided that the collection of certain duties, taxes and fees in Puerto Rico by U.S. Customs and Border Protection (CBP)—or its predecessor agencies—are to be deposited in what is often referred to as the Puerto Rico Trust Fund.<sup>104</sup> Pursuant to federal law and an implementing agreement between the federal government and the government of Puerto Rico, a significant portion of that revenue is used to fund certain federal operations in Puerto Rico, including the maritime operations of CBP’s Office of Air and Marine Operations. Because of a shortfall in the Puerto Rico Trust Fund due to reduced customs collections in Fiscal Year 2011, CBP closed a maritime unit in San Juan that, in prior years, had seized a significant quantity of illegal drugs. CBP took this action because it interpreted current federal law to require that it use either the Puerto Rico Trust Fund or the CBP Salaries and Expenses appropriation, but not both, in order to fund its operations in Puerto Rico. As a result, the Department of Homeland Security appropriations bill for Fiscal Year 2015 and Fiscal Year 2016

---

<sup>104</sup> See 48 U.S.C. 740 and 48 U.S.C. 795.

each include language authorizing CBP to supplement funding from the Trust Fund with general appropriations when necessary to maintain or to temporarily increase operations in Puerto Rico.

The Task Force makes the following recommendation:

- The Task Force recommends that **Congress** continue its current policy of providing CBP's Office of Air and Marine Operations with flexibility to use both the Puerto Rico Trust Fund and general appropriations to maintain or temporarily increase its operations in Puerto Rico.

## 11. Municipal Solid Waste Landfills

On October 14<sup>th</sup>, the Task Force held a staff-level briefing via phone with officials from the U.S. Environmental Protection Agency to discuss the subject of Puerto Rico's municipal solid waste landfills. Some members of the Task Force also met with representatives from Puerto Rico Limpio ("Clean Puerto Rico"), a Puerto Rico-based organization that has pursued an aggressive public campaign to raise awareness about the troubled state of Puerto Rico's landfills and about what Puerto Rico Limpio believes to be inadequate efforts on the part of EPA and the Puerto Rico Environmental Quality Board to address this matter. Although this issue falls somewhat outside of the Task Force's domain, the Task Force would be remiss if it did not discuss it briefly, given the risks to public health and the environment that appear to be posed by the status quo.

The Resource Conservation and Recovery Act of 1976 (RCRA) instituted the first federal permit program for hazardous waste management programs and prohibited open dumps. According to EPA's briefing to the Task Force and EPA's [website](#), there used to be approximately 70 landfills in Puerto Rico, many of which were "open dumps" and were closed post-RCRA. Currently, there are "approximately 29 operating landfills in Puerto Rico, the majority of which are beyond capacity." Most of these landfills are owned by the government of the municipality in which the landfill is located, and operated by the municipal government or a private company.

EPA notes that the Puerto Rico Environmental Quality Board (EQB) has had primary responsibility for regulating solid waste landfills on the island since 1994, when EPA approved EQB's solid waste compliance and enforcement program. Since 2007, EPA has reached [legal agreements](#) with 12 municipal governments to improve landfill operations and to place those landfills on a schedule for closure, and EPA indicates that it is "continuing to assess landfills throughout Puerto Rico and to develop legal agreements where appropriate." EPA reached these legal agreements pursuant to Section 7003 of RCRA, which authorizes EPA to take appropriate action if the handling or storage of solid waste "may present an imminent and substantial endangerment to health or the environment." According to a chart provided to the Task Force by EPA, about 70 percent of Puerto Rico's landfills are in violation of 40 CFR 258, EPA's

regulations governing solid waste management, including a number of landfills that EPA has not yet scheduled for closure.

Puerto Rico Limpio argues that EPA's efforts are insufficient, and that the agency should move more quickly to close non-compliant landfills and even rescind its 1994 approval of EQB's solid waste program. EPA responds that it is not practical to immediately close most landfills in Puerto Rico (particularly since proper closure requires significant funding, something the government of Puerto Rico and the island's municipal governments lack); that rescinding its approval of EQB's solid waste program would not improve the situation; and that the agency is doing the most it can in light of all of the factual and legal circumstances.

The Task Force makes the following recommendation:

- The Task Force is concerned with the state of Puerto Rico's municipal solid waste landfills, and the potential impact on public health and the environment. The Task Force recommends that the committees of jurisdiction in **Congress** examine this issue, which has only recently attracted significant public attention, to determine whether there are additional steps that can and should be taken.

## 12. Arecibo Observatory

The National Science Foundation (NSF) [owns](#) the Arecibo Observatory, a scientific research and education facility located on 118 acres of federal land in west-central Puerto Rico. The Department of Defense funded construction of the Observatory in the early 1960s to study the ionosphere. In 1969, the facility was [transferred](#) from DOD to NSF and converted to a national research center, with operations led by Cornell University. In 2011, the cooperative agreement between Cornell University and NSF expired. Following a competition, a new cooperative agreement was [awarded](#) by NSF to SRI International, with sub-awards made to Universities Space Research Association and the Universidad Metropolitana (UMET). Together, these entities form the Arecibo Management Team, which maintains and operates the Observatory on behalf of NSF. The cooperative agreement has a five-year term, ending in September 2016, although the parties have agreed to extend the agreement through March 31, 2018.

The Observatory is a leading research institution, enabling research in space and atmospheric sciences, radio astronomy and solar system radar studies. The iconic feature of the Observatory is a 305-meter-diameter spherical radio telescope, which has been used to make significant contributions to astronomy. The telescope is recognized as an engineering landmark and scientists from all over the world compete to utilize it and its supporting facilities. Currently, the Observatory serves scientific communities in various fields, while also hosting an active education and public outreach program. Observatory infrastructure includes office and

laboratory buildings, instrumentation for astronomy and physics, and lodging facilities for visiting scientists. The Observatory employs 128 people, including approximately 16 scientific staff, telescope operators, and support personnel. Many academic and research staff remotely access the Observatory to conduct research at their home institutions in the U.S. and abroad.

The Observatory has shared the results of its scientific investigations with the public since the opening of the Angel Ramos Foundation Science and Visitor Center in 1997. The visitor center provides science exhibits and a large auditorium, while the adjacent Angel Ramos Foundation Conference Center offers a classroom setting for workshops and professional meetings. The visitor center receives approximately 20,000 students per year and offers a variety of STEM-related opportunities for schoolchildren, teachers, and university students. As a result of the visitor center's role in making important research available to the public, it is included in the National Register of Historic Places (NRHP). Approximately 90,000 tourists visit the Arecibo Observatory annually, with local guided services and tour bus operators from San Juan providing day trips to the facility for a \$13 entrance fee. The Observatory attracts tourism to the Municipality of Arecibo, where the annual per capita income is less than \$10,000, and to the western part of Puerto Rico more generally.

The Observatory receives federal funding from NSF and the National Aeronautics and Space Administration (NASA). In Fiscal Year 2016, NSF provided \$8.2 million—with half provided by the NSF Division of Astronomical Sciences and half provided by the NSF Division of Atmospheric and Geospace Science—and NASA's Planetary Science Division provided \$3.7 million.

NSF has indicated that it needs to reduce funding for the Observatory, and has set forth possible alternative courses of action. On May 23, 2016, NSF published in the [Federal Register](#) a Notice of Intent to prepare an environmental impact statement.<sup>105</sup> On October 28<sup>th</sup>, NSF released its [Draft Environmental Impact Statement \(DEIS\)](#).

The DEIS analyzes [five](#) action alternatives, in addition to a no-action alternative. They are: (1) collaboration with interested parties for continued science-focused operations (NSF's preferred alternative); (2) collaboration with interested parties for transition to education-focused operations; (3) mothballing of facilities; (4) partial deconstruction and site restoration; and (5) complete deconstruction and site restoration.

As NSF acknowledges, reducing or ending operations at the Observatory would have numerous adverse socioeconomic effects in Arecibo and in Puerto Rico more generally, impacting job-creating economic activity currently generated by researchers, students and tourists. Moreover,

---

<sup>105</sup> See page 32349.

the Observatory is a unique STEM resource in a low-income U.S. jurisdiction that nonetheless manages to produce some of the top STEM professionals in the nation, and the Observatory's shuttering would come at a significant social and educational cost to the island.

The Task Force received two submissions regarding the Arecibo Observatory via the email portal. One is from the Angel Ramos Foundation, which emphasized the Center's STEM-related initiatives for students and researchers in Puerto Rico. The other is from the Universidad Metropolitana, which provided background on the Observatory and the Arecibo Management Team. Both submissions strongly opposed the decommissioning of the Observatory and recommended that operations be maintained or expanded instead.

The Task Force makes the following recommendation:

- The Task Force recognizes that the Arecibo Observatory is vital to Puerto Rico in a variety of ways, and believes that science-focused and education-focused operations should be continued at the site. The Task Force recommends that the **National Science Foundation**, in collaboration with other government and non-government stakeholders, take all feasible steps to achieve this result.

### 13. Former Naval Station Roosevelt Roads

The Naval Station Roosevelt Roads (NSRR), a large naval installation in northeastern Puerto Rico consisting of approximately 8,720 acres, closed on March 31, 2004 after supporting U.S. military operations for over 60 years.<sup>106</sup> The closure of a major military base can pose significant economic challenges to the surrounding communities, particularly in the short term, but it can also present substantial economic opportunities if the transition from military use to civilian use of the property is handled properly. A key role is played by the Local Redevelopment Authority (LRA)—an entity established by a state or local government, recognized by the Secretary of Defense through its [Office of Economic Adjustment](#), and responsible for preparing and implementing the redevelopment plan for the former base.

In 2004, the government of Puerto Rico enacted a law creating an [LRA](#) for Roosevelt Roads. According to a publically-available [source](#), the LRA consists of 11 staff members and has an annual budget of about \$3 million, of which 56 percent is from the government of Puerto Rico, 41 percent is from the federal government, and 3 percent is generated by the LRA itself.

---

<sup>106</sup> See [Report by the President's Task Force on Puerto Rico's Status](#), March 2011, at page 68-69; see also Naval Facilities Engineering Command, [Former Naval Station Roosevelt Roads](#).

According to the [LRA](#), the Department of Defense transferred 1,370 acres to the LRA in January 2012, and transferred 2,039 acres to the LRA in May 2013, for a total of 3,409 acres. The LRA has control of these lands and is able to execute redevelopment projects on nearly all of them. The transfer of lands from the Department of Defense to the LRA is now complete. (Of the remaining 5,000-plus acres of the former base, about 3,300 acres were transferred to the Puerto Rico Department of Natural and Environmental Resources and are being administered by the Puerto Rico Conservation Trust; the 1,600-acre airport was transferred to the Puerto Rico Ports Authority; a 140-acre beach was transferred to the municipality of Ceiba; 90 acres were transferred to other federal agencies; and a 30-acre hospital was transferred to the LRA.)

The redevelopment of NSRR has the potential to create many jobs and generate extensive economic activity in a geographic area of Puerto Rico that has high rates of unemployment and poverty. For example, the average 2015 [unemployment rate](#) in the municipality of Ceiba (population 12,000), where the NSRR is located, was 13.8 percent, while the unemployment rate in the neighboring municipalities of Naguabo (population 26,000) and Fajardo (population 33,000) was 13.3 percent and 14.8 percent, respectively.<sup>107</sup>

Recently, the federal government has taken steps to support the redevelopment of the NSRR. For example, in August 2015, the U.S. Small Business Administration (SBA) announced the [designation](#) of the NSRR as a Historically Underutilized Business Zone (HUBZone), which will enable small firms located within the former base to better compete for contracts to supply the federal government with goods and services. In addition, in June 2016 the federal government [designated](#) the NSRR as one of 22 “Promise Zones” throughout the United States. Promise Zones are federal-local partnerships in which economically-distressed areas receive priority access to federal investments and other forms of federal assistance.

Based on the foregoing, all of the pieces are in place for the former base to be redeveloped for the economic benefit of the people of Puerto Rico.

However, now that over 12 years have transpired since the base was closed and over three years have passed since the transfer of property from the Department of Defense to the LRA was completed, a candid assessment is in order. The effort to redevelop the former base has been slow. It has suffered from the same excessive degree of political interference that delays and disrupts far too many economic development projects in Puerto Rico. And it has been characterized by a redevelopment strategy that lacks coherence and consistency, shifting from one local administration to the next, and even from year to year within the same administration. To date, all of these efforts have resulted in the creation of [less than 50 jobs](#).

---

<sup>107</sup> See generally Tri-City Partnership (consisting of the mayors of Ceiba, Naguabo and Fajardo), Submission to Congressional Task Force on Economic Growth in Puerto Rico.

The Task Force makes the following recommendation:

- The Task Force is concerned by the slow pace of the effort to redevelop the former Naval Station Roosevelt Roads (NSRR) for the economic benefit of the people of Puerto Rico. The Task Force believes a well-planned and well-executed redevelopment strategy has the potential to transform eastern Puerto Rico. The Task Force recommends that the **government of Puerto Rico**, working in conjunction with the Revitalization Coordinator established in Section 502 of PROMESA, elected leaders of the surrounding communities, federal government partners, and the private sector, prioritize the efficient and effective redevelopment of the NSRR. The Task Force urges the Local Redevelopment Authority responsible for overseeing the redevelopment effort to develop a sensible and sustained strategy.

#### 14. Caño Martín Peña (Martín Peña Channel)

For approximately three decades, plans have been developed but not implemented to restore the Caño Martín Peña (Martín Peña Channel), a natural channel that connects the San Juan Bay with the San José Lagoon in metropolitan San Juan. The tidal flow between these two bodies of water and the flushing of the San José Lagoon has been impeded by persistent sedimentation and debris accumulation in the Caño. Many of the communities along the Caño lack sewer systems. Health studies have determined that frequent flooding in these communities is associated with high rates of gastrointestinal disease, asthma, and skin rashes among residents, particularly children. Habitat for fish and wildlife has also been lost due to water quality degradation.

Through the Water Resources Development Act of 2007 (WRDA), Congress provided a process for authorizing the restoration of Caño Martín Peña as a U.S. Army Corps of Engineers civil works project. On May 18, 2016, the Assistant Secretary of the Army for Civil Works signed a record of decision approving the [final feasibility report and environmental impact statement](#) for this project. The plan generally calls for the Corps of Engineers to dredge approximately 2.2 miles of the eastern half of the Caño to a width of 100 feet and a depth of 10 feet. The walls of the dredged Caño are to be constructed with concrete and steel. The project, once completed, will restore the natural tidal connection between the San Juan Bay and the San José Lagoon. Residents of the eight communities along the Caño would benefit from a healthy waterway, revitalized neighborhoods, and greater economic opportunities. Their homes and critical infrastructure in the area—including the runway for the San Juan International Airport adjacent to the San José Lagoon—would face reduced flood risks.

Obstacles to project construction, which is estimated to cost a total of \$222 million, include the lack of an appropriation from Congress for the project; the limited ability of the non-federal

sponsor ENLACE, an entity of the government of Puerto Rico, to satisfy its cost sharing obligations; and legal considerations related to the relocation of households located in the project area.

The Task Force makes the following recommendation:

- The Task Force believes that the project to restore Caño Martín Peña can provide a significant return on investment for the federal government in terms of improving the economy, protecting public health, and restoring the natural environment in some of Puerto Rico’s most distressed communities. The Task Force recommends that the **U.S. Army Corps of Engineers** and the **non-federal sponsor ENLACE** finalize the Project Partnership Agreement (PPA) for the project as soon as feasible; that **Congress** consider appropriating funding to construct this project; and that **Congress** consider relaxing the cost-sharing obligations of the non-federal sponsor or otherwise taking steps to ensure that the government of Puerto Rico’s fiscal crisis does not result in forward progress on this project being halted.

## 15. Federal Interagency Advisory Council on Child Poverty

The Task Force notes a proposal made to the Task Force by the Boys and Girls Clubs of Puerto Rico and the Youth Development Institute (*Instituto de Desarrollo de la Juventud*) to temporarily establish a “Federal Interagency Advisory Council on Child Poverty,” consisting of experts from inside and outside of government, that would examine and report to Congress on steps that can be taken at the federal level to reduce child poverty, with a particular emphasis on those U.S. jurisdictions—like Puerto Rico, where nearly 64 percent of young children live below the federal poverty level—that have persistently high rates of child poverty. Under this proposal, a principal goal of the Council would be to help craft an overarching strategic framework to address multi-generational poverty. The Task Force wishes to express its appreciation to the dedicated representatives of the Boys and Girls Clubs of Puerto Rico, who took the time to arrange for Task Force staff visiting the island to meet with families residing in government-provided housing in Puerto Rico, with unemployed and underemployed individuals seeking employment, and with other community members. Individuals who are fourth-generation public housing residents underscore the need for efforts to improve economic opportunities in Puerto Rico and to address enduring child poverty on the island.

The Task Force makes the following recommendation:

- The Task Force recommends that the **federal government** consider establishing, either through congressional or executive action, a “Federal Interagency Advisory Council on Child

Poverty” or a functionally equivalent entity, which would examine and report to Congress on ways to address persistent child poverty in the United States, including its territories.

## **16. Unemployment Compensation Demonstration Project**

The Unemployment Compensation (UC) program provides income support to eligible workers through the payment of UC benefits during a period of unemployment. The UC system operates in each state, the District of Columbia, Puerto Rico, and the U.S. Virgin Islands. Puerto Rico is considered a state under UC law. The UC program is financed by federal taxes under the Federal Unemployment Tax Act (FUTA) and by state payroll taxes under the State Unemployment Tax Acts (SUTA). These taxes are deposited in the appropriate accounts within the Unemployment Trust Fund (UTF). Most businesses in the United States, including those in Puerto Rico, are subject to both state and federal unemployment taxes. An estimated \$5.8 billion in federal unemployment taxes and \$40.9 billion in state unemployment taxes were collected in Fiscal Year 2016.

UC benefits are available for up to 26 weeks in most states, including Puerto Rico. These benefits are mostly paid for by the state out of state unemployment taxes. The federal government pays certain administrative costs only.

Federal law prescribes how a state may use its state unemployment taxes, generally requiring a state to utilize those taxes only to pay unemployment benefits. However, as part of a bipartisan compromise to extend federal unemployment insurance, Section 2102 of the [Middle Class Tax Relief and Job Creation Act of 2012](#) (P.L. 112-96) authorized states to use the revenues from their SUTA taxes for certain purposes other than paying benefits. Specifically, Section 2102 authorized the U.S. Department of Labor to allow up to 10 states, including Puerto Rico, to conduct demonstration projects to improve and accelerate the reemployment of UC claimants. Pursuant to these demonstration projects, states could provide subsidies for employer-provided training, such as wage subsidies, or provide direct disbursements, not to exceed the weekly benefit amount of an individual, to employers who hire individuals receiving UC to pay part of the cost of wages that exceed the individual’s prior benefit level. No demonstration project could be approved for more than three years and all projects were required to end by December 31, 2015.

It is generally agreed that Section 2102, and the April 2012 [guidance](#) that DOL issued to states regarding its implementation of that section, proved cumbersome and ultimately unworkable. Only one state submitted an application, no state demonstration project was approved by DOL, and the program has now expired. In 2014, legislation was introduced in the

U.S. House of Representatives to make various modifications to Section 2012 and to extend the demonstration project authority from December 31, 2015 to December 31, 2019.<sup>108</sup>

Proponents of allowing states to use UC benefits to subsidize employment assert that such initiatives can help unemployed workers receive job training and expedite reentry into the workforce. Critics raise concerns over the “quality” of jobs in which participants are often placed and point to the low percentage of participants retained after the subsidy ends.<sup>109</sup>

The Task Force makes the following recommendation:

- Given that Puerto Rico has a higher unemployment rate and lower labor force participation rate than any state, the Task Force recommends that **Congress** consider the merits and demerits of legislation to authorize Puerto Rico to have greater flexibility in its use of Unemployment Compensation benefits for the purpose of increasing employment.

## 17. Administrative Order 346

Section 409(g)(3) of PROMESA requires the Task Force to examine the “economic effect” of Administrative Order 346, issued by the Secretary of the Puerto Rico Department of Health on February 9, 2016.<sup>110</sup>

The Order required manufacturers and distributors of “natural products” and “dietary supplements” to register with, and pay certain fees to, the government of Puerto Rico. The Puerto Rico Secretary of Health characterized the Order as an effort to ensure the quality of products sold in Puerto Rico and to protect consumer health on the island. Affected manufacturers and distributors asserted that the Order constituted administrative overreach, suffered from substantive and procedural defects, and was intended primarily to raise revenue for the government, rather than to protect public health.

On September 21, 2016, the Task Force received a letter from the Puerto Rico Secretary of Health. The letter indicated that the Department of Health would issue an administrative order to place a 120-day “moratorium” on Administrative Order 346, draft a “new regulation” to replace

---

<sup>108</sup> See H.R. 2509, Flexibility to Promote Reemployment Act (114<sup>th</sup> Congress; Rep. Renacci).

<sup>109</sup> See Julie M. Whittaker, “Expediting the Return to Work: Approaches in the Unemployment Compensation Program,” Congressional Research Service, May 1, 2013.

<sup>110</sup> For the English-language text of the Order, see National Products Association, Submission #1 to Congressional Task Force on Economic Growth in Puerto Rico. For the Spanish-language text of the Order, see Council for Responsible Nutrition, Submission to Congressional Task Force on Economic Growth in Puerto Rico, Attachment #1.

the Order that complied with Puerto Rico law, and hold “public hearings” so that all affected parties could provide their “comments and recommendations.”

On September 26<sup>th</sup>, Task Force staff held a phone conversation with the Secretary of Health and her advisors to discuss this subject.

The Task Force makes the following recommendation:

- If the Puerto Rico Department of Health does choose to replace Administrative Order 346 with a new regulation, the Task Force recommends to the **Puerto Rico Department of Health** that it follow through on the Secretary’s pledge to hold public hearings on the proposed regulation so that all stakeholders, whether they support or oppose administrative action, can provide comments. If a new regulation is approved, and if any affected party believes the regulation violates Puerto Rico or federal law, the Task Force notes that the affected party may avail itself of the local or federal courts in Puerto Rico, just as it could in any other U.S. jurisdiction.

## 18. Puerto Rico’s Political Status

Puerto Rico—along with American Samoa, Guam, the Northern Mariana Islands and the U.S. Virgin Islands—is an unincorporated territory of the United States. As a territory, Puerto Rico is subject to Congress’s plenary powers under the Territory Clause of the United States Constitution.<sup>111</sup> The U.S. Supreme Court has held that, so long as Congress does not abridge the fundamental rights of individuals living in the territories, Congress can enact laws that treat the territories differently than the states if there is any rational basis for the differential treatment. Puerto Rico and the other territories are treated differently than the states under a variety of federal programs.

Each of the five U.S. territories elects a single delegate to the U.S. House of Representatives, who (under current House rules approved by the membership of the House) can introduce legislation, serve on House committees, and vote on legislation at the committee stage. However, the territorial delegates cannot vote on legislation on the floor of the House. The territories do not elect U.S. senators. The territories can—and, currently, each of the five territories does—participate in presidential primaries, but the territories cannot participate in the general election for president.

---

<sup>111</sup> See U.S. Constitution, Article IV, Section 3, Clause 2 (granting Congress the “Power to dispose of and make all needful Rules and Regulations respecting the Territory or other Property belonging to the United States”).

The term “unincorporated” territory denotes that Puerto Rico retains the potential—legally speaking—to: become a state of the United States; become a sovereign nation, either fully independent from the United States or with a voluntary compact of free association with the United States; or maintain its current status.

As a practical matter, in order for Puerto Rico to change its political status, the people of Puerto Rico—through an exercise of their right to self-determination—must first request a change in status in a fair and impartial plebiscite. If the people of Puerto Rico do request a change in status, the federal government would have to enact legislation to approve the requested change.

Puerto Rico has held four plebiscites on the territory’s political status, each of which was conducted pursuant to Puerto Rico law. These plebiscites were held in 1967, 1993, 1998, and 2012.

In January 2014, Congress enacted the [Consolidated Appropriations Act, 2014](#) (P.L. 113-76). The law includes an appropriation of \$2.5 million to the State Elections Commission of Puerto Rico to be used for “objective, nonpartisan voter education about, and a plebiscite on, options that would resolve Puerto Rico’s future political status.”<sup>112</sup> The House Committee on Appropriations’ report explains this appropriation as follows:

“Puerto Rico plebiscite.—The recommendation includes \$2,500,000 for objective, nonpartisan voter education about, and a plebiscite on, options that would resolve Puerto Rico’s future political status. The funds provided for the plebiscite shall not be obligated until 45 days after the [United States] Department [of Justice] notifies the Committees on Appropriations that it approves of an expenditure plan from the Puerto Rico State Elections Commission for voter education and plebiscite administration, including approval of the plebiscite ballot. This notification shall include a finding that the voter education materials, plebiscite ballot, and related materials are not incompatible with the Constitution and laws and policies of the United States.”<sup>113</sup>

Section 402 of PROMESA states: “Nothing in this Act shall be interpreted to restrict Puerto Rico’s right to determine its future political status, including by conducting the plebiscite as authorized by Public Law 113–76.”

The Task Force makes the following recommendation:

---

<sup>112</sup> See [Consolidated Appropriations Act, 2014](#), at page 57.

<sup>113</sup> See [House Report 113-171](#), at page 53.

- If the government of Puerto Rico conducts a plebiscite authorized and funded by Public Law 113-76, the Task Force recommends that **Congress** analyze the result of this plebiscite with care and seriousness of purpose, and take any appropriate legislative action.

**Appendix 2: Federal Programs Under Which Puerto Rico Receives Differential Treatment**

<b>Federal Programs Under Which Puerto Rico Receives Differential Treatment</b>			
<b>Program</b>	<b>Federal Agency that Administers Program</b>	<b>Congressional Committees With Jurisdiction Over Program (114th Congress)</b>	<b>Description of Differential Treatment</b>
Supplemental Nutrition Assistance Program (SNAP)/Nutrition Assistance Program (NAP)	U.S. Department of Agriculture (USDA), Food and Nutrition Service (FNS)	House Committee on Agriculture  Senate Committee on Agriculture, Nutrition and Forestry	SNAP is designed to increase the food purchasing power of eligible low-income households so they can buy a nutritionally adequate diet. The states, DC, Guam and the U.S. Virgin Islands participate in SNAP. Maximum monthly benefit allotments are tied to the cost of purchasing a nutritionally adequate low-cost diet, as measured by the USDA-created and USDA-calculated Thrifty Food Plan (TFP). Maximum allotments are standard across the 48 contiguous states and DC, but are higher in Alaska, Hawaii, Guam, and the U.S. Virgin Islands. Puerto Rico, the CNMI and American Samoa do not participate in SNAP, although the 2014 Farm Bill authorized a pilot program that may result in the CNMI's inclusion in SNAP. Effective in 1982, Congress ended Puerto Rico's participation in SNAP (then, the Food Stamp Program), which is an open-ended entitlement, and provided a nutrition assistance block grant, known as the Nutrition Assistance Program (NAP). The NAP block grant is adjusted annually for inflation as measured by the change in the cost of the contiguous states' TFP. In Fiscal Year 2016, the NAP block grant was \$1.959 billion. According to a June 2010 FNS report required by Congress, based on Fiscal Year 2009 funding levels, converting Puerto Rico from NAP to SNAP would increase the number of households that receive nutrition assistance by 15.3 percent, increase the average monthly benefit per household by 9.6 percent, and increase annual spending on benefits by \$420 million.
Supplemental Nutrition Assistance Program Education (SNAP-Ed)	U.S. Department of Agriculture (USDA), Food and Nutrition Service (FNS)	House Committee on Agriculture  Senate Committee on Agriculture, Nutrition and Forestry	A goal of SNAP-Ed is to improve the likelihood that persons eligible for SNAP will make healthy choices within a limited budget. The Healthy, Hunger-Free Kids Act of 2010 (P.L. 111-296) redesigned this program's funding, transitioning from (1) an open-ended funding stream for SNAP "state agencies" that put up matching funds to (2) a formula grant that provides an allocation for all SNAP "state agencies." The authorizing statute allocates formula funding to "state agencies" and, under 7 U.S.C. 2012(r)-(s), Guam and the U.S. Virgin Islands (who participate in SNAP) are "state agencies," but Puerto Rico, the CNMI and American Samoa are not. In Fiscal Year 2017, FNS will apportion \$414 million in SNAP-Ed funding to the states, DC, Guam, and the U.S. Virgin Islands. In Fiscal Year 2015, Puerto Rico used \$516,000 of its NAP block grant for its Nutrition Education Program.
Title I-A: (1) Basic Grants, (2) Concentration Grants, (3) Targeted Grants, and (4) Education Finance Incentive	U.S. Department of Education (USDE)	House Committee on Education and the Workforce  Senate Committee on Health,	Title I-A authorizes aid to local educational agencies (LEAs) for the education of disadvantaged children. Funds are allocated to LEAs via states using four different allocation formulas specified in statute: (1) Basic Grants, (2) Concentration Grants, (3) Targeted Grants, and (4) Education Finance Incentive Grants. Under each of the four formulas, Puerto Rico is treated as a state

Grants		Education, Labor and Pensions	for determining grant amounts. However, there are special caps that apply to the amount of funding that Puerto Rico is able to receive. CRS has estimated that Puerto Rico's Fiscal Year 2016 Title I-A grants would be \$51.9 million (12.7 percent) higher in the absence of these caps, increasing from \$408 million to \$460 million.
Title I-C: Migrant Education Programs	U.S. Department of Education (USDE)	House Committee on Education and the Workforce  Senate Committee on Health, Education, Labor and Pensions	Title I-C authorizes grants to state educational agencies (SEAs) for the education of migratory students. Funds are allocated by formula on the basis of each state's number of migratory students aged 3-21 and average per pupil expenditure (APPE) in the state. The allocation for Puerto Rico is based on the number of migratory children and a reduced APPE. Because Puerto Rico terminated its participation in the program in Fiscal Year 2006, CRS was unable to estimate how much funding for Puerto Rico might increase if a reduced APPE were not used.
Title I-D: Neglected, Delinquent and At-Risk Students Programs	U.S. Department of Education (USDE)	House Committee on Education and the Workforce  Senate Committee on Health, Education, Labor and Pensions	Title I-D authorizes a pair of programs intended to improve education for students who are neglected, delinquent, or at risk of dropping out of school. The funds appropriated for Title I-D are used to provide state grants. Under this formula, Puerto Rico is treated as a state with one exception related to the expenditure factor used to determine Puerto Rico's grant amount. CRS has estimated that Puerto Rico's Fiscal Year 2016 Title I-D grant of \$1.0 million would be \$828,000 in the absence of this exception, which is \$174,000 lower.
Title III-A: English Language Acquisition Grants	U.S. Department of Education (USDE)	House Committee on Education and the Workforce  Senate Committee on Health, Education, Labor and Pensions	Title III-A is designed to help ensure that English learners (ELs) and immigrant students attain English proficiency. Formula grant allocations are made to states based on the proportion of ELs and immigrant students in each state relative to all states. Grants to Puerto Rico are capped at 0.5 percent of the total amount available for state grants. USDE estimated Puerto Rico's Fiscal Year 2016 Title III-A grant to be \$3.4 million. CRS calculated that, if the cap were increased from 0.5 percent to 2.0 percent (rather than eliminated altogether), Puerto Rico's Title III-A grant would increase by \$10.2 million, to \$13.6 million.
Title IV-A: Student Support and Academic Enrichment Grants	U.S. Department of Education (USDE)	House Committee on Education and the Workforce  Senate Committee on Health, Education, Labor and Pensions	Title IV-A of the Every Student Succeeds Act (ESSA) authorizes Student Support and Academic Enrichment Grants to provide students with access to a well-rounded education, improve school conditions for student learning, and improve the use of technology. Funds are allocated via formula to state educational agencies (SEAs) based on their Title I-A grant amounts. The minimum state grant amount is 0.5 percent of the amount available to states. Puerto Rico's grant is capped at the minimum state grant amount. The block grant is authorized at \$1.65 billion for Fiscal Year 2017. CRS used a funding level of \$1.0 billion (the amount approved by the House Appropriations Committee) to estimate Fiscal Year 2017 grant amounts, and calculated that Puerto Rico's grant would be \$4.9 million with the cap and \$24.9 million without the cap, an increase of \$20.1 million.

Title IV-B: 21st-Century Community Learning Centers	U.S. Department of Education (USDE)	House Committee on Education and the Workforce  Senate Committee on Health, Education, Labor and Pensions	The 21st Century Community Learning Centers program supports activities during non-school hours that offer academic enrichment and additional services, such as counseling and nutrition and health education, for school-aged children. Funds may also be used to support expanded learning programs. Formula grant allocations are made to states in proportion to their Title I-A grant amounts. Because Puerto Rico’s Title I-A grant amount is affected by special caps and other provisions that have the effect of reducing the grant amount Puerto Rico would otherwise receive, the amount of funding Puerto Rico receives under the 21st Century Community Learning Centers is less than the amount Puerto Rico would receive if its Title I-A grant amount was not reduced by special provisions. CRS has estimated that Puerto Rico’s Fiscal Year 2016 Title IV-B grants would be \$4.1 million (14.1 percent) higher in the absence of these caps, increasing from \$29.4 million to \$33.5 million.
Title V-B: Rural Education Achievement Program	U.S. Department of Education (USDE)	House Committee on Education and the Workforce  Senate Committee on Health, Education, Labor and Pensions	Like Hawaii and DC, Puerto Rico is a “single LEA state”—meaning that the entire territory is considered one LEA. To be eligible for funds under Title V-B, the locale code for each school in an LEA must be classified as rural according to the National Center for Education Statistics (NCES) classification system. Since multiple schools in Puerto Rico are classified as non-rural, the territory is not eligible to receive Title V-B funds.
Title V-B: Rural and Low-Income School Program (Rural and Low-Income School Grant Program; RLIS)	U.S. Department of Education (USDE)	House Committee on Education and the Workforce  Senate Committee on Health, Education, Labor and Pensions	Like Hawaii and DC, Puerto Rico is a “single LEA state”—meaning that the entire territory is considered one LEA. To be eligible for funds under Title V-B, the locale code for each school in an LEA must be classified as rural according to the National Center for Education Statistics (NCES) classification system. Since multiple schools in Puerto Rico are classified as non-rural, the territory is not eligible to receive Title V-B funds.
Education for Homeless Children and Youths—Grants for State and Local Activities	U.S. Department of Education (USDE)	House Committee on Education and the Workforce  Senate Committee on Health, Education, Labor and Pensions	The Education for Homeless Children and Youths (EHCY) program authorized under the McKinney-Vento Homeless Assistance Act provides assistance to SEAs and LEAs to ensure that all homeless children and youth have equal access to the same free, appropriate public education that is provided to other children and youth. Formula grant allocations are made to states in proportion to their Title I-A grant amounts with no hold harmless provisions applied. As Puerto Rico’s Title I-A grant amount is affected by special caps and other provisions which have the effect of reducing the grant amount Puerto Rico would otherwise receive, the amount of funding Puerto Rico receives under the Homeless Education program is less than the amount Puerto Rico would receive if its Title I-A grant amount was not reduced by the Title I-A special provisions. CRS used a funding level of \$70 million to estimate Fiscal Year 2016 grant amounts, and calculated that Puerto Rico’s grant would be \$263,000 (14.6 percent) higher in the absence of these caps, increasing from \$1.8 million to approximately \$2.1 million.
TRICARE	U.S. Department of Defense (DOD)	House Committee on Armed Services  Senate Committee on Armed Services	TRICARE is the health care program of the U.S. Department of Defense Military Health System. TRICARE has four main benefit plans: a fee-for-service option (TRICARE Standard), a health maintenance organization option (TRICARE Prime), a preferred provider option (TRICARE Extra), and a Medicare wrap-around

			<p>option for Medicare-eligible military retirees (TRICARE for Life). Military retirees are veterans who served on active duty for at least 20 years or were medically retired. Under current law, military retirees in the territories are eligible for TRICARE Standard, but not TRICARE Prime. This is because the territories are considered “overseas” locations for purposes of military health care services, and are therefore treated as the functional equivalent of foreign countries. In the states, access to TRICARE Prime is available to retirees who reside in “Prime Service Areas,” or PSAs. According to a 2015 Department of Defense report to Congress, there are PSAs in 46 of the 50 states (the exceptions being Iowa, Minnesota, Vermont, and Wisconsin) and DC. There are over 635,000 military retirees enrolled in TRICARE Prime nationwide, and approximately one million family members of retirees enrolled in TRICARE Prime, who also receive coverage under Prime. The Department of Defense has the authority under current law to extend TRICARE Prime to some or all of the territories.</p>
Supplemental Security Income (SSI)/Aid to the Aged, Blind, or Disabled (AABD)	<p>SSI: Social Security Administration (SSA)</p> <p>AABD: U.S. Department of Health and Human Services (HHS), Administration for Children and Families (ACF)</p>	<p>House Committee on Ways and Means</p> <p>Senate Committee on Finance</p>	<p>SSI, administered by the SSA, provides monthly cash benefits to low-income aged, blind, or disabled persons in the 50 states, DC, and the Northern Mariana Islands. In 2016, the maximum monthly SSI payment is \$733 for an individual and \$1,100 for a couple if both members are eligible for SSI. In August 2016, the average monthly SSI payment was \$540 for all recipients, \$645 for children, \$561 for working-age adults, and \$435 for seniors. Congress has not extended the SSI program to Puerto Rico, which instead participates in AABD, administered by ACF within HHS. While SSI provides monthly benefits directly to eligible individuals, the federal government provides AABD funding to the Puerto Rico government, which distributes it to eligible individuals. The Puerto Rico government must provide certain local matching funds. Based on a 2014 GAO report, and on information supplied to the Task Force by ACF, the federal government provides approximately \$24 to \$26 million annually to the Puerto Rico government, which is used to provide benefits to approximately 34,000 to 38,000 individuals, who receive an average monthly benefit of approximately \$74 to \$77 per recipient. The GAO calculated that, if Puerto Rico were included in SSI in Fiscal Year 2011, Puerto Rico beneficiaries would receive between \$1.5 billion and \$1.8 billion per year, 305,000 to 354,000 individuals would receive benefits, and the average monthly benefit would be around \$540. The Puerto Rico government would have no matching requirement for benefit payments or administrative costs.</p> <p><b>NOTE REGARDING SOCIAL SERVICES FUNDING CAP:</b> Puerto Rico is subject to an overall annual federal funding cap of \$107,255,000 set forth in Section 1108 of the Social Security Act. The four federal programs subject to the Section 1108 cap are (1) <i>the AABD program</i>, (2) the Temporary Assistance for Needy Families (TANF) program, (3) various child welfare funding streams under Title IV-E of the Social Security Act, and (4) the Matching Grants to the territories under Section 1108(b) of the Social Security Act.</p>

Temporary Assistance for Needy Families (TANF, Title IV-A of the Social Security Act)	U.S. Department of Health and Human Services (HHS), Administration for Children and Families (ACF)	House Committee on Ways and Means  Senate Committee on Finance	<p>The TANF block grant provides federal grants to the states and territories for a wide range of benefits, services, and activities, including helping states and territories pay for cash welfare for needy families with children. TANF generally applies to Puerto Rico and the other territories in the same manner as it applies to the states and DC, in terms of its purpose, flexibility to use federal grants, program requirements, and the computation of the TANF basic block grant (which, in Puerto Rico, is set at \$71.6 million). TANF’s application to Puerto Rico and the other territories differs in that they are ineligible for certain TANF grants—supplemental grants (not currently applicable), contingency funds, and mandatory child care funds—that certain qualifying states may receive. On the other hand, Puerto Rico and the other territories may receive special matching funds for TANF, child care, and Title IV-E foster care and permanency programs under Section 1108(b) of the Social Security Act.</p> <p>NOTE REGARDING SOCIAL SERVICES FUNDING CAP: Puerto Rico is subject to an overall annual federal funding cap of \$107,255,000 set forth in Section 1108 of the Social Security Act. The four federal programs subject to the Section 1108 cap are (1) the AABD program, (2) <i>the Temporary Assistance for Needy Families (TANF) program</i>, (3) various child welfare funding streams under Title IV-E of the Social Security Act, and (4) the Matching Grants to the territories under Section 1108(b) of the Social Security Act.</p>
Temporary Assistance for Needy Families (TANF) Contingency Fund (Title IV-A of the Social Security Act)	U.S. Department of Health and Human Services (HHS), Administration for Children and Families (ACF)	House Committee on Ways and Means  Senate Committee on Finance	Only the 50 states and DC are eligible to receive funding under the TANF Contingency Fund; Puerto Rico and the other territories are not eligible. See 42 U.S.C. 603(b)(7). States qualify based on high unemployment, Supplemental Nutrition Assistance Program (SNAP) caseloads, and state expenditures above what was spent in Fiscal Year 1994.
Child Care Mandatory and Matching Funds of the Child Care and Development Fund (Title IV-A of the Social Security Act)	U.S. Department of Health and Human Services (HHS), Administration for Children and Families (ACF)	House Committee on Ways and Means  Senate Committee on Finance	Only the 50 states and DC are eligible to receive funding under the Child Care Mandatory and Matching Funds program; Puerto Rico and the other territories are not eligible. See 42 U.S.C. 618(d). There are two different mandatory child care funding streams: (1) “guaranteed” mandatory funds, and (2) mandatory matching funds. Guaranteed mandatory funds are allocated to states based on the amount each state received for certain welfare-related child care programs in Fiscal Year 1994 or Fiscal Year 1995, or the average of Fiscal Year 1992-Fiscal Year 1994, whichever is greater. Mandatory matching funds are distributed to states based on their relative share of children under age 13. To receive their full share of mandatory matching funds, states must meet maintenance-of-effort and matching requirements.
Title IV-E Foster Care, Adoption Assistance, Guardianship Assistance Program (Title IV-E of the Social Security Act)	U.S. Department of Health and Human Services (HHS), Administration for Children and Families (ACF)	House Committee on Ways and Means  Senate Committee on Finance	Title IV-E of the Social Security Act entitles states and territories with an approved Title IV-E plan to reimbursement of part of their costs of providing foster care, adoption assistance, and kinship guardianship assistance on behalf of eligible children. Puerto Rico is the only territory with an approved Title IV-E plan. Federal Title IV-E support is offered on an open-ended basis to states, but is subject to the social services spending cap in Puerto Rico. The share of federal Title IV-E support provided is 50 percent for program administration costs; 75 percent for program training

			<p>costs; and the state or territory's Federal Medical Assistance Percentage (FMAP) for foster care maintenance, adoption assistance, and guardianship assistance payments. State FMAPs are recalculated annually and may vary from 50 percent to 83 percent; states with the highest per capita income relative to the nation receive lower federal support and vice versa. Puerto Rico's FMAP (as applied to Title IV-E) is fixed at 55 percent. For Fiscal Year 2015, Puerto Rico submitted federal Title IV-E foster care and adoption assistance claims of about \$5.4 million, primarily for foster care, and received federal reimbursement of \$2.8 million. Puerto Rico has not opted to provide Title IV-E guardianship assistance.</p> <p>Federal eligibility rules for Title IV-E foster care include state/territory-specific income limits, tied to program rules in the now-defunct Aid to Families with Dependent Children (AFDC) program, as they existed in July 1996. A federal review of Puerto Rico's Title IV-E claims in 2003 indicated that the territory did not have procedures to properly limit Title IV-E claims to children meeting these IV-E foster care eligibility criteria. Puerto Rico's Title IV-E claims subsequently dropped to nearly zero. While Puerto Rico made corrections to its claiming system, for Fiscal Year 2015 it indicated that IV-E foster care maintenance payments were provided to just 252 children on an average monthly basis.</p> <p>NOTE REGARDING SOCIAL SERVICES FUNDING CAP: Puerto Rico is subject to an overall annual federal funding cap of \$107,255,000 set forth in Section 1108 of the Social Security Act. The four federal programs subject to the Section 1108 cap are (1) the AABD program, (2) the Temporary Assistance for Needy Families (TANF) program, (3) <i>various child welfare funding streams under Title IV-E of the Social Security Act</i>, and (4) the Matching Grants to the territories under Section 1108(b) of the Social Security Act.</p>
<p>Chafee Foster Care Independence Program, including Educational and Training Vouchers (Section 477 of the Social Security Act)</p>	<p>U.S. Department of Health and Human Services (HHS), Administration for Children and Families (ACF)</p>	<p>House Committee on Ways and Means</p> <p>Senate Committee on Finance</p>	<p>The John H. Chafee Foster Care Independence Program (CFCIP) authorizes funding for states and territories to provide services to help youth make a successful transition from foster care to adulthood. Funding for this program is authorized as a capped entitlement to states and territories provided they have an approved Title IV-E foster care and adoption assistance plan. Annual mandatory funding is authorized at \$140 million and is distributed by formula; the federal share of program costs is 80 percent. Funding for Chafee Educational and Training Vouchers (ETVs) is available to states and territories receiving Chafee grants and may be used to provide vouchers (valued at up to \$5,000 per year) to support post-secondary education and training for youth who have aged out (or are expected to age out) of foster care. Annual funding is authorized on a discretionary basis and is distributed by formula to each state or territory that receives CFCIP funds; the federal share of program costs is 80 percent. For Fiscal Year 2015, Congress provided just over \$43 million for the ETV program. Puerto Rico is the only territory with a Title IV-E plan and thus the only one receiving CFCIP and ETV funds. For Fiscal Year 2015, Puerto Rico's CFCIP allotment was \$1,376,075 and its ETV allotment was \$444,652.</p>

			<p>NOTE REGARDING SOCIAL SERVICES FUNDING CAP: Puerto Rico is subject to an overall annual federal funding cap of \$107,255,000 set forth in Section 1108 of the Social Security Act. The four federal programs subject to the Section 1108 cap are (1) the AABD program, (2) the Temporary Assistance for Needy Families (TANF) program, (3) <i>various child welfare funding streams under Title IV-E of the Social Security Act</i>, and (4) the Matching Grants to the territories under Section 1108(b) of the Social Security Act.</p>
Adoption and Legal Guardianship Incentive Payments (Section 473A of the Social Security Act)	U.S. Department of Health and Human Services (HHS), Administration for Children and Families (ACF)	House Committee on Ways and Means  Senate Committee on Finance	<p>Adoption and Legal Guardianship Incentive Payments are awarded to states and territories (with a Title IV-E plan) that increase the rate at which children who cannot return home leave foster care to permanent adoptive families or legal guardians. Funding for incentive payments is authorized on a discretionary basis and awarded to states and territories based on their performance. For Fiscal Year 2016, Congress provided \$38 million for these incentive payments. Puerto Rico is the only territory with a Title IV-E plan and thus the only one eligible for these incentive payments. For adoptions and legal guardianships finalized in Fiscal Year 2014, the most recent data publicly available, Puerto Rico received an incentive payment of \$5,000.</p> <p>NOTE REGARDING SOCIAL SERVICES FUNDING CAP: Puerto Rico is subject to an overall annual federal funding cap of \$107,255,000 set forth in Section 1108 of the Social Security Act. The four federal programs subject to the Section 1108 cap are (1) the AABD program, (2) the Temporary Assistance for Needy Families (TANF) program, (3) <i>various child welfare funding streams under Title IV-E of the Social Security Act</i>, and (4) the Matching Grants to the territories under Section 1108(b) of the Social Security Act.</p>
Section 1108(b) Matching Grants to the Territories (Section 1108(b) of the Social Security Act)	U.S. Department of Health and Human Services (HHS), Administration for Children and Families (ACF)	House Committee on Ways and Means  Senate Committee on Finance	<p>Puerto Rico and the other territories qualify for Section 1108(b) Matching Grants based on having territorial government expenditures in excess of what the territory in question spent in Fiscal Year 1995. Section 1108(b) Matching Grants may be used for TANF, including child care, or Title IV-E foster care and permanency programs. Section 1108(b) Matching Grants include a 25 percent territory government matching requirement.</p> <p>NOTE REGARDING SOCIAL SERVICES FUNDING CAP: Puerto Rico is subject to an overall annual federal funding cap of \$107,255,000 set forth in Section 1108 of the Social Security Act. The four federal programs subject to the Section 1108 cap are (1) the AABD program, (2) the Temporary Assistance for Needy Families (TANF) program, (3) <i>various child welfare funding streams under Title IV-E of the Social Security Act</i>, and (4) <i>the Matching Grants to the territories under Section 1108(b) of the Social Security Act</i>.</p>

<p>Low-Income Home Energy Assistance Program (LIHEAP)</p>	<p>U.S. Department of Health and Human Services (HHS), Administration for Children and Families (ACF)</p>	<p>House Committee on Energy and Commerce; House Committee on Education and the Workforce</p> <p>Senate Committee on Health, Education, Labor and Pensions</p>	<p>Under LIHEAP, the federal government makes annual grants to states and territories to operate home energy assistance programs for low-income households. The LIHEAP statute authorizes two types of funds: regular funds, which are allocated to all states using a statutory formula, and emergency contingency funds, which are allocated to one or more states at the discretion of the executive branch in cases of emergency. States and territories may use LIHEAP funds to help low-income households pay for heating and cooling costs, for crisis assistance, weatherization assistance, and services (such as counseling) to reduce the need for energy assistance.</p> <p>The LIHEAP statute provides that at least 0.10 percent (one-tenth of 1.0 percent) but not more than 0.50 percent (one-half of 1.0 percent) of the total regular fund appropriation must be set aside for energy assistance in the five territories. Within that range, HHS sets the exact percentage of funds that goes to the territories. From the inception of the program in the early 1980s through Fiscal Year 2013, HHS established the set-aside at approximately 0.134 percent of regular funds. This percentage was based on the amount of funding that the territories received under LIEAP, the predecessor program to LIHEAP. In FY2014, HHS set aside 0.5 percent of funding for the territories, the first time that funding had reached the maximum allowed by the statute. This set-aside has continued in appropriations since Fiscal Year 2014. HHS apportions funds among the five territories based on population, with Puerto Rico receiving approximately 90 percent of funds. In Fiscal Year 2016, Puerto Rico received \$15.1 million in LIHEAP funds.</p>
<p>Medical Assistance Program (Medicaid)</p>	<p>U.S. Department of Health and Human Services (HHS), Centers for Medicare and Medicaid Services (CMS)</p>	<p>House Committee on Energy and Commerce</p> <p>Senate Committee on Finance</p>	<p>Medicaid is a joint federal-state program that finances the delivery of medical services for low-income individuals. The territories operate Medicaid programs under federal rules that differ from those applicable to the states and DC. For example, most of the eligibility and benefit requirements for the states and DC apply to the territories, but none of the territories cover all the mandatory eligibility groups and benefits. The federal matching rate (FMAP) in the states varies according to a state's per capita income and can range from 50 percent to 83 percent, while DC's FMAP is set by statute at 70 percent. The FMAP for the territories is generally set by statute at 55 percent. Federal Medicaid funding to the states and DC is open-ended, while the Medicaid programs in the territories are subject to federal spending caps (i.e., allotments) pursuant to Section 1108 of the Social Security Act (48 U.S.C. 1308), which are adjusted annually for inflation. Puerto Rico's Section 1108 cap was \$335,300,000 in Fiscal Year 2016. The Patient Protection and Affordable Care Act (ACA; P.L. 111-148, as amended) provided \$7.3 billion in additional Medicaid federal funding to the territories, available between July 1, 2011, and September 30, 2019, of which Puerto Rico received approximately \$6.4 billion. In Fiscal Year 2016, Puerto Rico drew down approximately \$1.63 billion in combined ACA funds (\$1.3 billion) and Section 1108 funds (\$335.3 million), not including federal funding for the Children's Health Insurance Program (CHIP), funding provided through Section 1935(e) of the Social Security Act, sometimes referred to as the enhanced allotment program</p>

			(EAP), or funding for health information and technology.
State Medicaid Fraud Control Units (MFCU)	U.S. Department of Health and Human Services (HHS), Centers for Medicare and Medicaid Services (CMS)	House Committee on Energy and Commerce  Senate Committee on Finance	Section 1902(a)(61) of the Social Security Act requires each state and territory to operate an MFCU to investigate and prosecute Medicaid provider fraud and patient abuse or neglect under state law, unless the state or territory demonstrates to the satisfaction of the HHS Secretary that the operation of an MFCU would not be cost-effective,. Currently, all states (except North Dakota) and the District of Columbia have MFCUs. Provided that a state MFCU is certified (and recertified annually) by the Department of Health and Human Services Office of Inspector General, federal law provides for an enhanced federal medical assistance percentage (FMAP) for MFCUs. None of the five territories operates an MFCU, which is likely a result (at least in part) of the annual federal Medicaid funding cap that applies to the territories. None of the territories has sought or received a waiver from the Secretary.
State Health Insurance Assistance Program (SHIP)	U.S. Department of Health and Human Services (HHS), Administration for Community Living (ACL)	House Committee on Energy and Commerce  Senate Committee on Finance	<p>In the Omnibus Budget Reconciliation Act of 1990 (OBRA 90; P.L. 101-508) Congress authorized and appropriated funding from the Medicare trust funds for a “beneficiary assistance program” to help Medicare beneficiaries receive Medicare, Medicaid, and other health-insurance services. The beneficiary assistance program was later renamed the State Health Insurance Assistance Program (SHIP) and administration of the SHIP program was officially transferred from CMS to the Administration for Community Living (ACL) in 2014.</p> <p>SHIP funding is allocated to states through grants that are required to consider the percentage of Medicare beneficiaries in the state, the rural population, and state administration capacity. Section 119 of the Medicare Improvements for Patients and Providers Act of 2008 (MIPPA, P.L. 110-275) authorized additional appropriations for SHIPs and other outreach assistance programs under the Administration on Aging, a precursor to ACL. The additional MIPPA appropriation, \$13 million annually in Fiscal Year 2016 and Fiscal Year 2017, are allocated based on a statutory formula that relies in part on the percentage of Medicare beneficiaries who are eligible, but do not receive, a low-income subsidy (LIS) through Medicaid. Under Medicaid law, LIS subsidy programs are optional for the territories and none of the territories offer LIS. Thus, territories are not eligible for the additional MIPPA SHIP funding.</p>

Medicare Part A	U.S. Department of Health and Human Services (HHS), Centers for Medicare and Medicaid Services (CMS)	House Committee on Ways and Means  Senate Committee on Finance	<p>Medicare Part A provides coverage for inpatient hospital, skilled nursing facility, home health, and hospice benefits. Eligible hospitals, including hospitals in Puerto Rico, that treat a certain share of low-income patients and are reimbursed under the Medicare Inpatient Prospective Payment System (IPPS) can receive additional payments—Medicare Disproportionate Share Hospital (DSH) payments—to offset the financial effects of treating such patients. Prior to the Patient Protection and Affordable Care Act (ACA; P.L. 111-148, as amended), DSH payments were provided by a single statutory formula that increased the IPPS reimbursement amount based on the disproportionate patient percentage (DPP). The DPP was based on a hospital’s share of low-income patients, defined as the share of Medicare inpatient days for individuals entitled to federal Supplemental Security Income (SSI) benefits out of a hospital’s total Medicare inpatient days (Medicare/SSI) plus the share of Medicaid inpatient days out of the hospital’s total inpatient days.</p> <p>The ACA modified DSH funding for Fiscal Year 2014 and thereafter, splitting DSH into two payments with separate methodologies: (1) empirically justified DSH payments, which continue to be based on the traditional DPP but are reduced to 25 percent of the DSH payments that otherwise would have been provided in the absence of the ACA modification, and (2) uncompensated care payments, which are based on the most appropriate data available and, in the aggregate, are equal to the remaining 75 percent of the pre-ACA DSH amount. Currently, Medicare/SSI is a factor in calculating both payments. Residents of Puerto Rico are ineligible for SSI because the program is not available in the territory. The HHS Secretary, using administrative authority, modified the uncompensated care payment formula for Fiscal Year 2017 to use 14 percent of a Puerto Rico hospital’s Medicaid days as a proxy for Medicare/SSI days, resulting in an estimated \$12.9 million increase rather than an estimated \$3.4 million decrease in total uncompensated care payments to hospitals in Puerto Rico in Fiscal Year 2017 in the absence of the new proxy. The Secretary did not use a proxy for Medicare/SSI in the empirically justified DSH payment formula, citing that the DPP is prescribed in statute for empirically justified DSH. <u>See Social Security Act 1886(d)(5)(F)(vi).</u></p>
Medicare Part B	U.S. Department of Health and Human Services (HHS), Centers for Medicare and Medicaid Services (CMS)	House Committee on Energy and Commerce; House Committee on Ways and Means  Senate Committee on Finance	<p>Medicare Part B provides coverage for physicians’ services, outpatient hospital services, durable medical equipment, outpatient dialysis, and other medical services. Residents of every state and territory other than Puerto Rico who are receiving Social Security benefits are automatically enrolled in both Part A and Part B, and coverage begins the first day of the month they turn 65. Because beneficiaries must pay a premium for Part B coverage, they have the option of turning this coverage down. Disabled individuals who have received cash payments for 24 months under the Social Security disability programs are also automatically enrolled in Part B unless they decline such coverage. Those individuals who are not automatically enrolled in Medicare—e.g., because they have not filed for Social Security benefits—must file an application for Medicare Part A and Part B with the Social Security Administration during their seven-month initial enrollment period (IEP), which begins three months before the month in which they</p>

			<p>turn 65. Beneficiaries who do not sign up for Part B during their IEP, or who drop it and sign up again later, may have to pay a late-enrollment penalty for as long as they are enrolled in Part B. Monthly premiums for Part B may go up 10 percent for each full 12-month period that one could have had Part B but did not sign up for it. Certain low-income beneficiaries may qualify for premium assistance from Medicaid through a Medicare Savings Program (MSP). Beneficiaries in an MSP are not subject to late-enrollment penalties regardless of when they signed up for Medicare.</p> <p>Under federal statute, residents of Puerto Rico who receive Social Security benefits are automatically enrolled in Part A, but not Part B, when they turn 65. Rather, they need to sign up for Part B during their IEP or be subject to a penalty. The lack of an automatic Part B enrollment process in Puerto Rico has resulted in a disproportionate number of Puerto Rican Medicare beneficiaries paying the late-enrollment penalties. Because Puerto Rico does not have an MSP program, low-income beneficiaries subject to this penalty may be responsible for paying the full penalty amount in addition to their premiums.</p>
Medicare Part D	U.S. Department of Health and Human Services (HHS), Centers for Medicare and Medicaid Services (CMS)	House Committee on Energy and Commerce; House Committee on Ways and Means  Senate Committee on Finance	Medicare Part D provides an outpatient prescription drug benefit, either through private prescription drug plans that offer only drug coverage or through Medicare Advantage prescription drug plans that offer coverage as part of broader, managed-care plans. In the states and DC, individuals with incomes up to 150 percent of the federal poverty level and assets below set limits are eligible for assistance with their Part D premiums and cost sharing, which is known as the Part D low-income subsidy (LIS). The states and DC make annual payments, known as clawback payments, to help cover the cost of LIS. Pursuant to federal statute, residents of the territories are not eligible for LIS. In lieu of LIS, federal law provides Medicaid funding to the territories to provide Medicaid coverage of prescription drugs for low-income Medicare beneficiaries. This funding, provided through Section 1935(e) of the Social Security Act, is sometimes referred to as the enhanced allotment program (EAP). Each territory government is required to match the Section 1935(e) funding at its regular Medicaid FMAP rate of 55 percent. This means for every dollar a territory spends on providing Medicaid coverage for prescription drugs to low-income Medicare beneficiaries, the territory draws down \$0.55 from its allotted Section 1935(e) funding, up to annual limit. In Fiscal Year 2015, Puerto Rico received a Section 1935(e) allotment (i.e., the maximum amount of federal funds available for this purpose) of \$44 million, but Puerto Rico used only \$9 million of these funds as a result of the matching requirement.
Health Insurance Exchange Marketplace	U.S. Department of Health and Human Services (HHS), Centers for Medicare and Medicaid Services (CMS)	House Committee on Energy and Commerce; House Committee on Ways and Means  Senate Committee on Finance	The Patient Protection and Affordable Care Act (ACA; P.L. 111-148, as amended) requires health insurance exchanges to be established in every state and DC where individuals and small businesses purchase private health insurance coverage. States must have two types of exchanges: an individual exchange and a small business health options program exchange. Exchanges may be established either by the state itself as a state-based exchange or by the HHS Secretary as a federally-facilitated exchange. Persons who obtain coverage through the individual exchange may be eligible for financial assistance—premium tax credits and cost-

			<p>sharing subsidies—from the federal government, and small businesses that use the small business exchange may be eligible for tax credits to assist businesses with the cost of providing health insurance coverage to employees. Section 1323 of the ACA authorized each territory to elect to establish an exchange, but did not require a territory to do so. A territory that did elect to establish an exchange could receive limited federal funding for the purpose of providing premium and cost-sharing assistance for individuals who enrolled in the exchange. Section 1323 provided \$1 billion to be available for this purpose beginning in 2014 and ending in 2019, with \$925 million allocated to Puerto Rico and \$75 million allocated among the four other territories. If a territory did not establish an exchange, Section 1323 provides that the territory is entitled to an increase in Medicaid funds by the equivalent amount of its Section 1323 funding (in the case of Puerto Rico, \$925 million). No territory elected to establish an exchange and each instead received an increase in its Medicaid funding.</p>
<p>Family-to-Family Health Information Center Grant Program</p>	<p>U.S. Department of Health and Human Services (HHS), Health Resources and Services Administration (HRSA)</p>	<p>House Committee on Energy and Commerce</p> <p>Senate Committee on Finance</p>	<p>The F2F program was established as part of the Family Opportunity Act, which was included in the Deficit Reduction Act of 2005 (P.L. 109-171). Under the program, HRSA makes competitive grants to support Family-to-Family Health Information Centers. Centers are primarily non-profit organizations run by families with children and youth with special health care needs, and they provide education, training, peer support, and expertise in navigating health care systems for other families of children and youth with special health care needs. The law establishing the program makes grants available to support a single center in each of the 50 states and in DC, but not in the U.S. territories. See 42 U.S.C. 701(c)(5). The program is directly funded (not subject to the annual appropriations process) and the current annual appropriation is \$5 million. Funding is distributed equally among centers in each state and DC, with each center receiving about \$95,000 per year, regardless of the state's population.</p>
<p>Federal Home Visiting Program</p> <p>Also known as Maternal, Infant, and Early Childhood Home Visiting Program (MIECHV)</p>	<p>U.S. Department of Health and Human Services (HHS), Health Resources and Services Administration (HRSA)</p>	<p>House Committee on Ways and Means</p> <p>Senate Committee on Finance</p>	<p>The Federal Home Visiting Program supports home visiting services for families with young children who reside in communities that have concentrations of poor child health and other risk indicators. Home visits are conducted by nurses, mental health clinicians, social workers, or others with specialized training. The law does not specify how state and territory grant funds are to be allocated to eligible entities. In practice, HRSA distributes Federal Home Visiting Program funds by both formula and competitive awards and, on its face, the funding formula treats states and territories the same. Between Fiscal Year 2010 and Fiscal Year 2015, funding was distributed according to the relative share of children under age five in families at or below 100 percent of the federal poverty line in each state. The poverty data are derived from the U.S. Census Bureau's Small Area Income Poverty Estimates (SAIPE), which are not available for the territories. There was a \$1 million funding minimum for both state and territory grantees, and HRSA allocated the minimum level of funding to each of the territories from Fiscal Year 2011 through Fiscal Year 2015.</p>

			For Fiscal Year 2016, HRSA redesigned the funding allocation for formula grants. About one-third of funding is allocated based on the share of children under age five in families at or below 100 percent of the federal poverty line in each state, again using 2013 SAIPE data that are not available for the territories. About two-thirds of funding is allocated based on the amount of competitive awards a state or territory received under the Federal Home Visiting Program between Fiscal Year 2013 and Fiscal Year 2015. There continues to be a \$1 million funding minimum for both state and territory grantees, and the territories each received the base allocation of \$1 million in Fiscal Year 2016.
Community Mental Health Services Block Grant (MHBG)	U.S. Department of Health and Human Services (HHS), Substance Abuse and Mental Health Services Administration (SAMHSA)	House Committee on Ways and Means  Senate Committee on Finance	The MHBG is a block grant program that distributes funds to states and territories according to a formula to support community mental health services for adults with serious mental illness and children with serious emotional disturbance. For states and DC, the MHBG allotment formula is based on the population at risk (weighted), the cost of providing services, and taxable resources. The minimum allotment is the amount that the state received in Fiscal Year 1998. Territories are funded pursuant to a different formula. Of MHBG funds appropriated annually, the law requires the HHS Secretary to reserve 1.5 percent for distribution to the territories. Funds are distributed among the territories in amounts proportional to their populations. The minimum allotment for the territories is \$50,000. In Fiscal Year 2016, Puerto Rico received \$6.5 million. See PHS Act 1918; 42 U.S.C. 300x-7.
Substance Abuse Prevention and Treatment Block Grants (SABG)	U.S. Department of Health and Human Services (HHS), Substance Abuse and Mental Health Services Administration (SAMHSA)	House Committee on Ways and Means  Senate Committee on Finance	The SABG is a block grant program that distributes funds to states and territories according to a formula for the purpose of supporting substance abuse prevention and treatment services. State and territories, in turn, may distribute funds to local government entities and non-profit organizations. For the states and DC, the SABG allotment formula is based on the MHBG formula and takes into account the population at risk (unweighted), the cost of services, and taxable resources. The minimum allocation is 0.375 percent of the SABG appropriation. Territories are funded pursuant to a different formula. Of SABG funds appropriated annually, the law requires the HHS Secretary to reserve 1.5 percent for distribution to the territories. Funds are distributed among the territories in amounts proportional to their populations. The minimum allotment for the territories is \$50,000. In Fiscal Year 2016, Puerto Rico received \$22.8 million. See PHS Act 1933; 42 U.S.C. 300x-33.

National Housing Trust Fund (HTF)	U.S. Department of Housing and Urban Development (HUD)	House Committee on Financial Services  Senate Committee on Banking, Housing, and Urban Affairs	The HTF was established by the Housing and Economic Recovery Act of 2008 (P.L. 110-289) to provide formula-based grants to states and territories to use for certain affordable housing activities, with a focus on producing rental housing for extremely low-income households. The HTF is funded through contributions from two government-sponsored enterprises, Fannie Mae and Freddie Mac, rather than through appropriations. The statute establishes a formula that takes into account certain factors related to rental housing for extremely low-income and very low-income households. The statute also specifies a minimum allocation for the 50 states and DC of \$3.0 million, but the minimum allocation does not apply to Puerto Rico and the other territories. HUD announced the first state allocations from the HTF in May 2016, made from funds that were set aside by Fannie Mae and Freddie Mac during calendar year 2015. Fifteen states received an amount greater than the minimum allocation of \$3.0 million (and, of those 15, five have allocations above \$4.0 million), while 35 states and DC received the minimum allocation of \$3.0 million. Puerto Rico received \$326,000.
Pittman-Robertson Fund/Federal Aid in Wildlife Restoration (Wildlife Restoration, Basic Hunter Education, Enhanced Hunter Education)	U.S. Department of the Interior (DOI), Fish and Wildlife Service (FWS)	House Committee on Natural Resources  Senate Committee on Environment and Public Works	The Pittman-Robertson Wildlife Restoration Act (WRA) uses the proceeds from a federal excise tax (on pistols, revolvers, shells, cartridges, archery equipment) to fund matching grants to states and territories for projects to benefit wildlife resources and conduct hunter education programs, with revenues going into an account called the Wildlife Restoration Fund administered by FWS. The appropriation of these funds is mandatory, indefinite spending. Distribution of funding is by formula. First, \$8 million is set aside for Enhanced Hunter Education to construct or maintain public target ranges. No more than one-sixth of 1.0 percent may be provided to each territory, while allocations to states are based on population. In Fiscal Year 2016, Puerto Rico and the other territories each received \$13,400. Next, one-half of the excise tax on pistols, revolvers, bows, and arrows (but not firearms) is set aside for Basic Hunter Education. As before, no more than one-sixth of 1 percent may be provided to each territory, while allocations to states are based on population. In Fiscal Year 2016, Puerto Rico and the other territories each received \$204,230. The remaining amount forms the bulk of the program for Wildlife Restoration. No more than one-half of 1 percent may be provided to Puerto Rico (or one-sixth of 1 percent in the case of the other territories), while allocations to states are based on a formula involving numbers of licensed hunters and state acreage. In Fiscal Year 2016, Puerto Rico received \$2,881,535.
State Wildlife Grants (SWG)	U.S. Department of the Interior (DOI), Fish and Wildlife Service (FWS)	House Committee on Appropriations  Senate Committee on Appropriations	The SWG program provides matching funds to state and territory fish and wildlife agencies to develop and implement programs that benefit wildlife and their habitats. Funding may be used to address a variety of conservation needs—such as research, fish and wildlife surveys, species restoration, habitat management, and monitoring—that are identified in a state or territory's Wildlife Action Plan. A portion of the funds appropriated is for formula grants and the other portion is for competitive grants. The program was created in P.L. 106-291 and further detailed in subsequent Interior appropriations laws; it has no separate

			authorizing statute and is a program that was originally created by the Appropriations Committees. With respect to the funds appropriated for formula grants, appropriations law provides that the allocation formula is based two-thirds on the population of each state and one-third on the land area of each state. No state may receive less than 1.0 percent or more than 5.0 percent of the amount allocated. Neither Puerto Rico nor DC may receive more than one-half of 1.0 percent, and the other territories may not receive more than one-fourth of 1.0 percent. In Fiscal Year 2016, Puerto Rico received \$241,087 in SWG formula funding and \$7,545 in competitive grants.
Dingell-Johnson Sport Fish Restoration Grants	U.S. Department of the Interior (DOI), Fish and Wildlife Service (FWS)	House Committee on Natural Resources  Senate Committee on Environment and Public Works	Excise taxes on fishing equipment, motorboat and small engine fuels, import duties, and interest are collected and appropriated from the Sport Fish Restoration and Boating Trust Fund. The Fund has a mandatory, permanent appropriation. The matching funds are made available to states and territories through grants, with funding allocated pursuant to a formula. Under Section 4 of the Dingell-Johnson Sportfish Restoration Act, no state may receive less than 1.0 percent or more than 5.0 percent of the amount allocated. Under Section 12 of the Act, neither Puerto Rico nor DC may receive more than 1.0 percent, and the other territories may not receive more than one-third of 1.0 percent. In Fiscal Year 2016, Puerto Rico received \$3,555,272 in Sport Fish Restoration grants. (Eleven states also received the same allocation of one percent.) Five other subprograms are also included in this Fund; allocation is through competitive grants. In Fiscal Year 2016, Puerto Rico did not receive any of these grants.
Land and Water Conservation Fund, State Assistance Program	U.S. Department of the Interior (DOI), National Park Service (NPS)	House Committee on Natural Resources  Senate Committee on Energy and Natural Resources	The Land and Water Conservation Fund (LWCF) Act of 1965—enacted to help preserve, develop, and ensure access to outdoor recreation resources—created the Land and Water Conservation Fund. The Fund is currently authorized through September 30, 2018, to accrue revenues of \$900 million annually from three specific sources: revenues from oil and gas leases on the Outer Continental Shelf (OCS), the federal motorboat fuel tax, and surplus property sales. A portion of the LWCF, administered by the NPS, provides matching grants to states, DC and the territories for recreation planning, acquisition of lands and waters, and facility development. To be eligible for a grant, a state or territory must prepare and update a statewide outdoor recreation plan. Under the statutory formula, a portion of the State Assistance appropriation is divided equally among 51 jurisdictions—(1) each of the 50 states and (2) the five territories and DC, which together are considered one state. This “state” share is divided among the five territories and DC in accordance with population. The remaining State Assistance appropriation is apportioned based on need, as determined by the Secretary of the Interior, taking into consideration factors in law, among others. For this purpose, the five territories and DC are each treated as separate states. In Fiscal Year 2016, Puerto Rico received a total of \$1.3 million in LWCF funding under the state grant program.
Federal Aid-Highway Program (FAHP)	U.S. Department of Transportation (DOT), Federal Highway Administration (FHWA)	House: Committee on Transportation and Infrastructure; House Committee on Ways and Means (for tax	FAHP is an umbrella term for the separate highway programs administered by the FHWA. Under the 2015 surface transportation reauthorization act—FAST Act (P.L. 114-94)—most FAHP funding is distributed through the following formula-based programs: (1) National Highway Performance Program, (2) Surface Transportation Block Grant Program, (3) Highway Safety

		<p>issues)</p> <p>Senate Committee on Environment and Public Works; Senate Committee on Finance (for tax issues)</p>	<p>Improvement Program, (4) Congestion Mitigation and Air Quality Improvement Program, (5) National Highway Freight Program, and (6) Metropolitan Planning Program. The FAST Act provides for a single gross apportionment to each state and DC, which is then divided up among the various programs. For purposes of apportioning federal-aid highway funds, Puerto Rico is not considered a state. Instead, funds are authorized for a stand-alone program called the Puerto Rico Highway Program. Under Section 1115 of the FAST Act, funding for the Puerto Rico Highway Program is authorized at \$158 million annually from Fiscal Year 2016 through Fiscal Year 2020. However, because Puerto Rico is subject to penalties under 23 U.S.C. Section 154 (Open Container Requirements), Section 158 (National Minimum Drinking Age), and Section 164 (Repeat Offenders driving while Intoxicated or driving under the influence), the \$158 million is reduced (for Fiscal Year 2016, the reduction was approximately \$15.7 million or about 10 percent). Current law directs Puerto Rico Highway Program funding to be used as follows: 50 percent for purposes eligible under the National Highway Performance Program (essentially, on National Highway System roads in Puerto Rico), 25 percent for purposes eligible under the Highway Safety Improvement Program (for safety infrastructure), and 25 percent for any purpose allowable under the Highway title of the U.S. Code (Title 23). The FAHP, as well as the Puerto Rico Highway Program, rely upon revenues from the Highway Account of the Highway Trust Fund, which is financed from a federal excise tax on motor fuels, as well as a federal tax on tires, truck and trailer sales, and heavy-vehicle use. Federal law does not impose the excise tax on motor fuel, or the other federal taxes, in Puerto Rico.</p>
<p>Motor Carrier Safety Assistance Program (MCSAP)</p>	<p>U.S. Department of Transportation (DOT), Federal Motor Carrier Safety Administration (FMCSA)</p>	<p>House Committee on Transportation and Infrastructure</p> <p>Senate Committee on Commerce, Science, and Transportation</p>	<p>The Motor Carrier Safety Assistance Program (MCSAP) is a formula grant program that provides financial assistance to states and territories to reduce the number and severity of accidents and hazardous materials incidents involving commercial motor vehicles. MCSAP grants are provided annually to the state's MCSAP lead agency, which is designated by the governor as the state motor vehicle safety agency responsible for administering the Commercial Vehicle Safety Plan within the state. There are two categories of MCSAP grants: Basic grants and Incentive grants. Basic grants are distributed pursuant to a formula that involves highway miles, vehicle miles traveled, population, and special fuel consumption. All states, DC, and the territories are eligible for Basic grants. There is a 20 percent match requirement on the part of the state lead MCSAP agency, but the state lead MCSAP agency in the four territories other than Puerto Rico are exempt from this match requirement. In addition, a state lead MCSAP agency may qualify for Incentive grants if it can demonstrate that its commercial vehicle safety program has shown improvement in certain areas. Puerto Rico and the other territories are not currently eligible for Incentive grants, evidently because the safety performance and data quality factors on which the Incentive grants are based are not available for the territories. In Fiscal Year 2016, Puerto Rico received an MCSAP Basic Grant of \$1,146,134.</p>

<p>Growing States and High Density States Program</p>	<p>U.S. Department of Transportation (DOT), Federal Transit Administration (FTA)</p>	<p>House Committee on Transportation and Infrastructure</p> <p>Senate Committee on Banking, Housing, and Urban Affairs</p>	<p>Under 49 U.S.C. 5340, funds are authorized from the Mass Transit Account of the Highway Trust Fund for two programs: the Growing State Formula Program (Section 5340(c)) and the High Density State Formula Program (Section 5340(d)). Funding from these two programs can be used by recipients for a wide variety of purposes, including capital projects, planning and, in certain circumstances, operating costs. The programs are authorized through Fiscal Year 2020. In Fiscal Year 2016, the Growing States Formula Program was authorized at \$272.3 million and the High Density States Formula Program at \$264.0 million. Funding for the Growing States Formula Program is apportioned among states based on the projected population of each state 15 years beyond the most recent decennial census. Funding is distributed to urbanized areas and rural areas within a state based on projections of the distribution of population. Funding for the High Density State Formula Program is apportioned to states with a population density greater than 370 persons per square mile. Currently, seven states qualify: Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Delaware, and Maryland. Funds are distributed within states to urbanized areas only. Puerto Rico, the other territories and DC are not included within the definition of “state” in 49 U.S.C. 5340(a) and are therefore ineligible for funding under both the Growing State Formula Program and the High Density State Formula Program. According to the 2010 decennial census, Puerto Rico has a population density of 478 persons per square mile, trailing only New Jersey (and DC).</p>
---	--	--	---

**Appendix 3: Treatment of Puerto Rico Under Major U.S. Census Bureau Statistical Programs**

<b>Table of Major U.S. Census Bureau Statistical Programs</b>					
<b>Name of Program</b>	<b>Other Federal Agency Involved?</b>	<b>Description of Program</b>	<b>Does program collect and publish state-by-state information?</b>	<b>If yes, is Puerto Rico included?</b>	<b>If no, is PR data collected and published as part of the national or regional totals?</b>
Census of Governments (six associated annual surveys directly below)	No	The Census of Governments, which is conducted every five years, identifies the scope and nature of the nation's state and local government sector; provides benchmark figures of public finance and public employment; classifies local government organizations, powers, and activities; and measures federal, state, and local fiscal relationships. The Census of Governments is comprised of the following six surveys on this list: Annual Survey of State Government Finance, Annual Survey of Local Government Finance, Annual Survey of Public Employment and Payroll, Annual Survey of Public Pensions, Annual Survey of School System Finances, Annual Survey of State Government Tax Collections. The years ending in "2" and "7" for these annual surveys are considered the Census of Governments years, and data are collected from all governments units as compared with a sample of government units in the other years.	Yes	No	N/A
Annual Survey of State Government Tax Collections (STC)	No	Provides a summary of taxes collected by state for 5 broad tax categories and up to 25 tax subcategories. These tables and data files present the details on tax collections by type of tax imposed and collected by state governments.	Yes	No	N/A
Annual Survey of State Government Finances	No	Provides statistics on revenue, expenditure, debt, and assets (cash and security holdings) for state governments. There are statistics for the 50 states and DC, as well as a national summary.	Yes	No	N/A
Annual Survey of Local Government Finances	No	Provides statistics on revenue, expenditure, debt, and assets (cash and security holdings) for local governments. There are statistics for the 50 state areas and the District of Columbia, as well as a national summary.	Yes	No	N/A
Annual Survey of Public Employment & Payroll (APES)	No	Provides state and local government data on full-time and part-time employment, part-time hours worked, full-time equivalent employment, and payroll statistics.	Yes	No	N/A

Annual Survey of Public Pensions	No	Provides revenues, expenditures, financial assets, and membership information for the defined benefit public pensions. Data are shown for individual pension funds and systems as well as at the national, state, and local level. There were 299 state-administered funds and 6,000 locally-administered defined benefit public pension systems, all of which are represented here.	Yes	No	N/A
Annual Survey of School System Finances	National Center for Education Statistics (NCES)	Provides statistics about the finances of elementary and secondary public school systems. Education finance data include revenues, expenditures, debt, and assets of elementary and secondary public school systems. Statistics cover school systems in all states and DC. This survey is co-funded by the National Center for Education Statistics, which has a stake in the survey content and data products.	Yes	No	N/A
Decennial Census of Population and Housing	No	The Decennial U.S. Census counts every resident in the United States. It is mandated by Article I, Section 2 of the Constitution and takes place every 10 years.	Yes	Yes	N/A
Economic Census	No	The Economic Census is the U.S. Government's official five-year measure of American business and the economy for planning and key economic reports, and economic development and business decisions. The last Economic Census was conducted during the year ending December 2012. In October through December 2012, nearly 4 million businesses in America received an economic census form, including most businesses with paid employees.	Yes	No, but PR is included in the Economic Census of Islands Areas	No
Advance Monthly Retail Trade and Food Services Survey (MARTS)	No	Census conducts MARTS to provide an early estimate of monthly sales by kind of business for retail and food service firms located in the United States. Each month, questionnaires are mailed to approximately 4,700 employer firms selected from the larger Monthly Retail Trade Survey (MRTS). No questionnaires are mailed to firms in PR.	No	N/A	No
American Community Survey	No	Premier source for information about America's changing population, housing and workforce.	Yes	Yes, via equivalent Puerto Rico Community Survey	N/A
American Housing Survey (AHS)	Department of Housing and Urban Development (HUD)	AHS is sponsored by HUD and conducted by Census. The survey is the most comprehensive national housing survey in the United States. The AHS is conducted biennially between May and September in odd-numbered years.	No, AHS produces national and regional statistics; statistics for the 15 largest metropolitan areas; and statistics for other selected metropolitan	No, HUD has never chosen San Juan as one of the selected metro areas.	No, PR is not included in the sample design.

			areas (usually 10-15 each survey cycle).		
American Time Use Survey (ATUS)	Department of Labor, Bureau of Labor Statistics (BLS)	ATUS measures the amount of time people spend doing various activities, such as paid work, childcare, volunteering, and socializing. ATUS data are collected via telephone interviews. Households that have completed their final (8th) month of the Current Population Survey (CPS) are eligible for the ATUS.	No	N/A	No, because PR households do not participate in the CPS.
Annual Capital Expenditures Survey (ACES)	No	ACES provides data on capital spending for new and used structures and equipment by U.S. nonfarm businesses.	No	N/A	No, businesses in PR and the other territories are excluded.
Annual Retail Trade Survey (ARTS)	No	Provides estimates on sales, e-commerce sales, end-of-year inventories, methods of inventory valuation, purchases, and operating expenses.	No	N/A	No
Annual Survey of Entrepreneurs (ASE)	Department of Commerce, Minority Business Development Agency (MBDA)	Provides estimates of number of firms, sales/receipts, annual payroll, and employment by gender, ethnicity, race, and veteran status. The ASE is a supplement to the Survey of Business Owners (SBO), which is conducted every five years as part of the Economic Census. ASE collection is electronic only. The estimate of the sample is approximately 290,000 employer businesses in operation during the survey year. Those selected for the survey receive an initial letter informing the respondents of their requirement to complete the survey.	No	N/A	No
Annual Survey of Manufactures (ASM)	No	Provides estimates on manufacturing activity, products, and location for the public and private sectors.	Yes	No	N/A
Annual Wholesale Trade Survey (AWTS)	No	Provides estimates on sales, e-commerce sales, end-of-year inventories, methods of inventory valuation, purchases, and operating expenses. The Monthly Wholesale Trade Survey (MWTS) and the AWTS work together to produce the most comprehensive data available on wholesale economic activity in the United States.	No	N/A	No
Boundary and Annexation Survey (BAS)	No	Census conducts the BAS annually to collect information about selected legally defined geographic areas. The BAS is used to update information about the legal boundaries and names of all governmental units in the United States.	Yes	Yes	N/A

Building Permits Survey (BPS)	No	Provides national, state, and local statistics on new privately-owned residential construction. Building permits data are collected from individual permit offices, most of which are municipalities. Data are also collected for PR and other U.S. territories, although these areas are excluded from the national statistics.	Yes	Yes, but data for states is published monthly and data for PR is published annually.	No
Business Dynamics Statistics (BDS)	No	Provides annual measures of business dynamics (such as job creation and destruction, establishment births and deaths, and firm startups and shutdowns) for the economy and aggregated by establishment and firm characteristics.	Yes	<b>No</b>	N/A
Business R&D and Innovation Survey (BRDIS)	National Science Foundation (NSF)	Provides data on R&D activities of companies operating in the United States, as well as statistics on the R&D workforce, intellectual property, technology transfer activities and innovation, which is useful to decision makers in both the public and private sectors.  A mail-out/mail-back sample survey of approximately 40,000 companies with 5 or more employees. Large companies with known R&D above \$3 million from the previous survey cycle are selected each year from the Business Register.	Yes	<b>No</b> , PR companies are not included in the sample.	No
Commodity Flow Survey (CFS)	Bureau of Transportation Statistics (BTS)	The CFS, undertaken through a partnership between the Census Bureau and BTS, is conducted every 5 years (years ending in “2” and “7”) as part of the Economic Census. The CFS produces data on the movement of goods in the United States, providing information on commodities shipped, their value, weight, and mode of transportation, as well as the origin and destination of shipments of commodities from manufacturing, mining, wholesale, and selected retail and services establishments. Beginning with the 2007 CFS, a sample of 100,000 establishments from the mining, manufacturing, wholesale, and selected retail industries is selected based on geographic location and industry.	Yes	<b>No</b>	N/A
Construction Progress Reporting Survey (CPRS)	No	Provides monthly estimates on the total dollar value of construction work done in the U.S. Composite estimates are based on mail-out/mail-back and interview surveys of selected construction projects and building owners, and estimates developed or compiled from other sources. These four surveys currently cover about 6,500 private nonresidential, 10,500 state and local, 1,500 multi-family, and 700 federal projects each month.	Yes. Statistics are available at the U.S. level monthly, and by division, region, and state annually for selected categories.	<b>No</b> , PR is excluded from state, regional and national totals.	N/A

Consumer Expenditure Survey (CE)	BLS	The CE program consists of the Quarterly Interview Survey and the Diary Survey, which provide information on the buying habits of American consumers, including data on their expenditures, income, and consumer unit (families and single consumers) characteristics. The survey data are collected for BLS by the Census Bureau.	Expenditures at the state level are not calculated or published, but geographic-specific data is published.	N/A	No
County Business Patterns	No	CBP is an annual series that provides subnational economic data by industry. This series includes the number of establishments, employment during the week of March 12, first quarter payroll, and annual payroll. This is not a survey, but rather a data product that relies on administrative records, the Company Organization Survey, and the Economic Census as inputs. PR is included in the CBP, although its data is published with the other territories in a separate <a href="#">file</a> .	Yes	Yes	N/A
Current Population Survey (CPS)	BLS	The CPS is a monthly survey sponsored by BLS and conducted by the U.S. Census Bureau. It is the primary source of labor force statistics for the population of the United States.	Yes	No	N/A
Economic Census of Islands Area (IA)	No	The Economic Census of Island Areas is the U.S. Government's official five-year measure of businesses and the economy used for planning, economic development, and business decisions. The last Economic Census was conducted for the year ending in December 2012. The Census Bureau mailed a questionnaire to all employer firms in PR that were classified as in-scope for the Economic Census. The Census Bureau covered roughly 38,000 establishments in PR. Respondents were instructed to reply either by mail or on-line. A telephone follow-up was conducted to obtain information from selected firms that failed to report. The Economic Census of Island Areas covers the five US territories. Data collected include total sales, receipts or revenue, kind of business, legal form of organization, employment, annual and first quarter payroll, and class of customer. Hotels, and other lodging places report additional data on sources of receipts and number of accommodations.	Yes, separate statistics are published for PR and each of the other territories	Yes	N/A
Enterprise Statistics Program (ESP)	No	The Enterprise Statistics Program (ESP) collects enterprise level data from the Report of Organization Survey (also known as the Company Organization Survey, or COS). The COS is an annual survey whose purpose is to obtain current organization and operating information on large multi-establishment enterprises in order to maintain the Business Register (BR). The BR is a multi-relational database that contains a record for each	No	N/A	No

		establishment that is located in the U.S. or Puerto Rico and has employees.			
Export Statistics	Bureau of Economic Analysis (BEA); U.S. Customs and Border Protection (CBP)	Provides detailed statistics on goods and services shipped to and from the U.S. and foreign countries. The United States Code, Title 13, requires this program. Participation is mandatory. This is covered under the International Trade Statistics Program.	Yes	Yes	N/A
Federal Audit Clearinghouse	Office of Management and Budget (OMB)	FAC operates on behalf of the Office of Management and Budget (OMB). Its primary purposes are to: distribute single audit reporting packages to federal agencies; support OMB oversight and assessment of federal award audit requirements; and maintain a public database of completed audits. Data is collected from entities in PR that expend federal awards, but data is not used in national and/or regional totals.	No	N/A	No
Government Units Survey	No	Identifies local governments for the Census of Governments, from which PR is excluded, and provides selected data on local governments. Previously known as "Directory Survey of Local Governments."	Yes	No	N/A
Housing Vacancy Survey (HVS)	No	The HVS is a Census Bureau-sponsored section within the Current Population Survey questionnaire that is conducted to inform on vacant housing units. It is not a stand-alone survey. Provides current information on rental and homeowner vacancy rates, and characteristics of units available for occupancy. These data are used by public and private sector organizations to evaluate the need for new housing programs and initiatives. In addition, the rental vacancy rate is a component of the index of leading economic indicators and is thereby used by the Federal Government and economic forecasters to gauge the current economic climate. Rental and homeowner vacancy rates and homeownership rates are available for the U.S., regions, states, and for the 75 largest Metropolitan Statistical Areas (MSAs).	Yes	No	No

Import Statistics	BEA; CBP	Provides detailed statistics on goods and estimates of services entering the U.S. from foreign countries. This is covered under the International Trade Statistics Program.	Yes	Yes	Yes
Longitudinal Employer-Household Dynamics (LEHD)		<p>Under the Local Employment Dynamics (LED) Partnership, states agree to share Unemployment Insurance earnings data and Quarterly Census of Employment and Wages (QCEW) data with the Census Bureau. The LEHD program combines these administrative data, additional administrative data and data from censuses and surveys creating statistics on employment, earnings, and job flows at detailed levels of geography and industry and for different demographic groups. The LEHD program uses these data to create partially synthetic data on workers' residential patterns. Data products released by LEHD include the Quarterly Workforce Indicators (QWI), the LEHD Origin Destination Employment Statistics (LODES), and Job-to-Job Flows (J2J). QWI is the most likely product to be available for PR in the short term. 49 states, the District of Columbia, Puerto Rico, and the U.S. Virgin Islands have joined the LED Partnership, although the LEHD program is not yet producing public-use statistics for PR or the USVI.</p> <p>Data have been collected from Puerto Rico but have not been published because of quality issues with the input files. Census is currently working with its partners in Puerto Rico to address these issues with input files.</p>	Yes	<b>Not in practice.</b>	N/A
Manufactured Housing Survey	HUD	MHS is sponsored by HUD and collected by the Census Bureau, and provides data on shipments, prices and characteristics of new manufactured housing. Key statistics include "Shipments by State." Estimates of Average Sales Price of Manufactured Homes Sold or Intended for Sale for Residential Use are available at national, region, division, and state level annually and region level monthly. Estimates of Manufactured Home Shipments are available at the national and state level monthly. Estimates of shipped homes by status are available at the national level monthly. Estimates of selected characteristics of sold/placed homes are available by region.	Yes	<b>No</b>	No
Manufacturers' Shipments, Inventories, and Orders Survey (M3)	No	Provides monthly estimates on current economic conditions and indications of future production commitments in the manufacturing sector.	No	N/A	No

Manufacturers' Unfilled Orders Survey (M3UFO)	No	Collects data used to benchmark the new and unfilled orders information published in the monthly M3.	No	N/A	No
Manufacturing Energy Consumption Survey (MECS)	Department of Energy, Energy Information Administration (EIA)	Provides estimates on energy consumption in the manufacturing sector.	No	N/A	No
Medical Expenditure Panel Survey (MEPS)	Department of Health and Human Services, Agency for Healthcare Research and Quality (AHRQ)	MEPS is a set of large-scale surveys of families and individuals, their medical providers (doctors, hospitals, pharmacies, etc.), and employers across the United States. MEPS collects data on the specific health services that Americans use, how frequently they use them, the cost of these services, and how they are paid for, as well as data on the cost, scope, and breadth of health insurance held by and available to U.S. workers.	Yes	<b>No</b>	No
Monthly Retail Trade Survey (MRTS)	No	Provides monthly estimates on sales at retail and food services stores and inventories held by retail stores.	No	N/A	No
Monthly Wholesale Trade Survey (MWTS)	No	Provides monthly estimates of sales and inventories of wholesale trade industries.	No	N/A	No
National Ambulatory Medical Care Survey	CDC, National Center for Health Statistics (NCHS)	NAMCS is a national survey designed to meet the need for objective, reliable information about the provision and use of ambulatory medical care services in the United States. Findings are based on a sample of visits to non-federal employed office-based physicians who are primarily engaged in direct patient care.	No	N/A	No
National Health Interview Survey (NHIS)	NCHS	NHIS data are collected through personal household interviews. For over 50 years, the U.S. Census Bureau has been the data collection agent for the National Health Interview Survey. Survey results have been instrumental in providing data to track health status, health care access, and progress toward achieving national health objectives. An estimated 35,000 completed sample adult interviews and 12,000 completed sample child interviews are expected to be available annually for analysis in the redesigned NHIS. There are numerous data reports linked to—based on—NHIS. In the geographic classification of the U.S. population, states are grouped into the four regions used by the U.S. Census Bureau; PR is not included in any region. NCHS collects Vital Statistics (birth and death certificate data) for Puerto Rico through the National Vital Statistics System. But no information is collected in PR for other NCHS surveys. NCHS surveys target the resident civilian non-institutionalized population using the Census definition of this population which is defined as the 50 states and DC. The target population does not include persons residing	In general no, although there is state-by-state information for estimates of health insurance coverage and variation in health care service utilization. There is no PR-specific data.	<b>No</b>	No

		outside the 50 states and DC.			
National Hospital Ambulatory Care Survey (NHAMCS)	NCHS	The National Hospital Ambulatory Medical Care Survey (NHAMCS) is designed to collect data on the utilization and provision of ambulatory care services in hospital emergency and outpatient departments. Findings are based on a national sample of visits to the emergency departments and outpatient departments of non-institutional general and short-stay hospitals.	No, national and regional only.	N/A	No
National Sample Survey of Registered Nurses	Department of Health and Human Services (HHS)	Conducted every four years since 1977. The data from these periodic surveys provide the basis for evaluating trends and projection of the future supply of nursing resources. Sponsored by the Department of Health and Human Services' Health Resources and Services Administration (DHHS/HRSA), the NSSRN was last conducted by an organization other than Census in 2008. HRSA recently approached Census for the purposes of redesigning the survey, and it is anticipated that we will field the new version of the survey for the first time in January, 2018.	Yes	No	N/A
National Survey of Children's Health (NSCH)	HHS	Examines the physical and emotional health of children ages 0-17 years of age.	Yes	No	No
National Survey of College Graduates (NSCG)	National Science Foundation (NSF)	Biennial survey of college graduates residing in the United States. Sponsored by the National Science Foundation and conducted by the Census Bureau. The survey provides data on the number and characteristics of individuals with a bachelor's or higher degree, with a special focus on individuals with education and/or employment in science or engineering. NSF uses the information to prepare congressionally mandated biennial reports such as Women, Minorities and Persons with Disabilities in Science and Engineering and Science and Engineering Indicators.	In general, no. Although some state information was collected, the state-by-state estimates were not as reliable and were never published.	N/A	Yes. PR is included in the national total, but four other territories are not.
National Survey of Fishing, Hunting, and Wildlife-Associated Recreation	US Fish and Wildlife Service (FWS)	Partnership effort with the States and national conservation organizations, and has become one of the most important sources of information on fish and wildlife recreation in the United States. Quantifies the economic impact of wildlife-based recreation. Federal, State, and private organizations use this detailed information to manage wildlife, market products, and look for trends. The 2011 Survey is the twelfth in a series of surveys conducted about every 5 years since 1955.	Yes	No	No

Nonemployer Statistics	No	An annual series that provides subnational economic data for businesses that have no paid employees and are subject to federal income tax. The data consist of the number of businesses and total receipts by industry. Most nonemployers are self-employed individuals operating unincorporated businesses (known as sole proprietorships). This is not a survey, but rather a data product that primarily relies on administrative records as input.	Yes	No	N/A
Population Estimates	No	Produces estimates of the population for the United States, its states, counties, cities, and towns, as well as for Puerto Rico.	Yes	Yes	N/A
Population Projections	No	Population projections are typically based on an estimated population consistent with the most recent decennial census and are produced using the cohort-component method. The Census Bureau does not have a current set of state population projections and currently has no plans to produce them. PR residents are not included in the 2014 National Population Projection. However, PR projections have been done in the past in a separate program and may be done again in future.	Yes, but the data is old.	No, although PR is included in the projections prepared by Census as part of its International Database Program.	No, PR was not included in 2014 national population projection.
Puerto Rico Community Survey (PRCS)	No	Part of the Census Bureau's annual American Community Survey (ACS), customized for Puerto Rico.	Yes, PR only	Yes	Yes
Quarterly Financial Report (QFR)	No	Provides quarterly aggregate statistics on the financial results and position of U.S. corporations.	No	N/A	No
Quarterly Services Survey (QSS)	No	The only data source providing timely estimates of revenue and expenses for selected service industries.	No	N/A	No
Quarterly Summary of State and Local Government Tax Revenue (QTAX)	No	Provides quarterly estimates of state and local government tax revenue at a national level, as well as detailed tax revenue data for individual states.	Yes	No	N/A
Quarterly Survey of Plant Capacity Utilization (QPC)	Federal Reserve Board, Defense Logistics Agency (DLA)	Collects statistics on establishment operational status, value of actual production, estimated production attainable at full and emergency conditions, and reasons for operating at less than full production capacity.	No	N/A	No
Quarterly Survey of Public Pensions	No	Quarterly survey that provides national summary data on the revenues, expenditures, and composition of assets of the largest defined benefit public employee pension systems for state and local governments. This survey currently consists of a panel of 100 pension systems, which comprise 88.4 percent of financial activity among such entities, based on the 2012 Census of Governments.	No	N/A	No

Quarterly Workforce Indicators (QWI)	No	The QWI are a set of economic indicators including employment, job creation, earnings, and other measures of employment flows. The QWI are reported based on detailed firm characteristics (geography, industry, age, size) and worker demographics information (sex, age, education, race, ethnicity) and are available tabulated to national, state, metropolitan/micropolitan areas, county, and Workforce Investment Board (WIB) areas.	Yes	No	No
Rental Housing Finance Survey (RHFS)	HUD	Provides current and continuous measure of financial, mortgage and property characteristics of multifamily rental housing properties in the United States.	No, only national or regional statistics.	N/A	No
School Crime Supplement to the National Crime Victimization Survey (SCS/NCVS)	NCES; Bureau of Justice Statistics (BJS)	Created as a supplement to the National Crime Victimization Survey (NCVS), the SCS collects information about victimization, crime, and safety at school. The SCS is a national survey of approximately 6,500 students ages 12 through 18 in U.S. public and private elementary, middle, and high schools. None of the 6,500 students are from PR.	No	N/A	No
School Survey on Crime and Safety (SSOCS)	NCES	The primary source of school-level data on crime and safety for NCES. Over 3,000 public school principals are selected to receive the SSOCS questionnaire. None of the 3,000 public school principals selected to receive the SSOCS questionnaire are from PR.	No	N/A	No
Service Annual Survey (SAS)	No	Collects data from companies whose primary business is to provide services to individuals, businesses, and governments. Includes most personal, business, automotive, amusement and recreation, social welfare, health care, and other professional services. This is a survey of approximately 72,000 selected service businesses with paid employees. To be eligible for the list sample, service businesses must be in the Business Register List (BR), which contains all Employer Identification Numbers (EINs) for listed businesses and all locations of multi-establishment companies.	No	N/A	No
Small Area Health Insurance Estimates (SAHIE)	No	The SAHIE produces single-year estimates of health insurance coverage for all counties and states by detailed demographic and income groups. SAHIE data can be used to analyze geographic variation in health insurance coverage, as well as disparities in coverage by race/ethnicity, sex, age and income levels that reflect thresholds for state and federal assistance programs.	Yes	No	N/A

Small Area Income and Poverty Estimates (SAIPE)	No	SAIPE are produced for school districts, counties, and states. The main objective of this program is to provide updated estimates of income and poverty statistics for the administration of federal programs and the allocation of federal funds to local jurisdictions. Estimates for 2014 were released in December 2015. These estimates combine data from administrative records, post-censal population estimates, and the decennial census with direct estimates from the American Community Survey to provide consistent and reliable single-year estimates. These model-based single-year estimates are more reflective of current conditions than multi-year survey estimates.	Yes	No	N/A
Small Business Lending Survey	Federal Deposit Insurance Corporation (FDIC)	The survey will provide insight into many aspects of small business lending, including important (heretofore unavailable) nationally representative information on the general characteristics of small business borrowers to which the banks lend, the types of credit offered to small businesses (such as closed-end loans, lines-of-credit, and credit cards), and the relative importance of commercial lending activity for banks of different sizes and business models and banks with different levels of urban or rural presence.	No	N/A	No
State Government R&D Survey (SGRD)	NSF	The only source for comprehensive, uniform statistics regarding the extent of R&D activity performed and funded by departments and agencies in each of the nation's 50 state governments, the government of DC, and the government of Puerto Rico.	Yes	Yes	N/A
Statistics of U.S. Businesses (SUSB)	Small Business Administration (SBA)	Annual series that provides national and subnational data on the distribution of economic data by enterprise size and industry. SUSB covers most of the country's economic activity. Data are presented by geographic area, industry detail, and enterprise size. Annual data consist of number of firms, number of establishments, annual payroll, and employment during the week of March 12. In addition, estimated receipts data are included for years ending in 2 and 7. A compilation of data is extracted from the Business Register (BR).	Yes	No. All SUSB data are produced as cost-reimbursable special tabulations. There is no appropriated funding.	N/A

Survey of Business Owners and Self-Employed Persons (SBO)	No	<p>The SBO provides the only comprehensive, regularly collected source of information on selected economic and demographic characteristics for businesses and business owners by gender, ethnicity, race, and veteran status. Estimates include the number of employer and nonemployer firms, sales and receipts, annual payroll, and employment. Data aggregates are presented by states, metropolitan and micropolitan statistical areas, counties, places, and employment and receipts size.</p> <p>Businesses were eligible to be selected for this survey if they reported any business activity on any one of the following Internal Revenue Service tax forms: 1040 (Schedule C), 1065, (U.S. Return of Partnership Income), any one of the 1120 corporation tax forms, 941, (Employer's Quarterly Federal Tax Return), and 944, (Employer's Annual Federal Tax Return)</p>	Yes	No	No
Survey of Construction (SOC)	HUD	<p>Provides current national and regional statistics on starts, completions, and characteristics of new, privately-owned single-family and multifamily housing units and on sales of new single-family houses. HUD partially funds this survey.</p> <p>BEA uses the estimates in development of the national income and product accounts. The Federal Reserve Board and Council of Economic Advisers use the estimates to determine the condition of the economy. HUD uses the estimates to develop and evaluate housing programs. Manufacturers use estimates to plan production schedules and establish market shares. Insurance companies use estimates to adjust rates and establish replacement costs. Financial institutions use data to estimate mortgage demand.</p>	No, only national or regional statistics.	N/A	No

Survey of Income and Program Participation (SIPP)	No	SIPP collects data and measures change for many topics including: economic well-being, family dynamics, education, assets, health insurance, childcare, and food security. SIPP is a household-based survey designed as a continuous series of national panels. Each panel features a nationally representative sample interviewed over a multi-year period lasting approximately four years. SIPP is a source of data for a variety of topics and provides for the integration of information for separate topics to form a single, unified database. This allows for the examination of the interaction between tax, transfer, and other government and private policies. Government policy formulators depend heavily upon SIPP for information on the distribution of income and the success of government assistance programs. SIPP data provide the most extensive information available on how the nation's economic well-being changes over time. The 2014 SIPP Panel began in February 2014 with a sample of approximately 53,000 households based on the 2010 decennial census. Each household is interviewed four times.	Yes, although SIPP is primarily a national product, since the sample is usually too small for most states.	No	No
Survey of Market Absorption of New Multifamily Units (SOMA)	HUD	SOMA, sponsored by HUD, uses the Census Bureau's Survey of Construction (SOC) as its sampling base. Each month, a sample of residential buildings containing five or more units is selected for SOMA. Data are collected each month by the 12 Regional Offices of the Census Bureau. Interviews are conducted with the building manager, rental/sales agent, owner or builder.	No, only national or regional statistics.	N/A	No
Survey of Program Dynamics (SPD)	No	The Survey of Program Dynamics is a longitudinal, demographic survey designed to collect data on the economic, household, and social characteristics of a nationally representative sample of the U.S. population over time.	No	N/A	No
Telephone Point of Purchase Survey (TPOPS)	BLS	Collects data on where Americans are spending their money. The results of the TPOPS are used in the calculation of the Consumer Price Index (CPI). Participation in the TPOPS is based on random sampling. PR is not considered as part of the CPI calculation.	No	N/A	No
Value of Construction Put in Place Survey (VIP)	No	Provides monthly estimates of the total dollar value of construction work done in the United States (the 50 states and DC). Covers construction work done each month on new structures or improvements to existing structures for private and public sectors (in the 50 states and DC).	Yes	No	N/A

CAN LABOR REGULATION HINDER ECONOMIC PERFORMANCE?  
EVIDENCE FROM INDIA<sup>1</sup>

TIMOTHY BESLEY AND ROBIN BURGESS

This paper investigates whether the industrial relations climate in Indian states has affected the pattern of manufacturing growth in the period 1958-92. We show that states which amended the Industrial Disputes Act in a pro-worker direction experienced lowered output, employment, investment and productivity in registered or formal manufacturing. In contrast, output in unregistered or informal manufacturing increased. Regulating in a pro-worker direction was also associated with increases in urban poverty. This suggests that attempts to redress the balance of power between capital and labor can end up hurting the poor.

I. INTRODUCTION

One of the key challenges of development economics is to identify policies that harm or hinder growth, along with an assessment of their effectiveness in poverty reduction. Traditional views of the growth process put development of manufacturing at centre stage in the structural change accompanying economic development.<sup>2</sup> A casual look at the performance of some of the more successful Asian economies after 1960 adds credence to this view. For example, between 1960 and 1995, manufacturing as a share of GDP grew from 9 percent to 24 percent of GDP in Indonesia, 8 percent to 26 percent in Malaysia and 12.5 percent to 28 percent in Thailand.<sup>3</sup> All of these countries

Berta Esteve-Volart, Shira Klien, Silvia Pezzini, Marit Rehavi, Pataporn Sukontamarn and Kamakshya Trivedi provided excellent research assistance. The first draft of the paper was written while Robin Burgess was visiting the Massachusetts Institute of Technology which he wishes to thank for support and encouragement. We thank STICERD for financial support.

<sup>2</sup>See, for example, Kaldor [1967] for an early forceful statement of this view.

<sup>3</sup>Figures on manufacturing shares come from various issues of the World Development Indicators, World Bank, Washington D.C.

had strong overall growth performances and saw significant falls in absolute poverty.

In contrast, the Indian economy did not experience a significant expansion of manufacturing as a share of national income. Manufacturing output constituted 13 percent of GDP in 1960 (ahead of the countries listed above) but grew to only 18 percent of GDP by 1995. India's overall growth over this period was also relatively modest and it did not enjoy declines in absolute poverty on a scale witnessed elsewhere in Asia. While this pattern reflects a complex array of phenomena, a key issue is whether specific policy choices can be shown to have played a role.

This paper studies the role of labor market regulation in explaining manufacturing performance in Indian states between 1958 and 1992. Such regulation is frequently cited in explanations of India's poor growth performance over this period.<sup>4</sup> The charge is that granting excessive bargaining power to organized labor blunted investment incentives and gave India a generally unfavorable business climate. Our data on labor regulation come from looking at state amendments to the Industrial Disputes Act of 1947. While the act was passed at the central level, state governments were given the right to amend it under the Indian Constitution. The emphasis on central planning in India meant that state governments have had limited influence on industrial policy outside the area of industrial relations. We read the text of each amendment (113 in all) and classified each as pro-worker, pro-employer or neutral. This gave a sense of whether workers or employers benefited or whether the legislation had no appreciable impact on either group. Regulation applies to a specific sector – formal manufacturing – smaller firms in informal manufacturing are not covered.

Between 1958 and 1992 registered manufacturing output per capita grew by 3.3 percent per annum in India as a whole. This, however, masks significant variations across states. For example, West Bengal, which had the highest level of registered manufacturing output per capita at the beginning of the period, had fallen to seventh in 1992 – an average decline of 1.5 percent per annum. West Bengal also had the largest body of pro-worker labor regulation over the period. Its performance contrasts with Andhra Pradesh which grew at nearly 6 percent per year over the same period but which enacted pro-employer labor regulation.

We develop an econometric analysis of whether regulation can account for

---

<sup>4</sup>See, for example, Stern [2001] and Sachs, Varshney, and Bajpai, [1999].

the cross-state pattern of manufacturing performance over time. Our results show that pro-worker labor regulation resulted in lower output, employment, investment, and productivity in the formal manufacturing sector. Output in the informal sector increased. We also find that pro-worker labor regulation is also associated with increases in urban poverty.

The paper illuminates long-standing debates about the role of the state in promoting or hindering economic development. While there is now an abundance of cross-country evidence on determinants of growth, relatively little of this identifies robust relationships with policy regimes [see Barro, 1997]. Papers by Hall and Jones [1999] and Acemoglu, Johnson and Robinson [2001] do suggest that the quality of government institutions matter for economic performance. Looking at policies directly is, however, notoriously difficult given that the details of government intervention differ across countries. Djankov, La Porta, Lopez-de-Silanes, and Shleifer [2002] looks at regulations governing the starting of businesses in a cross-section of 85 countries. They find that countries with higher regulation of entry have less impressive performance across an array of social, political and economic indicators.<sup>5</sup> They find, in particular that greater regulation expands the size of the unofficial economy. They argue that this is in line with a public choice view of regulation as being put in place by officials or insiders intent on extracting rents (see, for example, Stigler [1971], De Soto [1989], and Shleifer and Vishny, [1998]).

Botero, Djankov, La Porta, Lopez-de-Silanes and Shliefer, [2003] code labor regulations in 85 countries, finding that heavier regulation of labor is associated with a larger unofficial economy, lower labor force participation and higher unemployment. Labor regulations are often cited as a determinant of economic performance in OECD countries [see Freeman, 1988; Blanchard, 2000; Nickell and Layard, 2000]. Higher unemployment in Europe vis a vis North America, for example, is often attributed to more ‘rigid’ labor institutions in the former [Nickell, 1997]. For European countries, Nickell and Layard [2000], argue that, labor market institutions such as unions and social security systems are important drivers of economic performance with strict labor market regulations, employment protection and minimum wages playing a lesser role. Limited institutional change and the difficulty of controlling for other policies and conditions, however, hinders identification. A number of studies interact labor institutions with observable shocks [Blanchard and Wolfers, 1999] or technological change [Card, Kramarz and Lemieux, 1999]

---

<sup>5</sup>India is close to average in this dimension – it is ranked above Indonesia and Japan.

to explore dynamic effects.

Here, we utilize both time and cross-section variation in labor regulation. The relatively long time period (35 years) and the fact that so much of the policy environment is common to the Indian states makes it an ideal testing ground for the effects of regulation on economic performance and welfare. It adds to a growing body of sub-national evidence that labor regulation affects economic performance. For example, Holmes [1998] uses comparisons across U.S. state borders to show that states which enacted pro-business right-to-work laws saw increases in manufacturing activity. Bertrand and Kramarz [2002] use time and regional variation in zoning board approvals to look at how these entry regulations affected employment growth in the French retail industry. Evidence from a variety of studies on Latin America also suggest the importance of labor regulation (see the collection of studies in Heckman and Pages [2003]).

The remainder of the paper is organized as follows. In section II we examine how economic performance has varied across different states, trace the evolution of labor market regulation in India, detail how we capture the direction of regulatory change and set out theoretical predictions on the impact of regulatory change on manufacturing performance. Section III contains the empirical analysis of the effect of labor regulation on manufacturing performance. Section IV turns to the welfare consequences of regulation in terms of poverty reduction and section V concludes.

## II. BACKGROUND

Table 1 contains the descriptive statistics for the main variables that we use in our analysis. Manufacturing is comprised of two sub-sectors – an unregistered (informal) sector of small firms and a registered (formal) sector of larger firms.<sup>6</sup> During the period of our data, the latter makes up about 9 percent of state output and the former 5 percent. Firms in the registered sector are covered by the Industrial Disputes Act and are included in the Annual Survey of Industries. This provides information on output, employment, wages, investment and productivity at the state level. Firms in the unregistered sector are not covered by labor regulations and are surveyed periodically in National Sample Surveys. Figure 1 shows how registered

---

<sup>6</sup>Specifically, firms are required to register if either (i) they have more than ten employees and electric power or (ii) they have more than twenty employees and do not use electric power.

manufacturing output varies across states. Some states: Andhra Pradesh, Gujarat, Karnataka, Tamil Nadu and Maharashtra show striking growth, while states like Assam, Jammu and Kashmir and West Bengal stagnate (albeit from very different base levels). These patterns are similar if we look at employment.

A great deal of industrial regulation in India has been central. The centerpiece of the planning regime was the Industries (Regulation and Development) Act of 1951 which states that “it is expedient in the public interest that the Union should take under its control the industries in First Schedule” (this lists all the key manufacturing industries at that date). There have been no formal amendments to this act at the state level (see Malik, 1997). We therefore have a situation where industries in different states of India are subject to a common set of industrial policies except in the area of industrial relations. Entry regulation, via licensing and other instruments, for example, is completely controlled by central government.

There has been much concern about the impact of industrial licensing and the use of tariff and non-tariff barriers. It is often suggested that this has led Indian manufacturing to perform poorly relative to other countries (see Singh [1964], Bhagwati and Desai [1970] and Bhagwati and Srinivasan [1975]). In particular, relative to countries in East Asia which experienced rapid manufacturing growth (World Bank, 1993; Bhagwati, 1998). But it is not possible to relate its impact to the patterns of economic development found in Figure 1.

Increasing attention is being paid to the spatial pattern of industrial development in India. A recent survey of about one thousand manufacturing establishments drawn from ten Indian states by Dollar, Iarossi and Mengitsae [2001] suggests that productivity is forty-four percent lower in states judged by managers to have poor business climates. Labor regulation is often singled out as an important element of business climate. Dollar et al [2001] found that managers would be willing to lay-off 16-17 percent of their work force if there was greater labor market flexibility and that this measure of the cost of labor regulation had a significant negative impact on firm level productivity.

## II.A *Labor Regulation*

India is a federal democracy and under the Indian Constitution of 1949 industrial relations is a concurrent subject. This implies that central and state governments have joint jurisdiction over labor regulation legislation. The key piece of central legislation is the Industrial Disputes Act of 1947

which sets out the conciliation, arbitration and adjudication procedures to be followed in the case of an industrial dispute. The Act was designed to offer workers in the organized sector some protection against exploitation by employers. The Act is comprised of seven chapters and forty sections, specifying the powers of government, courts and tribunals, unions and workers and the exact procedures that have to be followed in resolving industrial disputes.<sup>7</sup> It has been extensively amended by state governments during the post-Independence period. It is these amendments that we use to study the impact of labor market regulation on manufacturing performance and poverty.

We code legislation based on our reading of all state level amendments to the Industrial Disputes Act of 1947 from Malik [1997]. There were 113 such amendments since the Act was passed. Thus although all states have the same starting point, they diverged from one another over time. Each amendment is coded as being either neutral, pro-worker or pro-employer. While this method of classification required a number of judgement calls, we found surprisingly few cases of uncertainty.<sup>8</sup> For the purposes of quantitative analysis, we coded each pro-worker amendment as a one, each neutral amendment as a zero, and each pro-employer amendment as a minus one.

It is useful to give a couple of examples of this procedure. A sample pro-employer reform is from Andhra Pradesh in 1987. Our synopsis is:

“If in the opinion of the state government it is necessary or expedient for securing the public safety or the maintenance of public order or services or supplies essential to the life of the community or for maintaining employment or industrial peace in the industrial establishment it may issue an order which (i) requires employers and workers to observe the terms and conditions of an order and (ii) prohibits strikes and lockouts in connection with any industrial dispute.”

This amendment gets a code of minus one in our data. A sample pro-worker

---

<sup>7</sup>The seven chapters cover: (I) definitions; (II) authorities under this Act; (III) reference of disputes to Boards, Courts or Tribunals; (IV) procedures, powers and duties of authorities; (V) strikes and lockouts, lay-off and retrenchment, unfair labour practices; (VI) penalties and (VII) miscellaneous [see Malik, 1997].

<sup>8</sup>In each case, we based this on two independent assessments. Summaries of all amendments and their coding is available at <http://econ.lse.ac.uk/staff/rburgess/wp>.

reform is from West Bengal in 1980 where our synopsis is:

“The limit of 45 days for workers receiving 50% of their wages upon being laid off (if they worked for more than a year) is removed.”

This gets coded as one in our data. Having obtained the direction of amendments in any given year, we cumulated the scores over time to give a quantitative picture of how the regulatory environment evolved over time. This is our basic regulatory measure used below.<sup>9</sup>

This method classifies states as either “treatment” or “control” states. The latter are states that do not experience any amendment activity in a pro-worker or pro-employer direction over the 1958-1992 period. There are six of these: Assam, Bihar, Haryana, Jammu and Kashmir, Punjab and Uttar Pradesh. Among those that have passed amendments, our method classifies six states Andhra Pradesh, Karnataka, Kerala, Madhya Pradesh, Rajasthan and Tamil Nadu as “pro-employer”. This leaves four “pro-worker” states: Gujarat, Maharashtra, Orissa and West Bengal. Figure 2 graphs the history of regulatory change across states over the period in question. For the most part, changes are monotonic although some states do move in different directions. We have both pro-worker and pro-employer states among the fast growers.

Pro-worker states on average had high per capita registered manufacturing output in 1960 relative to control states and pro-employer states. However by 1990, there is no statistically significant difference between pro-worker and pro-employer states. Moreover, registered manufacturing output in the pro-employer states has overtaken that in the control states. This pattern is less pronounced when looking at overall output per capita. Other state characteristics such as total taxes per capita, development expenditure per capita, installed electricity per capita and literacy show no significant difference between treatment and control states.

---

<sup>9</sup>In years in which there were multiple amendments, we use an indicator of the general direction of change. So, for example, if there were four pro-worker amendments in a given state and year, we would only code this as plus one rather than plus four. Coding in this manner gives us a total of nineteen changes in our period (see Figure 2). In an Appendix Table we describe the individual state level amendments which lie behind each of these changes. These take a variety of forms covering limits on the ability to strike, changing the rules relating to layoff, retrenchment and closure and giving workers or employers greater power in the procedures for resolving industrial disputes.

Before considering the impact of labor regulation on economic outcomes, we show that the regulation measure is related to the industrial relations climate in a state as measured by work days lost to strikes and lockouts in the registered manufacturing sector.<sup>10</sup> This may be a key signal to potential investors. Table 2 shows that labor regulation is strongly positively correlated with work days lost to strikes and lockouts per worker.<sup>11</sup> Columns (2) and (4) show this finding to be robust to including state specific time trends. Thus, regulating in a pro-worker direction appears to be associated with greater disruption of production. This validates our measure as a representation of the industrial relations climate.

## II.B Theoretical Considerations

The defining difference between registered and unregistered firms is scale, with labor regulations affecting only registered firms. It is reasonable to suppose that all firms operate in a common set of factor markets whose prices they treat as parametric. For simplicity, suppose that firms all produce a common manufactured good. There are then two main routes via which labor regulation affects economic performance – a *relative price effect* and an *expropriation effect*. While intellectually distinct, they have similar implications for what we expect to find in the data.

The relative price effect is relevant if the effect of labor regulation is to raise the (fixed or marginal) cost of employing laborers. Labor regulation will typically create adjustment costs in hiring and firing labor and in making adjustments in the organization of production. We would expect firms in the registered sector to substitute away from labor (reducing employment) towards other labor saving inputs (including capital if labor and capital are substitutes). Regulation also lowers the firm’s optimal output level since it

---

<sup>10</sup>Strikes and lockouts are both important sources of lost working time. There are twice as many work days lost to strikes than to lockouts. There is pronounced variation across states and time – West Bengal, for example, loses twenty five times as many work days to strikes per capita relative to Assam.

<sup>11</sup>We run panel data regressions of the form:

$$y_{st} = \alpha_s + \beta_t + \mu r_{st-1} + \varepsilon_{st}$$

where  $y_{st}$  is work days lost to strikes and lockouts per worker in the registered manufacturing sector,  $r_{st}$  is the regulatory measure,  $\alpha_s$  is a state fixed effect and  $\beta_t$  is a year effect. We cluster our standard errors by state to deal with concerns about serial correlation.

raises the marginal cost of production. We would also expect regulation to affect the decision to register. In states where regulations raise labor costs, firms will (other things being equal) resist becoming registered by remaining small. Thus, we would expect to find fewer registered firms along with a higher level of production in the unregistered sector in states that legislate in a pro-worker direction.

The expropriation effect refers to the dynamic implications of labor regulation. By increasing the bargaining power of workers, labor regulation can increase the importance of hold-up problems in investment.<sup>12</sup> Suppose that firm's invest in anticipation of earning a particular return may face a problem if workers can expropriate part of that return once the capital is sunk. This will serve to discourage investment, even if labor and capital are substitutes. This has similar predictions in terms of output, employment, output and the decision to register as the relative price effect. However, it strengthens the presumption that capital stocks will also be lower. This effect shows why pro-worker labor regulation is similar to insecure property rights for owners of capital as their sunk investments are subject to worker expropriation.

Whether workers benefit from labor regulation is not clear cut. If labor costs rise because firms put in more worker friendly work practices, then it will depend on how these are paid for in terms of lower wages or lower employment. There may also be differential effects on insiders and outsiders. If there is a hold-up problem, then workers should realize that if they have too much bargaining power, they will reduce investment to their own detriment (especially if labor and capital are complements). Whether wages rise or fall is also not clear-cut.

### III. METHOD AND RESULTS

Our econometric analysis is based on panel data regressions of the form:

$$y_{st} = \alpha_s + \beta_t + \mu r_{st-1} + \xi x_{st} + \varepsilon_{st}$$

where  $y_{st}$  is a (logged) outcome variable in state  $s$  at time  $t$ ,  $r_{st}$  is the regulatory measure (which we lag one period to capture the gap between enactment

---

<sup>12</sup>Grout [1984] developed one of the first models along these lines. Caballero and Hamour [1998] draw out macro-economic implications.

and implementation)<sup>13</sup>,  $x_{st}$  are other exogenous variables,  $\alpha_s$  is a state fixed effect and  $\beta_t$  is a year fixed effect. We cluster our standard errors by state to deal with concerns with serial correlation (Bertrand, Duflo and Mullainathan, [2002]).<sup>14</sup>

The state fixed effect captures state-specific factors such as culture and geography. The year effects capture common shocks such as central government amendments to the Industrial Disputes Act which took place in 1976 and 1982 (see Fallon [1987] and Fallon and Lucas [1993]) as well as other centrally implemented policies.

### III.A *Basic Results*

Table 3 looks at measures of output per capita and their link to labor regulation. The left hand side variable in column (1) is total state output per capita which does not appear to be correlated with the labor regulation regime. This is reasonable since labor regulation is sector specific and registered manufacturing represents a fairly small part of the Indian economy. Above all, this suggests that labor regulation is not simply a proxy for generally poor government policy. Column (2) looks at agricultural output. A negative effect here would also suggest that our labor regulation is really proxying for other policies. In fact, there is a weak positive effect suggesting that discouraging manufacturing may encourage agricultural production. In contrast, non-agricultural output – which includes manufacturing – is negatively correlated with labor regulation (column (3)). Column (4) shows that there no effect on output in the construction sector, another sector where labor regulation is not applied.<sup>15</sup>

Turning to manufacturing, column (5) shows that the point estimate becomes larger and more significant when focusing on total manufacturing output. Breaking this into registered and unregistered sectors as in columns (6) and (7) of Table 3 provides further confirmation that the effect at work is specific to registered manufacturing. There is now a larger and more significant negative effect on registered manufacturing in column (6). Moreover, for unregistered manufacturing in column (7), we get the opposite sign –

---

<sup>13</sup>Our results are robust to imposing different lags. Our readings of the literature suggests that amendments come into force roughly one year after they are passed.

<sup>14</sup>We conducted some stationarity tests for panel data of the kind suggested by Madalla and Wu [1999]. These suggested no difficulty in assuming stationarity.

<sup>15</sup>Over our period construction accounts for 5 percent of total state output and 10 percent of non-agricultural output.

high levels of pro-worker labor regulation have a positive impact on output in this sector.<sup>16</sup> Thus labor regulation seems to deter formal registration, encouraging firms to remain in the informal sector.

These results make sense. Labor regulation is affecting only that sector where we should expect to see an effect. Since labor regulations are the main regulatory instrument in registered manufacturing under state control, this finding is compelling. Our next tasks are to check the robustness of these findings to a number of other specifications and to expand the set of registered manufacturing performance measures beyond just output.

Table 4 assesses the robustness of the finding that registered manufacturing responds negatively to pro-worker labor regulation. Column (1) replicates the basic result from Table 3. In column (2) we add a number of controls. These are the log of real development expenditure per capita which includes spending on health, education, infrastructure and administration. This helps crudely to measure differences in human capital and infrastructure due to government activities. We also include the log of installed electrical capacity per capita, measured in kilowatts, to capture the capacity of states to generate electricity. It may also be a reasonable proxy for the general state of infrastructure and is positively associated with registered manufacturing output. Finally, the log of the state population is also included as a crude measure of changing labor market conditions within a state. Column (2) shows that the coefficient on labor regulation remains negative and significant when we include these controls.

While these results help to deal with the concern that labor regulation is a proxy for other state level policies, it is possible that some aspects of the policy environment are difficult to measure. As a further robustness check, we therefore add in controls for the political complexion of states on the grounds that policies towards the registered manufacturing sector are likely to be correlated with political outcomes. To this end, we assemble a picture of each state's "political history" as measured by the number of years during our data period that particular political groupings have held a majority of the seats in the state legislature. The relevant groupings for this exercise are: the Congress party, the Janata parties, hard left parties and regional parties. The results are in column (3). They show that greater hard left control of the state legislature depresses growth in registered manufacturing. The

---

<sup>16</sup>The idea that firms migrate to the informal sector to escape regulation is widespread – see, for example, Schneider and Enste [2000].

coefficient on labor regulation does, however, remain negative and significant, even though it is smaller in absolute size. The result is consistent with notion that there are anti-business policies which hard left governments introduce. Nonetheless, the effect of labor regulation remains.

In column (4), we add state specific time trends. In this case, the identification of the effects of labor regulations comes from whether such law changes lead to deviations from pre-existing state specific trends. The effect of labor regulation is no longer apparent. Thus, states with similar patterns of labor regulation also have similar long-term trends. Labor regulation appears therefore to be driving differences in these trends. But this does raise the issue of whether it is possible to separate out effects of labor regulations *per se* from impacts due to the climate of labor relations such as union power and labor/management hostility which manifest themselves in the trend growth rate. We return to this issue below.

Column (5) addresses the sensitivity of the results to the inclusion of West Bengal. This state is an important case for our analysis since it passed the largest number of pro-worker amendments and has had a declining manufacturing base. However, as column (5) shows, the results hold up even if we exclude it from the regression.<sup>17</sup> In column (6) we show that the result on unregistered manufacturing is robust to including our control variables and excluding West Bengal.

Table 5 looks at the effect for a variety of other performance measures in registered manufacturing. We report this for a specification that includes the full set of controls. In columns (1) and (2), we look at two measures of manufacturing employment. The first, reported in column (1) is the log of total employees taken from the Annual Survey of Industries. This covers both production workers and those in supervisory or managerial positions. We find states with more pro-worker legislation have lower levels of employment in registered manufacturing. This parallels our findings for output.<sup>18</sup> Column (2) examines daily employment defined as total worker attendances over a year divided by the total number of days worked by the factory. This measure which, captures the intensity of labor usage, is based

---

<sup>17</sup>We carried out further checks by excluding each of the states and in all cases the coefficient on labor regulation remained negative and significant.

<sup>18</sup>It is also consistent with Fallon [1987] and Fallon and Lucas [1993] who found that strengthening job security regulations via the 1976 and 1982 central government amendments to the Industrial Disputes Act was associated with a reduction in labor demand in firms covered by the regulation but not in small firms uncovered by job security regulations.

on returns submitted by registered manufacturing firms and comes from a separate data source, the Indian Labor Yearbook.<sup>19</sup> Here again we find a negative and significant impact of labor regulation. Comparing columns (1) and (2) suggests that there is greater adjustment in the intensity of labor usage as opposed to in aggregate employment levels which may be connected to constraints on firing workers and closing down firms [Fallon and Lucas, 1993].

Column (3) of Table 5 considers how earnings per worker are affected by labor regulation. The measure is obtained by dividing the total factory wage bill (which includes all monetary payments to workers) by the number of workers. We find that there is no significant effect of regulation on payments to workers.<sup>20</sup> This lines up with the fact that theory does not give any clear-cut predictions for wages. The bottom line is that workers do not appear to be gaining from pro-worker amendments.

In column (4) of Table 5, we examine fixed capital formation. Labor regulations that increase worker bargaining power are likely to reduce capital formation. The coefficient on labor regulation is consistent with this story. Column (5) shows that the number of registered manufacturing factories is negatively related to pro-worker labor regulation.<sup>21</sup> Column (6) looks at firm firm efficiency in the form of value added per employee. Value added in firms is lower in which there is more labor regulation. This is consistent with an expropriation effect whereby blunting investment incentives leads to labor regulations being associated with lower productivity in the registered manufacturing sector.<sup>22</sup>

To gauge the economic significance of these findings we look at two extreme cases: Andhra Pradesh as a pro-employer state and West Bengal as a pro-worker state. The coefficients from the basic specifications in Tables 4 and 5 imply that without their pro-employer reforms, Andhra Pradesh would

---

<sup>19</sup>As they are based on submissions these figures are likely to be less reliable those based on the Annual Survey of Industries. They nonetheless serve as a useful robustness check.

<sup>20</sup>In an earlier version of the, we found that is also true for a number of different measures of earnings drawn from both the Annual Survey of Industries and the Indian Labor Yearbook [see Besley and Burgess, 2002].

<sup>21</sup>This variable captures the net flow of firms in the registered manufacturing sector. It shows that the number of firms is significantly lower in states with more pro-worker regulation, suggesting that pro-worker regulation is either acting as a deterrent to new firms or to firms dying at a faster rate.

<sup>22</sup>The results in Table 5 are robust to excluding West Bengal. However, in common with the output results, they are not robust to including state specific time trends.

have registering manufacturing output which was 72 percent of its actual 1990 level and manufacturing employment that was 73 percent of its 1990 level. Had West Bengal not passed any pro-worker amendments it would have enjoyed a registered manufacturing output that was 24 percent higher than its 1990 level and employment that was 23 percent higher.<sup>23</sup> Thus, the implied economic magnitudes are sizeable.

Collectively these results paint a consistent picture.<sup>24</sup> Across the board, our labor regulation measure is correlated with poor economic performance in the registered manufacturing sector. It also leads to a larger informal sector.

### III.B *Endogeneity*

A remaining concern is that states with larger vested interests in manufacturing at the beginning of the period may have experienced greater pressure to pass pro-worker amendments and may, as a consequence, have experienced

---

<sup>23</sup>Though inclusion of the full set of political and economic controls does reduce the magnitudes of these effects they remain economically important.

<sup>24</sup>As a further control for omitted variables, we have collected information on the efficiency of state high courts in India as measured by annual pendency rates. The pendency rate is constructed by adding the number of cases pending at the beginning of the year to cases filed in the year and dividing this by cases resolved during the year. This measure, which is available only for a shorter time period, 1971 - 1996, may be a determinant of the property rights regime in force in the state. In contrast with our labor regulation variable, it has a significantly *negative* impact on log agricultural output per capita (the coefficient is -0.105 with a robust t-statistic, adjusted for clustering on state, of 2.57). It also has significant and negative association with non-agricultural output as a whole. Within manufacturing it is negatively correlated with the log of unregistered manufacturing output per capita (the coefficient is -0.458 with a robust t-statistic, adjusted for clustering on state, of 1.69) – the opposite sign from labor regulation variable (the coefficient is 0.098 with a robust t-statistic, adjusted for clustering on state, of 2.35) Thus, court inefficiency is correlated with lower informal sector manufacturing. Unlike labor regulation his efficiency measure is not significantly negatively correlated with the log of output per capita in registered manufacturing. The picture that emerges therefore is one where court efficiency adversely affects economic activity in a wide range of sectors, in particular in the large informal sectors where problems of property rights and law and contract enforcement may be acute. In contrast, labor regulations only negatively affect the sector to which they apply and, in contrast, encourage economic activity in unregistered manufacturing and agriculture. These results help to increase our confidence that our amendments measure is picking up the impact of labor regulation as opposed to of other anti-business policies. The question of how courts work in India and affect economic performance is an important issue for further research.

slower growth. Indeed, theoretical arguments along these lines have been developed in the political economy of development literature. For example Krusell and Rios-Rull (1996) model the idea that political insiders can see development as a threat to their rents and hence lobby for protection. In an Indian context, workers would lobby for stricter labor regulation as a means of extracting a greater share of the surplus from existing investments even though this may deter future investment. Thus, the negative correlation between output and performance is consistent with reverse causation. We now develop two ways of addressing this concern empirically.

As our measure of the extent of vested interests, we take the average level of union membership (union members divided by population) before 1977.<sup>25</sup> We first use these data to match states that experience labor market reforms (pro-worker or pro-employer) with control states based on the level of unionization.<sup>26</sup> We then regress labor regulation on the difference between registered manufacturing in a ‘treatment’ state and that in its matched ‘control’ state while also including match dummies in the regression.

The results are in columns (1) - (3) of Table 6. They confirm the effects on registered and unregistered manufacturing output per capita and employment in registered manufacturing per capita that we have found throughout. They add credibility to the findings since they guard against the concern that there is something in the initial condition, rather than the subsequent policy experience, which is driving subsequent performance.

An extension of this idea can also yield an instrumental variable for labor regulation. Looking at Figure 2, it is striking that most of the labor regulation changes take place after 1977. This is no-coincidence. Following Prime Minister Indira Gandhi’s declaration of a state of emergency (suspending democratic institutions), the political power of her party (Congress) was significantly and permanently diminished.<sup>27</sup> There were a number of switches in political control with Congress losing its majority in half of our states

---

<sup>25</sup> The data on union membership are patchy. For example there are no usable data for Jammu and Kashmir. Moreover, there are often gaps in the series. We choose the pre-1977 average to get a better sense of the level of unionization.

<sup>26</sup>See the Data Appendix for details on state matches. We also matched based on initial registered manufacturing output per capita, obtaining similar results.

<sup>27</sup>Declaration of a state of emergency was a response to calls for her resignation after she was found guilty of using illegal practices during the prior election campaign. Between 1975, when emergency was declared, and 1978, when fresh elections were called, the share of congress votes in state assemblies dropped from 60% to 38%.

between 1975 and 1978. The most notable example was the left front which gained a majority in West Bengal in 1977 and has remained the majority coalition ever since. The 1947 Industrial Disputes Act represented a piece of Congress legislation which was largely kept intact pre-1977 by Congress dominated state governments. Post-1977 state deviations are likely in part to be a result of changes in political control. And the direction that post-1977 amendments took would depend, in part, on the importance of the initial vested interests (as proxied by union membership). This suggests that the union membership variable interacted with a dummy which equals one after 1977 may pick up the time path of labor regulation.

In addition to union membership, we also use historical patterns of land tenure to develop a further instrument.<sup>28</sup> The main difference is between those areas in India where land revenue was collected through landlords or not. Banerjee and Iyer (2002) show that these measures have an impact on contemporary patterns of development, particularly agricultural productivity and public good provision. Our motivation for using this variable is the possibility that it is correlated with contemporary patterns of political development. In confirmation of this, we find that areas dominated by non-landlord based revenue collection have larger concentrations of regional parties today, i.e. those that do not have a large role in other states or in the national legislature. In many cases, these parties were the main competitor to the Congress party and hence benefitted politically from the state of emergency. Hence, our instrument interacts the fraction of districts in each state that had non-landlord based revenue collection systems with a dummy variable which equals one after 1977 to mark the persistent shift in political control after the state of emergency.

Column (7) of Table 6 confirms that both of our instruments are correlated with labor regulation (F-statistic=7.46). The union variable is positively correlated with labor regulation while the variable based on the proportion of districts under the non-landlord based agricultural tax system is negatively correlated with labor regulation.<sup>29</sup> In columns (4), (5) and (6), we report two-stage least squares estimates of the effect of labor regulation

---

<sup>28</sup>We are grateful to Abhijit Banerjee and Lakshmi Iyer for providing this data. For each modern state, the variable that we use is the mean number of constituent districts in British India which had non-landlord based land revenue systems. Its construction is described in detail in the Data Appendix.

<sup>29</sup>As we discussed above, the second of these is explained by the correlation between this variable and regional party development.

on output and employment using these two variables as instruments. Our results are robust to this instrumentation. Moreover, the Sargan test of over-identification passes comfortably.<sup>30</sup>

The effects in the instrumental variables case are uniformly larger in absolute size. This suggests that, if anything biases could be due to high levels of economic performance generating demand for protecting workers.<sup>31</sup> Overall, these results increase our confidence that poor performance in registered manufacturing was a consequence rather than a cause of labor regulations.

### III.C *Disaggregated Evidence*

The evidence presented so far aggregates all registered manufacturing industries together. But Indian states have quite different manufacturing bases. Hence, there might be a suspicion that patterns of specialization affect the direction of regulation in ways that could bias our results. For example, early industrializing states might specialize in slow growing labor intensive industries which spawn stronger vested interests, thereby inducing a negative correlation between pro-worker regulations and manufacturing performance.

In response to such concerns, we present results on disaggregated data which look at the impact of labor regulation at the 3-digit industry level for the period 1980-97.<sup>32</sup> In line with the analysis above, we investigate the link between performance and labor regulation by running panel regressions of the form:

---

<sup>30</sup>The results are not robust to including state specific time trends. Thus we cannot rule out the possibility that the *trends* in manufacturing output prior to our data period were important in the subsequent pattern of manufacturing development.

<sup>31</sup>This is consistent with our efforts to investigate whether changes in labor regulations were timed around deviations in manufacturing output changes from their trend. We constructed a measure of “recessions” classified as periods in which output growth falls below trend for two consecutive years. No clear pattern emerged. Recessions actually accompanied pro-firm regulatory changes in five of our eighteen reforms (Andhra Pradesh in 1968, Karnataka in 1988, Madhya Pradesh in 1982, Rajasthan in 1970 and Tamil Nadu in 1982). By contrast, it accompanied pro-worker changes in only three cases (Maharashtra in 1974, Orissa in 1983 and West Bengal in 1974).

<sup>32</sup>The data form an unbalanced panel. Our analysis retains state industries which remain in the panel for at least ten years and within these industries we restrict our attention to firms which employ more than a hundred workers to get around the problem of smaller firms being excluded from the sample to maintain confidentiality. Using this a definition we have total of 101 3-digit industries in our panel with an average of 68 in each state. The results we obtain are robust to using a balanced panel (i.e. only retaining state 3-digit industries which remain in the panel over the whole 1980-1997 period).

$$y_{ist} = \alpha_{is} + \beta_t + \delta_i t + \mu r_{st-1} + \varepsilon_{ist}$$

where  $y_{ist}$  is a (logged) 3-digit industry outcome variable,  $r_{st-1}$  is the labor regulation measure measured at the state level and lagged one period,  $\alpha_{is}$  is a state-industry fixed effect,  $\beta_t$  is a year effect,  $\delta_i$  is a dummy variable which is equal to one for industry  $i$  and  $t$  is a time trend. We cluster our standard errors by state-industry grouping to deal with concerns about serial correlation. Inclusion of the state-industry fixed effect allows us to control for unobserved, time-invariant factors which affect performance at the state 3-digit industry level. Thus, identification is now coming from within state-industry variation. The inclusion of 3-digit industry time trends in the regressions also helps to control for the possibility that industries experience different rates of technological change.

Column (1) in Table 7 confirms the basic result above showing that regulating in a pro-worker direction has a significant and negative impact on registered manufacturing output. Column (2) shows that the results for employment also mirror those for state level analysis – employment growth within 3-digit industries is lower in states which regulated in a pro-worker direction. Column (3) confirms our result on fixed capital – investment in fixed capital is lower in pro-worker versus pro-employer states. Moreover, the magnitude of the coefficients we observe in columns (1) – (3) of Table 7 is similar to those in Tables 4, 5 and 6. Column (4), which looks at the number of registered firms in a three digit industry, lines up with the investment effect in column (3) by suggesting that there is greater entry/lower exit in states that regulate in a pro-employer direction. Column (5) shows that regulating in a pro-worker direction is correlated with lower productivity at the 3-digit industry level as measured by value-added per employee.<sup>33</sup>

While available only for a shorter time period, these results are very similar to those found for the aggregate data for the period 1958-92. They allay any fears that our results are an artefact of patterns of specialization or technological change in registered manufacturing across Indian states.

#### IV. WELFARE CONSEQUENCES

---

<sup>33</sup>Although we are allowing for industry specific time trends, the results do not hold up with state specific trends.

We turn finally to the effect of labor regulation on poverty. This is important for a number of reasons, not least because it may give a sense of where the burden of the effects identified in the last section have been felt. To assess this, we use poverty data from Ozler, Datt and Ravallion [1996]. We focus on urban and rural headcounts which measure the percentage of the population below the Indian urban and rural poverty lines. The econometric specification we use is the same as for manufacturing performance.

We expect the direct effect on poverty to depend on the extent to which the earnings of the poor are derived from registered manufacturing. While we have no direct quantitative estimate of this, it is instructive to consider the correlation between poverty rates and different components of state output in India. To do so, we disaggregated state output into agricultural, registered manufacturing, unregistered manufacturing and “other” (non-agricultural/non-manufacturing).<sup>34</sup> We find that for urban poverty, the largest coefficient is on registered manufacturing and “other”.<sup>35</sup> Agricultural output and unregistered manufacturing are not significantly correlated with urban poverty. For rural poverty, there is a significant negative correlation between unregistered manufacturing and poverty and no significant correlation with registered manufacturing. These findings square with the fact that registered manufacturing firms are located mainly in urban areas whereas unregistered manufacturing firms are located in both rural and urban areas.

Given this pattern of correlations, our presumption is that pro-worker regulation is positively correlated with poverty in urban areas – with an effect operating through lowered registered manufacturing output and employment. There is no reason to expect a correlation with rural poverty. Table 8 shows that this is indeed the case. In column (1) we see that labor regulation has no effect on overall poverty. This lines up with our result for overall output. Regulating in a pro-worker direction is, however, associated with higher urban poverty (columns (2)). In column (3) we see that, in line with our expectations, there is no significant effect on rural poverty. This

---

<sup>34</sup>Specifically, we run

$$p_{st} = \alpha_s + \beta_t + \gamma y_{st} + \varepsilon_{st}$$

where  $y_{st}$  is a vector of disaggregated income measures and  $p_{st}$  is a poverty headcount measure.

<sup>35</sup>We cannot reject the hypothesis that the coefficients on these two output sources are equal.

is consistent with the majority of registered manufacturing firms being in urban locations. In column (4) we find that the results hold up when we add economic controls to our basic specification from column (2). The labor regulation variable continues to exert a significant positive influence on the urban headcount. It is interesting to note that Congress control and hard left control are associated with higher levels of urban poverty.

Column (5) adds state specific time trends. Once again, this wipes out the effect of labor regulation. This underlines the need to exercise caution in attributing the effects observed in columns (2) and (4) to labor regulations as opposed to interactions of underlying differences in the industrial relations climate with regulations.

In column (6) we see that the effects remain when we run the regression only for years when NSS surveys were carried out. This shows that the result in column (6) is not sensitive to interpolating poverty statistics between years. In column (7) we exclude West Bengal from the regression and continue to observe a positive and significant link between pro-worker labor regulation and urban poverty. The coefficient on labor regulation in urban headcount regressions remains highly stable across the full range of specifications (barring column (5)) in Table 8.<sup>36</sup>

The economic significance of these effects can be gauged by examining what urban poverty would have been in 1990 had states not passed pro-worker or pro-employer amendments using the coefficient from column (2) in Table 8. Our empirical model predicts that, without their pro-employer reforms, then Andhra Pradesh would have urban poverty that was 112 percent of its 1990 level. Similarly, had West Bengal not passed any pro-worker amendments it would have had urban poverty that was 11 percent lower in 1990. This comparison starkly brings out how the direction of regulatory change matters. According to our estimates, there would have been around 640 thousand more urban poor in Andhra Pradesh in 1990 and around 520 thousand less urban

---

<sup>36</sup>To check whether the coefficients in Table 8 are consistent with the entire effect on poverty reduction coming through the effect on registered manufacturing output, we regressed urban poverty on registered manufacturing. This yields a coefficient of -3.4. The size of the effect implied in Table 3 is 0.8 compared to a coefficient in Table 8 of 2.3. However, despite the apparently larger reduced form effect, these two estimates do lie within the 95% confidence interval for the compound effect of labor regulation. Nonetheless, the results are suggestive of the possibility of a direct effect of labor regulation on poverty beyond the effect operating through falls in registered manufacturing output. For example, regulations could make it easier for non-poor insiders to exclude poor outsiders from access to jobs in the registered sector.

poor in West Bengal had these states not amended the Industrial Disputes Act.<sup>37</sup>

These welfare results are striking. The battle cry of labor market regulation is often that pro-worker labor market policies redress the unfavorable balance of power between capital and labor, leading to a progressive effect on income distribution. We find no evidence of this here – indeed the distributional effects appear to have worked against the poor.

## V. CONCLUSIONS

This paper has examined the link between regulation and long-run development. The evidence amassed in the paper points to the direction of labor regulation as a key factor in the pattern of manufacturing development in India. Regulating in a pro-worker direction was associated with lower levels of investment, employment, productivity and output in registered manufacturing. It also increased informal sector activity.

The results leave little doubt that regulation of labor disputes in India has had quantitatively significant effects. In India, the hand of government has been at least as important as the invisible hand in determining resource allocation. This has provoked heated debate about which aspects of this role have constituted a brake on development. It is apparent that much of the reasoning behind labor regulation was wrong-headed and led to outcomes that were antithetical to their original objectives.

The paper finds little evidence that pro-worker labor market regulations have actually promoted the interests of labor and, more worryingly, that they have been a constraint on growth and poverty alleviation. Our results have not been able thus far to find any gainers except for the extent to which there may have been capital and labor flows across Indian states in response to policy disparities as they have developed. Our finding that regulating in a pro-worker direction was associated with increases in urban poverty are particularly striking as they suggest that attempts to redress the balance of power between capital and labor can end up hurting the poor.

The fact that our results are not robust to state specific time trends does raise the question of whether the effects that we are picking up are those due to labor regulations *per se* or the consequences of a poor climate of

---

<sup>37</sup>The urban population of Andhra Pradesh and West Bengal were 17.15 and 18.15 million respectively in 1990.

labor relations – union power and labor/management hostility – which affect the trend rate of growth within a state. This goes to interpretation of the finding. But either way, the analysis suggests that labor market institutions in India have had an important impact on manufacturing development.

The analysis reinforces the growing sentiment that government regulations in developing countries have not always promoted social welfare. The example that we have studied here is highly specific and it is clear that it cannot be used to promote a generalized pro- or anti-regulation stance. Future progress will likely rest on improving our knowledge of specific regulatory policies. Research involving particular country experiences will be an important component of this. Only then can the right balance between the helping and hindering hands of government be found.

#### DATA APPENDIX

The data used in the paper come from a wide variety of sources.<sup>38</sup> They cover the sixteen main Indian states listed in Figure 1 and refer mainly to the period 1958-1992. Haryana split from the state of Punjab in 1965. After this date on, we include separate observations for Punjab and Haryana. Variables expressed in real terms are deflated using the **Consumer Price Index for Agricultural Laborers** (CPIAL) and **Consumer Price Index for Industrial Workers** (CPIIW). These are drawn from a number of Government of India publications which include Indian Labor Handbook, the Indian Labor Journal, the Indian Labor Gazette and the Reserve Bank of India Report on Currency and Finance. Ozler, Datt and Ravallion [1996] have further corrected CPIAL and CPIIW to take account of inter-state cost of living differentials and have also adjusted CPIAL to take account of rising firewood prices. The reference period for the deflator is October 1973- March 1974. State **population** data used to express magnitudes in per capita terms and as a control comes from the 1951, 1961, 1971, 1981 and 1991 censuses [Census of India, Registrar General and Census Commissioner, Government of India] and has been interpolated between census years. Separate series are available for urban and rural areas.

---

<sup>38</sup>Our data sets builds on Ozler, Datt and Ravallion [1996] which collects published data on poverty, output, wages, price indices and population to construct a consistent panel data set on Indian states for the period 1958 to 1992. We are grateful to Martin Ravallion for providing us with this data and to Guarav Datt for answering various queries. To these data, we have added information on labor regulation, manufacturing performance, political representation, infrastructure and public finances of Indian states.

The **labor regulation** variable comes from state specific text amendments to the Industrial Disputes Act 1947 as reported in Malik [1997]. We decided to code each change in the following way: a 1 denotes a change that is pro-worker or anti-employer, a 0 denotes a change that we judged not to affect the bargaining power of either workers or employers and a  $-1$  denotes a change which we regard to be anti-worker or pro-employer. There were 113 state specific amendments coded in this manner. Where there was more than one amendment in a year we collapsed this information into a single directional measure. Thus reforms in the regulatory climate are restricted to taking a value of 1, 0,  $-1$  in any given state and year. To use these data, we then construct cumulated variables which map the entire history of each state beginning from 1947 – the date of enactment of the Industrial Disputes Act.

Data on **annual work days lost to strikes and lockouts** comes from various issues of the Indian Labor Yearbook, Labor Bureau, Ministry of Labor, Government of India. We divide this by number of workers employed from the Annual Survey of Industries data to get a per worker measure.

**State output** comes from Estimates of State Domestic Product published by Department of Statistics, Ministry of Planning, Government of India. Output variables are deflated and expressed in log per capita terms. The breakdown of total output into agricultural, non-agricultural and manufacturing output is done under the National Industrial Classification System (NIC) which conforms with the International Standard Industrial Classification System (ISIC). Within manufacturing – registered manufacturing is defined by the Factories Act of 1948 to refer to firms with ten or more employees with power or twenty or more employees without power. Unregistered manufacturing refers to firms below these cutoffs and the size of this sector is appraised by sample surveys carried out by the Department of Statistics.

Figures on **employees and workers** come from the Annual Survey of Industries, Central Statistical Office (Industrial Statistics Wing), Department of Statistics, Ministry of Planning and Programme Implementation, Government of India. Workers are defined as to include all persons employed directly or through any agency whether for wages or not and engaged in any manufacturing process or in any other kind of work incidental to or connected to the manufacturing process. Employees includes all workers and persons receiving wages and holding supervisory or managerial positions engaged in administrative office, store keeping section and welfare section, sales department as also those engaged in purchase of raw materials etc. or purchase of

fixed assets for the factory and watch and ward staff. **Daily employment** figures are from returns submitted from firms under the Factories Act of 1948 which have been analyzed and collated in the Indian Labor Yearbook, Labor Bureau, Ministry of Labor, Government of India. They are obtained by dividing total worker (defined as above) attendances in a year by the number of days worked by the factory.

**Earnings** are defined to include all remunerations capable of being expressed in monetary terms and also payable more or less regularly in each pay period to workers. It includes (a) direct wages and salary payments, (b) remuneration for period not worked, (c) bonuses and ex-gratia payments paid both at regular and at less frequent intervals. It excludes (a) lay off payments which are made from trust or other social funds set up expressly for this purpose, imputed value of the benefits in kind, (b) employer's contribution to the old age benefits and other social security charges, direct expenditure on maternity benefits and crèches and other group benefits, (c) travelling and other expenditure incurred for the business purpose, are re-imbrued by the employer are excluded. Earnings are expressed in terms of gross value i.e. before deduction for fines, damages, taxes, provident funds, employee's state insurance contribution etc. They come from the Annual Survey of Industries and are expressed in real per worker terms.

**Value-added** in the registered manufacturing sector is the increment to the value of goods and services that is contributed by the factory and is obtained by deducting the value of total inputs and depreciations from the value of output. The **number of factories** variable comes from the list maintained by the Chief Inspector of Factories in each state which is updated to take into account both deregistration of firms and new entrants. It thus captures the net flow of firms in the registered manufacturing sector. **Fixed capital** represents the depreciated value of fixed assets owned by the factory on the closing date of the accounting year. Fixed assets are those which have a normal productive life of more than one year. Fixed capital covers all types of assets new or used or own constructed, deployed for production, transportation, living or recreational activities, hospitals, schools etc for factory personnel. All these measures come from the Annual Survey of Industries.

Total **installed electrical capacity** of electrical generation plants is measured in thousand kilowatts and come from various issues of the Statistical Abstracts of India, Central Statistical Office, Department of Statistics, Ministry of Planning, Government of India. It is expressed in log per capita

terms. **Development expenditure** refers to state spending on economic services (agriculture, rural development, special area programs, irrigation and flood control, energy, industry and minerals, transport and communications, science, technology and environment) and social services (education, medical and public health, family welfare, water supply and sanitation, housing, urban development, labour and labour welfare, social security and welfare, nutrition and relief). The primary source is an annual publication, Public Finance Statistics (Ministry of Finance, Government of India). This information is also collated in the Reserve Bank of India's annual publication Report on Currency and Finance.

The data on **political histories** comes from Butler, Lahiri and Roy [1991]. This primary data is aggregated into four political groupings which are defined in the text and expressed as shares of the total number of seats in state legislatures. State political configurations are held constant between elections. Political history is measured by the number of years during our data period that particular political groupings have held a majority of the seats in the legislature. In our data period, the relevant groupings are: the Congress party, the Janata parties, hard left parties and regional parties. These groupings contain the following parties (i) Congress Party (Indian National Congress + Indian Congress Socialist + Indian National Congress Urs + Indian National Congress Organization), (ii) Janata parties (Lok Dal+Janata+Janata Dal), (iii) a hard left grouping (Communist Party of India + Communist Party of India Marxist), and a (iv) grouping made up of regional parties.

For our measure of **unionization** we use the number of union members in a state divided by the state population and averaged over the pre-1977 period. The source of this data is the Indian Labor Yearbook, Labor Bureau, Ministry of Labor, Government of India. For the matched estimation we rank states by this variable and then match treatment states to control states with the closest level of pre-1977 unionization. The treatment-control matches are as follows: Andhra Pradesh-Uttar Pradesh, Gujarat-Bihar, Karnataka-Haryana, Kerala-Bihar, Madhya Pradesh-Uttar Pradesh, Maharashtra-Assam, Orissa-Uttar Pradesh, Rajasthan-Uttar Pradesh, Tamil Nadu-Assam, West Bengal-Assam. For our historical **land tenure** measure we used data from Banerjee and Iyer [2002] who classified the land revenue system imposed in each district of British India as landlord or non-landlord based. To construct our state measure we took the mean value for constituent districts of modern states weighting each by land area of the district.

Our **disaggregated registered manufacturing data** come from the Annual Survey of Industries which reports information on production activity in the registered manufacturing sector across the sixteen main Indian states for more than 100 3-digit industries during 1980-97.

The **poverty** figures we use for the rural and urban areas of India's 16 major states, spanning 1957-58 to 1991-92 were put together by Ozler, Datt and Ravallion [1996]. These measures are based on 22 rounds of the National Sample Survey (NSS) which span this period. The NSS rounds are not evenly spaced: the average interval between the midpoints of the surveys ranges from 0.9 to 5.5 years. Surveys were carried out in the following years 1958, 1959, 1960, 1961, 1962, 1963, 1965, 1966, 1967, 1968, 1969, 1970, 1971, 1973, 1974, 1978, 1983, 1987, 1988, 1990, 1991, 1992. Because other data are typically available on a yearly basis weighted interpolation has been used to generate poverty measures for years where there was no NSS survey. The poverty lines used are those recommended by the Planning Commission [1993]. The headcount measures are estimated from the grouped distributions of per capita expenditure published by the NSS, using parameterized Lorenz curves using a methodology detailed in Datt and Ravallion [1992].

Table 1: Descriptive Statistics: 1958 - 1992

	Mean	Standard deviation
Labor regulation	-0.148	0.925
Works days lost to strikes per worker	4.350	11.90
Works days lost to lockouts per worker	1.628	6.470
Log registered manufacturing output per capita	4.252	0.796
Log unregistered manufacturing output per capita	3.900	0.513
Log registered manufacturing employment	12.44	1.056
Log registered manufacturing fixed capital per capita	0.709	0.846
Log registered manufacturing value added per employee	-11.72	0.497
Urban poverty headcount (percent)	43.14	12.76
Rural poverty headcount (percent)	50.79	14.08
Log develop expenditure per capita	4.368	0.824
Log installed electricity capacity per capita	6.677	1.214
Log state population	10.31	0.727
Congress majority	12.95	7.767
Hard left majority	0.377	1.711
Janata majority	0.616	1.440
Regional majority	1.284	4.070

Notes: The data are for the sixteen main states for the period 1958 - 1992. Haryana split from the Punjab in 1965 and, after this date, we include Haryana as a separate observation. We therefore have a total of 552 possible observations with deviations accounted for by missing data. See the Data Appendix for details on the construction and sources of the variables.

Table 2: Labor Regulation and Industrial Disputes in India: 1958-1992

	(1)	(2)	(3)	(4)

Notes: Absolute t statistics calculated using robust standard errors clustered at the state level are reported in parentheses, \* significant at 10%, \*\* significant at 5%, \*\*\* significant at 1%. Registered manufacturing employment refers to total employment in factories and daily employment is defined as total worker attendances over a year divided by the total number of days worked by the factory. Earnings per worker is obtained by dividing total annual remuneration by the number of workers. Fixed capital represents the depreciated value of fixed assets owned by the factory on the closing date of the accounting year. The number of factories refers to the number in the registered manufacturing sector in each state where adjustments are made for deregistration and new entrants. Value-added per employee is obtained by deducting the value of total inputs and depreciations from the value of output and dividing this by the number of employees in a factory. State amendments to the Industrial Disputes Act are coded 1=pro-worker, 0=neutral, -1=pro-employer and then cumulated over the period to generate the labor regulation measure. Installed electrical capacity is measured in kilowatts and development expenditure is real per capita state spending on social and economic services. Congress, hard left, Janata and regional majority are counts of the number of years for which these political groupings held a majority of the seats in the state legislatures. The data are for the sixteen main states for the period 1958 - 1992. Haryana split from the Punjab in 1965 and, after this date, we include Haryana as a separate observation. We therefore have a total of 552 possible observations with deviations accounted for by missing data. See the Data Appendix for details on the construction and sources of the variables.

Table 6 Labor Regulation and Industrial Performance : Dealing with Endogeneity Concerns

	(1)	(2)	(3)	(4)	(5)	(6)	(7)

Observations	283	283	300	480	480	517	525

Notes: Absolute t statistics calculated using robust standard errors are reported in parentheses, \* significant at 10%, \*\* significant at 5%, \*\*\* significant at 1%. For columns (1) - (3) we use the average level of union membership (union members divided by population) before 1977 and use these data to match states that experience labor market reforms (pro-worker or pro-employer) with control states based on the level of unionization. We then regress labor regulation on the difference between registered manufacturing in a 'treatment' state and that in its matched 'control' state while also including match dummies in the regression. Standard errors in columns (4) – (6) are clustered at the state level. The two instruments for our lagged [t-1] labor regulation measure are: (i) the pre-1977 unionization measure interacted with a post-1997 dummy and (ii) the proportion of constituent districts of modern states which operated non-landlord land revenue systems in British India interacted with a post-1977 dummy. The overidentification test we employ is due to Sargan [1958]. The number of observations times the R<sup>2</sup> from the regression of the stage two residuals on the instruments is distributed  $\chi^2(T+1)$  where T is the number of instruments. State amendments to the Industrial Disputes Act are coded 1=pro-worker, 0=neutral, -1=pro-employer and then cumulated over the period to generate the labor regulation measure. Installed electrical capacity is measured in kilowatts and log development expenditure is real per capita state spending on social and economic services. The data are for the sixteen main states for the period 1958 - 1992. Haryana split from the Punjab in 1965 and, after this date, we include Haryana as a separate observation. We therefore have a total of 552 possible observations with deviations accounted for by missing data. See the Data Appendix for details on the construction and sources of the variables.

Notes: Absolute t statistics calculated using robust standard errors clustered at the state-industry level are reported in parentheses, \* significant at 10%, \*\* significant at 5%, \*\*\* significant at 1%. The data used in the regressions is a panel data set on 3-digit registered manufacturing industries across the sixteen main states of India for the period 1980-1997. The data form an unbalanced panel. Our analysis retains state industries which remain in the panel for at least ten years and within these industries we restrict our attention to firms which employ more than a hundred workers to get around the problem of smaller firms being excluded from the sample to maintain confidentiality. Using this a definition we have total of 101 3-digit industries in our panel with an average of 68 in each state. State amendments to the Industrial Disputes Act are coded 1=pro-worker, 0=neutral, -1=pro-employer and then cumulated over the period to generate the labor regulation measure. The regressions include 3-digit industry time trends to help control for the possibility that industries experience different rates of technological change. See the Data Appendix for details on the construction and sources of the variables.

Notes: Absolute t statistics calculated using robust standard errors clustered at the state level are reported in parentheses, \* significant at 10%, \*\* significant at 5%, \*\*\* significant at 1%. Poverty headcount is the percentage of the population below the official Indian poverty lines which are separately defined for rural and urban areas. In column (4) the rural-urban poverty difference is the difference between the rural and urban headcount measures for each state. In column (7) we only include data for years when National Sample Surveys were carried out. State amendments to the Industrial Disputes Act are coded 1=pro-worker, 0=neutral, -1=pro-employer and then cumulated over the period to generate the labor regulation measure. Installed electrical capacity is measured in kilowatts and development expenditure is real per capita state spending on social and economic services. Congress, hard left, Janata and regional majority are counts of the number of years for which these political groupings held a majority of the seats in the state legislatures. The data are for the sixteen main states for the period 1958 - 1992. Haryana split from the Punjab in 1965 and, after this date, we include Haryana as a separate observation. We therefore have a total of 552 possible observations with deviations accounted for by missing data. See the Data Appendix for details on the construction and sources of the variables.

Appendix Table: Regulatory Change in India: 1958 - 1992

State	Change Year	Amendments and codes	Overall Code
Andhra Pradesh	1968	Limits strikes and lockouts in designated public utilities [-1].	Pro-employer
	1982	Facilitates settlement of industrial disputes in labor courts [-1]	Pro-employer
	1987	Prohibits strikes and lockouts when in the public interest [-1]. Workers have to be paid before closing down firm [1]. Prior workers given preference when rehiring [1]. Dismissed workers paid from reinstatement not rehiring date [1]. Imposes penalty for not complying with order prohibiting industrial disputes [-1]. Individual workers can apply to labor court for adjudication [1]. Widens judicial powers to recover money owed to workers by employer [1]. Lengthens the notice employer must give worker about change in conditions of service [1].	Pro-worker
Gujarat	1973	Imposes penalty on employer for not nominating representatives to councils within firms [1].	Pro-worker
Karnataka	1988	Individual workers can apply to labor court for adjudication [1]. Enforces attendance at industrial dispute hearings [-1]. Empowers state governments to transfer disputes across tribunals to facilitate settlement [-1]. Prohibits strikes and lockouts when in the public interest [-1]. Extends rules for layoff, retrenchment and closure to smaller firms [1].	Pro-employer
Kerala	1979	Prohibits strikes and lockouts when in the public interest [-1]. Imposes penalty for not complying with order prohibiting industrial disputes [-1].	Pro-employer
Madhya Pradesh	1982	Extends powers of labor courts to settle industrial disputes. [-1]. Facilitates settlement of industrial disputes in labor courts [-1]	Pro-employer
	1983	Applies closure rules to previously uncovered undertakings [1].	Pro-worker
Maharashtra	1981	Compensation now received for closure due to lay-off [1]. Workers receive 100% as opposed to 50% of wages for layoff due to electricity problems [1]. Extends rules for layoff, retrenchment and closure to smaller firms [1].	Pro-worker
	1983	Gives power of appeal to workers to overturn decision to close down firm [1].	Pro-worker
Orissa	1983	Extends rules for layoff, retrenchment and closure to smaller firms [1]. Gives power of appeal to workers to overturn decision to close down firm [1].	Pro-worker
Rajasthan	1960	Exact criteria for being union member defined [-1]. Defines employers in firms sub-contracted to industry as employers for industrial disputes purposes [1]. Defines who is allowed to be involved in bargaining process on behalf of unions [-1]. Gives definition of what a union is in an industrial dispute [-1]. Definition of worker for industrial disputes purposes extends to those subcontracted with an industry [1].	Pro-employer
	1970	Empowers the states to refer industrial disputes to industrial tribunals when it is in the public interest [-1]. Prohibits strikes and lockouts when in the public interest [-1]. Imposes penalty for not complying with order prohibiting industrial disputes [-1]. Widens judicial powers to recover money owed to workers by employer [1]. Defines union registration rules to prevent multiple representation [-1].	Pro-employer
	1984	Extends rules for layoff, retrenchment and closure to smaller firms [1]. Can continue lay-offs due to natural disasters for more than 30 days without permission [-1]. Union representative has to be involved in negotiations concerning retrenchment of workers [1]. Applies closure rules to previously uncovered undertakings [1]. Increases penalty for unauthorized layoff and retrenchment of workers [1]. Extends rules for layoff, retrenchment and closure to smaller firms [1].	Pro-worker

Tamil Nadu	1982	Prohibits strikes and lockouts when in the public interest [-1]. Imposes penalty for not complying with order prohibiting industrial disputes [-1].	Pro-employer
West Bengal	1974	Prohibits lay-off of worker given employment on same day [1].	Pro-worker
	1980	Includes workers involved in sales in definition of worker [1]. Retrenchment does include workers terminated on grounds of ill-health [1]. Extends period within which report of conciliation proceedings must be submitted [1]. Extends date at which conciliation proceedings are deemed to have started [1]. Facilitates settlement of industrial disputes in labor courts [-1]. Facilitates the making of awards by labor courts [1]. Limit on the number of days laid off workers receive 50% of their wages is removed [1]. Laid off worker only have to present themselves once a week at the plant if lay off extends for more than seven days [1]. Workers have to be paid before closing down firm [1]. Prior workers given preference when rehiring [1]. Dismissed workers paid from reinstatement not rehiring date [1]. Extends rules for layoff, retrenchment and closure to smaller firms [1]. Extends period after which employer can commence lay-off [1]. Widens judicial powers to recover money owed to workers by employer [1]. Lengthens the notice employer must give worker about change in conditions of service [1].	Pro-worker
	1986	Makes transparent the award procedures to be followed and relief to be given to discharged, dismissed or retrenched workers.	Pro-worker
	1989	Individual workers can apply directly to conciliation officer and labor court for adjudication [1]. Employers have to demonstrate ability to pay compensation to pay workers before closing down firm [1]. Refusal of employment is grounds for an individual worker to enter into an industrial dispute [1].	Pro-worker

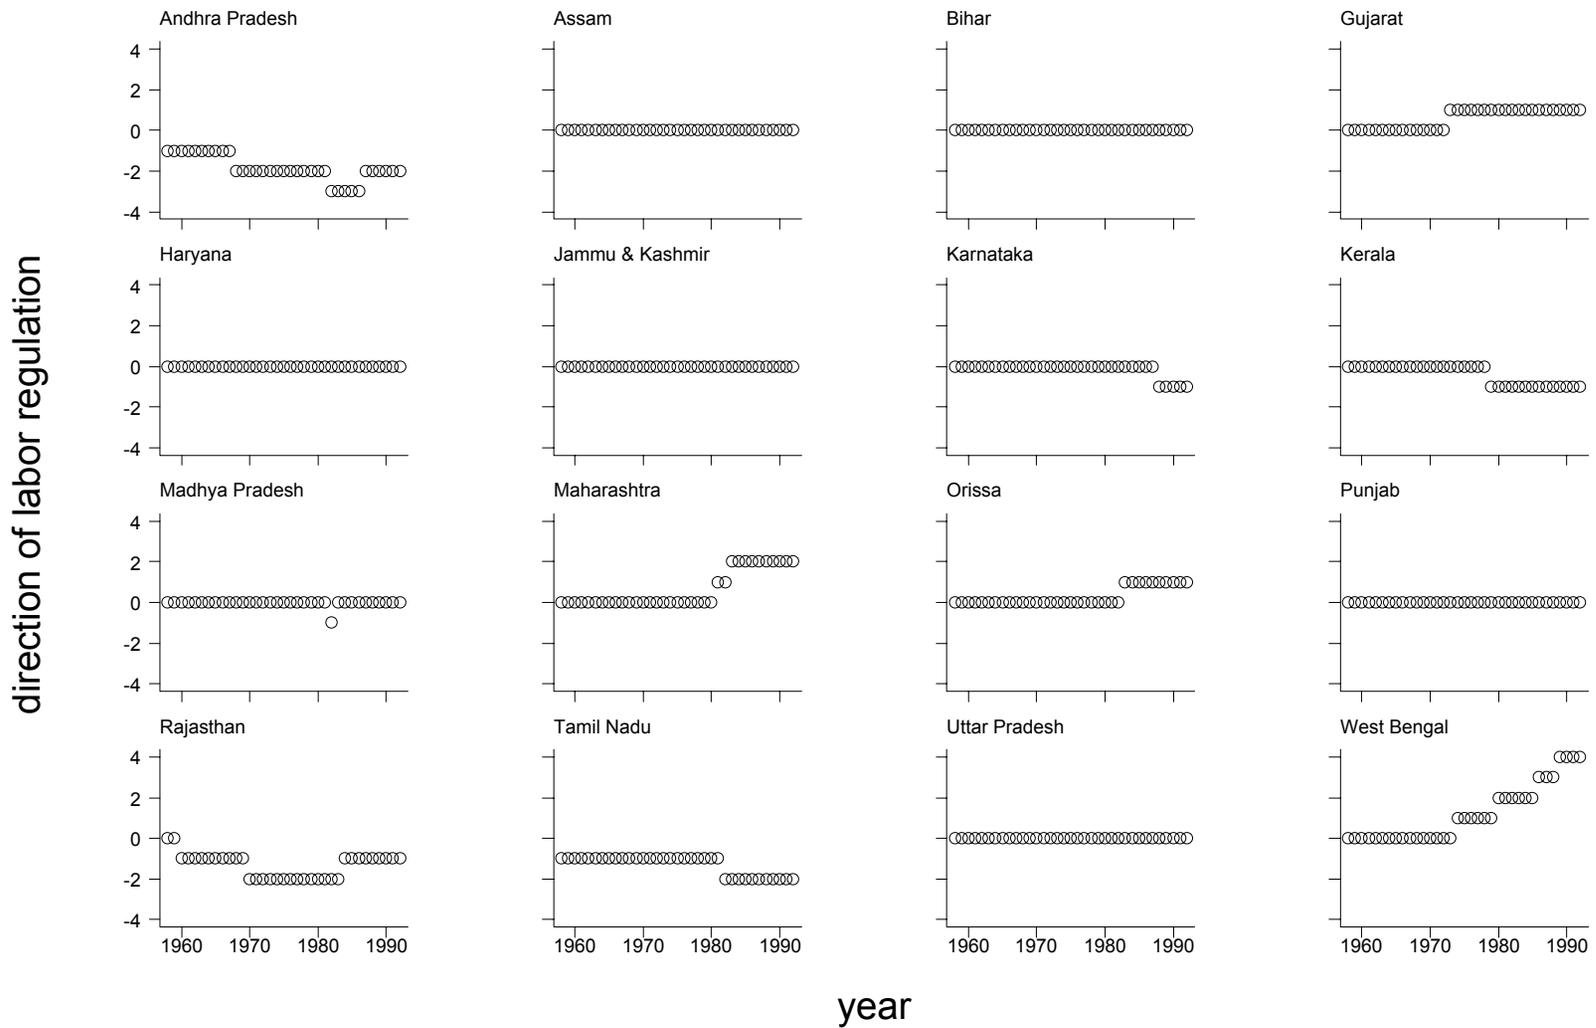

Figure 2: Labor Regulation in India: 1958-1992

### Derivation of 0.3%-point increase in growth from the implementation of “employment-at-will”<sup>1</sup>

A baseline study in the literature of the impact of employment protection on productivity and therefore output and growth is by David Autor, William Kerr and Adriana Kugler. Their research shows that mandated employment protection reduces productivity, employment, and new firm entry and gives firms the incentive to replace labor with capital.<sup>2</sup> These issues are exacerbated in economies that have relatively large informal sectors as is the case in Puerto Rico.<sup>3</sup>

In view of the strong econometric results of the negative impact of employment protection on employment, we then looked to find estimates of the impact of employment protection reform on growth. The most comprehensive study that we found looked at the significant labor market reforms taken in countries in the Euro Area periphery in the last decade. These countries face an economic environment very similar to that of Puerto Rico—strong economic links to a much larger economic entity and no independent monetary and exchange rate policies. The policies pursued by these countries were broader in scope and included reforms on both the demand and supply of labor, including, streamlining employment protection legislation, reforming unemployment benefits, increasing child support, and pension reform. All told these reforms made labor markets more flexible, increased labor supply, and led to a long-run additional 3.5% annual growth in peripheral European countries. Key to our analysis here was the finding that the elimination of employment protection (which goes at the heart of “employment-at-will” reforms), within the context of these broader reforms, **accounted for 0.5% of permanent growth.**<sup>4</sup>

In the case of Italy, the growth impact of easing employment protection was assumed to raise productivity and thereby growth by 0.3 percentage points, as the Italian reform did not reach the level of OECD best practices.<sup>5</sup> A follow up study in Italy showed that employment protection deregulation improved the quality of matches in the Italian labor market in the second year after implementation, with the odds of a worker being well-matched increasing by almost 16%. The employment protection reform, by increasing labor turnover that, in turn improves matching, resulted in higher productivity.<sup>6</sup>

Easing employment protections through at-will employment policies would lower the cost of hiring that is substantially elevated by the potential cost of litigation. Such costs can be burdensome and thus a barrier to hiring. In a study of claims reported by small-to medium-sized enterprises, 19% of employment costs were due to defense and settlement costs to employers averaging \$125,000, well above the median salary in the US.<sup>7</sup> When claims are brought to court, the damages can be even higher: the median judgement is approximately \$200,000, and a quarter of cases result in a judgment over \$500,000 – above and beyond the legal cost of defense. In addition to this direct cost, firms additionally engage in activities to avoid litigation risk by hiring fewer workers than optimal, with resulting production inefficiencies. Dertouzos and Karoly found that wrongful termination liability creates substantial costs beyond those directly attributable to lawsuits, as employers alter their use of labor to reduce their exposure to litigation.<sup>8</sup>

In the scoring of the overall labor reform that envisages 1 full percentage point of permanent growth from the entire labor reform package, about half would come from the labor supply side through the EITC and limited work-requirement for PAN (where the literature shows estimates of permanent growth impacts of between 0.3% and 0.8%), and half from the labor demand side. Consistent with the Italian experience and the IMF study noted above, it was estimated that about 0.3% points would come from easing employment protection (i.e., implementing employment-at-will) and 0.2% points from eliminating benefit requirements, such as generous paid vacation.

## CURRICULUM VITAE

**Andrew M. Wolfe**  
**2634 Starboard Point Drive**  
**Houston, TX 77054**

**NATIONAL OF:** United States

### CURRENT POSITIONS:

Adjunct Professorial Lecturer, American and Rice Universities  
 Fiscal Consultant for the Inter-American Development Bank  
 Economic Advisor to the Puerto Rico Financial Oversight and Management Board

### EDUCATION:

1978	B.S.E., Economics, University of Pennsylvania
1978	B.A.S., Engineering, University of Pennsylvania
1985	Ph.D., Economics, University of Wisconsin

### LANGUAGES:

English-Native  
 Spanish-Fluent

### UNIVERSITY EXPERIENCE:

2017 –present	Rice University, Adjunct Faculty in the James Baker School of Public Policy
2013- present	American University, Adjunct Faculty in the School of International Studies
1983- 1986	Bowdoin College, Assistant Professor

### IMF CAREER:

1987-1992	Economist, Western Hemisphere Department (WHD)
1992-1995	Resident Representative, Uruguay (1992-95) and Argentina (1994-95)
1995-1997	Senior Economist, Fiscal Affairs Department
1997-2000	Resident Representative, Peru
2001-2002	IMF Mission Chief, Peru
2002-2005	IMF Mission Chief, Uruguay
2005-2006	Senior Resident Representative, Argentina
2006-2009	IMF Mission Chief, Dominican Republic
2009-2011	IMF Mission Chief, El Salvador and Colombia
2011-2014	Senior Personnel and Budget Manager, WHD, Head of IMF Human Resource Strategy Unit

# Do Foreign Investors Care about Labor Market Regulations?

Beata Smarzynska JAVORCIK<sup>♦</sup>#

and

Mariana SPATAREANU<sup>♦</sup>

Forthcoming in *Weltwirtschaftliches Archiv*

**Abstract:** This study investigates whether labor market flexibility affects foreign direct investment (FDI) flows across 19 Western and Eastern European countries. The analysis uses firm level data on new investments undertaken during 1998-2001. The study employs a variety of proxies for labor market regulations reflecting the flexibility of individual and collective dismissals, the length of the notice period and the required severance payment along with controls for business climate characteristics. The results suggest that greater flexibility in the host country's labor market in absolute terms or relative to that in the investor's home country is associated with larger FDI inflows.

\*The authors would like to thank Mathias Busse, Holger Görg, Jan Rutkowski, Maurice Schiff and an anonymous referee for helpful comments and suggestions and Simeon Djankov for providing an index of labor market flexibility. The views expressed in the paper are those of the authors and should not be attributed to the World Bank or its Executive Directors.

## Introduction

While the existing empirical literature on foreign direct investment (FDI) has examined the effect of various regulatory determinants on investment flows,<sup>1</sup> no attention has been paid to one key aspect of government regulations, namely the flexibility of labor markets, despite the fact that both the anecdotal evidence and the theoretical literature suggest it ought to be important. For instance, a recent article in the *Financial Times* carried a headline stating that “Archaic Labor Laws Stop Europe Working” and argued that in the presence of labor regulations that make it hard to dismiss and to hire workers, companies can neither grow nor take advantage of new business opportunities.<sup>2</sup> Similarly, *The Economist* magazine suggested that increasing labor market flexibility is seen as crucial to the revitalization of the European economy, particularly after the accession of several Central and Eastern European Countries to the European Union.<sup>3</sup> The lack of flexibility in hiring and laying off workers is also one of the main concerns raised by investors operating in or considering entering transition economies and developing countries (Moran 1998, p. 89). This view is further echoed in a theoretical paper by Haaland et al. (2003) who demonstrate a trade-off between FDI incentives and labor market flexibility and conclude that a country with a more flexible labor market (i.e., lower redundancy payments) should find it easier to attract FDI.

This study aims to fill the gap in the literature by testing empirically whether host country’s labor market flexibility, in absolute terms or relative to that in the investor’s home

---

<sup>1</sup> Wei and Schleifer (2000) examine the consequences of FDI incentives and restrictions on investment flows, Hines (1996) and Devereux and Griffith (1998) the effect of taxation, Javorcik (2004) the impact of intellectual property protection, Keller and Levinson (2002) and Javorcik and Wei (2004) the effect of environmental standards.

<sup>2</sup> *Financial Times*, March 5, 2004.

<sup>3</sup> “Many mid-cap businesses in Germany are looking aggressively at opportunities in new member states. Already workers at several German companies have reacted by accepting longer working hours for the same pay” (*The Economist*, November 6th, 2004).

country, affects the location decisions of multinationals. To the best of our knowledge, the only analysis of this question can be found in a paper by Dewit et al. (2003) who consider the impact of labor laws on aggregate FDI flows within the OECD countries in 1989 and 1998 and find that an unfavorable employment protection differential between a domestic and a foreign location is inimical to FDI.<sup>4</sup> In contrast to the work of Dewit et al. (2003), our analysis is based on firm level data and employs a much more detailed set of proxies for labor market regulations.

One of the advantages of employing firm level data is that we are able to explicitly control for the investing firm's characteristics that affect the investment decision, such as the firm size, previous FDI experience and the nature of business (i.e., manufacturing versus services). We are also able to consider a specification that takes into account unobserved investor characteristics. We use information on new subsidiaries established by the largest 10,000 European companies in 19 Western and Eastern European countries during 1998-2001. The information comes from a commercial database *Amadeus* compiled by Bureau van Dijk. Western European countries and transition economies of Eastern Europe are well suited for studying this question, as they offer a large variation in terms of labor market regulations. In both Western and Eastern Europe we can find economies with highly inflexible labor markets (France and Poland) as well as countries giving employers relative freedom in hiring and firing decisions (United Kingdom and Bulgaria).

We employ a comprehensive set of labor market flexibility measures along with a large set of controls for business climate characteristics. The former include indices compiled by Djankov et al. (2001) reflecting the flexibility of individual dismissals, the flexibility of collective layoffs, the length of the notice period and the required severance payment, as well as

---

<sup>4</sup> Görg (2002) addresses a similar question using the data on the stock of US outward FDI and focusing only on the level of labor market flexibility in a host country rather than the differential between the home and the host economy.

a proxy for the flexibility of hiring and firing practices from the *Global Competitiveness Report 2001-2002* produced jointly by the Geneva-based World Economic Forum and the Center for International Development at Harvard University. Moreover, we control for the presence of restrictions on FDI inflows, protection of property rights, the level of corporate taxation and the quality of governance. Finally, we include measures of the market size and labor costs.

The results suggest that greater flexibility in the host country's labor market is associated with a higher probability of investment taking place as well as with a larger volume of investment. The same holds true for the difference between the labor market regulations in the host and the source country. When we interact the effect of labor market flexibility with a dummy for services sectors, we find that investors entering these industries are even more sensitive to labor market regulations. We also show that taking into account the presence of transition economies in the sample does not change the results.

The paper is structured as follows. In the next section we discuss the empirical model, the data and the variables definitions. Then we present the empirical results. The last section contains concluding remarks.

## **Empirical Strategy**

### **Model and Estimation Issues**

The basic question we seek to answer is whether labor market flexibility affects the flow of foreign direct investment across countries. In doing so we also consider a number of other

potential determinants of location choice, as suggested by the existing literature.<sup>5</sup> We employ two empirical strategies to address this question. First, we focus on the location of foreign subsidiaries ignoring the size of investment. We estimate a fixed effect logit model

$$\begin{aligned}
 FDI_{ic} &= 1 \text{ if } FDI_{ic}^* > 0 \\
 FDI_{ic} &= 0 \text{ otherwise} \\
 \text{where} \\
 FDI_{ic}^* &= d_i + X_c \theta + \beta Flexibility_{ic} + u_{ic}
 \end{aligned} \tag{1}$$

where the dependent variable takes on the value of one if firm  $i$  has invested in country  $c$ , and zero otherwise. For each firm the number of observations is equal to the number of possible destination countries in the sample. To control for unobservable firm characteristics, firm specific fixed effects ( $d_i$ ) are used. On the right hand side, we include the index of the host country's labor market flexibility ( $Flexibility_c$ ) or the difference in the labor market flexibility between the host and the source country ( $Flexibility_{ic} = Flexibility_c - Flexibility_i$ ) as well as other controls for host country characteristics ( $X_c$ ). Since our prior is that more flexible labor market regulations in the host country (in absolute terms or relative to the source country) are associated with a greater likelihood of foreign investment, we expect  $\beta > 0$ .

Then we focus on the size of investment and estimate the following equation

$$\ln(FDI \text{ volume}_{ic} + 1) = \alpha + X_i \Pi + X_c \Psi + \delta Flexibility_{ic} + \varepsilon_{ic} \tag{2}$$

where the volume of investment undertaken by firm  $i$  in country  $c$  is regressed on the characteristics of firm  $i$  and its home country ( $X_i$ ), variables specific to destination country ( $X_c$ ) and the proxy for labor market regulations ( $Flexibility_c$  or  $Flexibility_{ic}$ ). Again we expect  $\delta$  to be positive. The number of observations for each firm is equal to the number of potential

---

<sup>5</sup> For a literature review on FDI determinants see Wheeler and Mody (1992) and Markusen (1995).

investment destinations, with the *FDI volume* equal zero for countries in which firm *i* does not have any investments. To avoid losing all observations for which *FDI volume* takes on the value of zero, we add one before taking the logarithm of the variable. Given that most firms have subsidiaries only in some of the 19 possible destination countries considered and some firms have no subsidiaries at all, in a large number of cases the dependent variable is equal to zero. Therefore, we employ the Tobit model, as using OLS would lead to inconsistent estimates.

The choice of the model is determined by the data availability. As explained below, our data set contains a comprehensive listing of the existing subsidiaries of firms included in the sample, but the information on the volume of investment is available only for a subset of them. The logit specification allows us to maximize the sample coverage, while the Tobit regression enables us to examine the determinants of the investment volume. We view the two approaches as complementary.

## **FDI Data**

The data used in this study come from the commercial database *Amadeus* compiled by Bureau van Dijk, which contains comprehensive information on approximately 5 million companies operating in 35 European countries. In addition to the standard financial statements, *Amadeus* includes complete information on the ownership structure of firms, which allows us to identify the ownership stakes held by each company in entities located in other countries. We are thus able to construct a unique data set containing detailed information about European firms and all of their domestic and foreign subsidiaries.

We focus our attention on the largest 10,000 firms operating in Europe (with the size measured by the value of total assets in 1999) and their subsidiaries located in 14 Western

European and 5 Central and Eastern European countries, including Bulgaria, the Czech Republic, Hungary, Poland and Ukraine. The choice of host countries is driven by two considerations: by the fact that information on the size of investment is available only for European subsidiaries and by our decision to restrict the analysis to subsidiaries established between 1998 and 2001. We construct the data set on new subsidiaries by comparing the subsidiary listings for companies included in both the 1998 and the 2001 versions of the *Amadeus* database.<sup>6</sup> The ownership information pertains mostly to year 2000 and in some cases to 1999. If a firm has more than one subsidiary in a given country, we focus our attention on the one with the highest value of the parent company's equity participation. The sample also includes non-investors that is, firms without any subsidiaries in foreign countries.<sup>7</sup>

After deleting firms with missing information and removing outliers,<sup>8</sup> the data set contains 7,150 parent firms with 6,391 subsidiaries in 19 destination countries, including the home country, of which 3,053 are foreign subsidiaries. The potential number of observations is thus equal to  $7,150 \times 19 = 135,850$  investment decisions at the firm level. The *Amadeus* database provides a good reflection of FDI inflows into the host countries considered. The correlation between the FDI inflows reported by UNCTAD for 1999-2000 and the total value of foreign assets in the subsidiaries listed in *Amadeus* and created in the same group of host countries during the same period is .61.<sup>9</sup>

---

<sup>6</sup> We chose not to go further back in time as the earlier versions of the database were much smaller in size and contained only very limited information on subsidiaries in Eastern Europe.

<sup>7</sup> Such firms drop out from the fixed effect logit estimation but are included in Tobit regressions.

<sup>8</sup> Firms with negative or unusually large values for sales, total assets or employment were dropped from the sample.

<sup>9</sup> Total FDI inflows were calculated by subtracting the total FDI stock as of end-1998 from the corresponding figure for end-2000, as reported in the UNCTAD online database ([www.unctad.org](http://www.unctad.org)). To calculate total FDI inflows based on the *Amadeus* data we considered only subsidiaries with more than 10% foreign ownership.

## Variable Definitions

The dependent variable in Equation (1) is equal to one if the database indicates the existence of firm  $i$ 's subsidiary in country  $c$ . In Equation (2), we construct *FDI volume* by multiplying the percentage of the equity owned by firm  $i$  in its subsidiary located in country  $c$  by the total assets of the subsidiary. If firm  $i$  has more than one subsidiary in country  $c$  we use the largest investment. If no subsidiary exists, the variable takes on the value of zero. All information from the *Amadeus* database presented in national currencies is converted to U.S. dollars using the average market exchange rate for the given year from the IMF's *International Financial Statistics*.

In addition to taking into account conditions in the host country, our data set provides us with an opportunity to control for characteristics of parent companies. We do so only in Equation (2) as Equation (1) includes parent fixed effects. As larger firms and firms with greater international experience may be more likely to expand into foreign countries (see Javorcik 2004 for empirical evidence), we control for the firm size using the value of total assets and for the international experience by including the total number of foreign subsidiaries. In order to avoid simultaneity we use the values of these variables pertaining to 1998, which is the first year considered in our sample.<sup>10</sup> We expect to find a positive coefficient on both variables. We also take into account the population size, the average wage and GDP per capita of the source country, expecting that more FDI is likely to come from larger and richer countries and from economies with higher labor costs. The average wage is calculated as the average of wages paid

---

<sup>10</sup> Note that the number of subsidiaries pertains to investments located all over the world, not just in the 19 countries considered in our sample.

by the top 10,000 firms in each country.<sup>11</sup> The population and GDP per capita figures come from the World Bank's *World Development Indicators*.

Since the purpose of our paper is to test for the effect of labor market flexibility on the multinational firm's decision to invest in various countries, it is crucial to have plausible measures of labor market regulations. The first measure used in our analysis is the *Index of Flexibility of Hiring and Firing Practices* from the *Global Competitiveness Report 2001-2002* (hereafter GCR index) published jointly by the Geneva-based World Economic Forum and the Center for International Development at Harvard University. It is a country specific index that quantifies the average response to the survey question: "Is hiring and firing of workers impeded by regulations or flexibly determined by employers?" It takes on the value of 7 for a very flexible labor market and 1 in the case of the most rigid ones. Since it is based on the views of "business practitioners" in each country, it captures not only laws on the books but also their enforcement.

We also include four additional measures, compiled by Djankov et al. (2001), reflecting the strength of employment protection legislation, which relates to employers' liberty to lay off workers. These are: *the Index of the Flexibility of Individual Dismissal Procedures*, *the Index of the Flexibility of Collective Dismissal Procedures*, *the Index of Notice and Severance Payment* and *the Overall Index of Rules of Dismissal*.<sup>12</sup> These indices rely on information collected in 2001 and thus match well the time period of our sample. The value for the *Overall Index of Rules of Dismissal* ranges from 0 to 12, with 0 representing very strict rules of dismissal and 12 the most ample ones. Thus, the higher the index value, the less costly it is for the employer to dismiss workers. The indices are country specific but, since firing costs are usually comparable

---

<sup>11</sup> Top 10,000 firms in decreasing order of total assets and with more than 5 employees in 1999.

<sup>12</sup> These indices were also used by Botero et al. (2004).

across industries as they are set by the national legislation, the use of country level data is appropriate.

As illustrated in Figures 1 and 2, there is a large variation in the 19 countries considered in our sample in terms of labor market flexibility. In both Western and Eastern Europe we can find economies with inflexible labor markets (France and Poland) as well as countries giving employers relative freedom in hiring and firing decisions (Denmark and Hungary). While there are some differences in individual rankings between the GCR and the Overall Index of Rules of Dismissal, the two measures appear to be highly correlated (see Figure 3). Therefore, we start our analysis by including labor market indices one by one in the regressions. As higher labor market flexibility is associated with lower costs of doing business, we expect to find a positive relationship between the probability of FDI or the investment volume and the host country's flexibility of labor markets. Recognizing that impediments to adjusting employment numbers constitute a push factor encouraging firms to transfer production out of their own country as well as a pull factor enticing firms to enter economies with flexible rules, we also focus on the difference in labor market flexibility between the host and the source country. As *higher* values of the variable correspond to *greater* flexibility in the host country relative to the source country, we expect to find a *positive* relationship between  $Flexibility_{ic}$  and the likelihood or the volume of investment.

Turning to other host country characteristics, we control for factors commonly mentioned in the literature as determinants of FDI, including proxies for the market size (population size) and the labor costs in the host country (average wage). We expect that larger markets attract investors while higher labor costs act as a deterrent. As in the case of labor market flexibility variables, we also allow for the difference in labor costs between the home and host country. The

higher the labor costs difference between the home and the host country, the higher the likelihood of FDI or the volume of investment.<sup>13</sup>

We also control for various aspects of the business climate in the host country. The first control is the FDI Restrictions Index derived by Wei and Schleifer (2000) based on reading the detailed country reports produced by PricewaterhouseCoopers. The index focuses on four areas: the existence of foreign exchange controls (which may interfere with foreign firms' ability to import intermediate inputs or repatriate profits abroad), the exclusion of foreign firms from strategic sectors (e.g., defense industry, media), the exclusion of foreign firms from other sectors, and restrictions on the share of foreign ownership. Each of these four dimensions is represented by a variable taking on the value of 1 in the presence of restrictions and 0 otherwise. The overall index is defined as the sum of these variables and ranges from 0 (no restrictions) to 4 (restrictions present in all areas).

The second control is the Index of Property Rights, which comes from the *Global Competitiveness Report 2001-2002*. It is based on an extensive survey of managers who were asked to rate on the scale 1 to 7 whether the "property rights [in a given country] are clearly delineated and protected by law." Subsequently, the arithmetic mean of all responses by country was reported. A score of 7 corresponds to countries with well protected property rights and 1 to the countries with little or no protection. This variable is intended to capture the country specific risk that multinational firms may face from possible expropriation of assets, insecurity of property rights and contracts.

---

<sup>13</sup> Some of the existing studies on location decision of multinational firms include wages, while others control for both wages and labor productivity. The results are mixed. Coughlin et al. (1991) and Friedman et al. (1992) find that higher wages deter foreign direct investment, while Ondrich and Wasylenko (1991) do not detect a statistically significant relationship. Only Friedman et al. (1992) controls explicitly for productivity and finds a positive correlation. More recently, Thomsen (1995) shows that the location of export platforms of US FDI in European countries is negatively affected by unit labor costs.

Another potentially important factor influencing the FDI location is the level of corporate taxation in the host country, as demonstrated by Hines (1996) and Devereux and Griffith (1998). We employ the corporate tax rates reported by PricewaterhouseCoopers. All taxes are expressed in percentages; if several rates apply, the highest one is used. We anticipate that high tax rates deter FDI. We also expect the difference in taxation rates between the home and the host country to be positively correlated with the probability of investing abroad as well as with the volume of investment.<sup>14</sup>

Finally, we add a dummy variable for transition countries to control for other differences between industrialized and transition economies that may not be captured by the explanatory variables. For instance, if a large presence of foreign investors encourages subsequent inflows due to agglomeration effects and transmission of knowledge about the host country to source economies, then transition countries are at a disadvantage vis-à-vis Western Europe as they have opened to FDI relatively recently.

All variables definitions and data sources are summarized in Table 1.

As can be seen in Table 2, a large degree of heterogeneity is found in terms of the business environment in host countries in our sample. Transition economies usually rank low with respect to property rights protection. However, the picture is mixed with regard to FDI incentives, labor market flexibility and corporate taxation, as in both Western as well as Eastern Europe we find countries with very different scores in these areas. For instance, while some transition economies, especially Hungary, the Czech Republic and Poland, have no or very few restrictions on FDI, others, such as Ukraine, have restrictions in all categories. Similarly, while Ukraine has the highest corporate tax rate, Hungary offers the lowest one in the sample. More importantly for the topic of interest, we find a large variation with respect to labor market

---

<sup>14</sup> Corporate tax rates are, however, an imperfect proxy as in some cases exceptions for foreign investors may apply.

regulations. The Overall Index of Dismissal Rules range from a score of 3 (rigid labor markets) for Portugal and Ukraine to 8 (flexible) for Austria and Hungary and 11 (highly flexible) for Belgium.

## Estimation Results

### FDI Determinants

We begin by examining determinants of FDI and proceed by including one by one the five measures capturing a host country's labor market flexibility. We estimate a logit model with fixed effects for each investing company.<sup>15</sup> The results are presented in Table 3. We find a positive and significant coefficient on the host country's population size, suggesting that larger countries are more attractive investment destinations. Further, the data suggest that lower restrictions on FDI and stronger property rights protection are associated with a higher probability of FDI taking place. As anticipated, we find a negative and statistically significant coefficient on the corporate tax rate in the host country, which suggest that, all things being equal, more taxation deters FDI. The coefficient of the host country average wage is positive and significant, which is somewhat counterintuitive, yet not unusual in the literature on determinants of FDI as the average wage may be capturing the purchasing power of the population. Finally, the dummy for the host country being a transition economy is negative and significant indicating that transition countries have a lower probability of receiving FDI than what would be predicted given their economic and regulatory environment. The transition economies dummy is

---

<sup>15</sup> Note that in the fixed effect logit, firms without any investment projects drop out of the estimation.

introduced in the model to capture some common unobserved characteristics of the transition countries. Excluding it, however, would not affect the conclusions of the analysis.

We now turn our attention to the labor market variables. As higher values of these variables correspond to a more flexible labor market in the host country, we expect the estimated coefficient to be positive if greater flexibility in the host economy attracts FDI. We start with the Indices of Dismissal Rules. The first measure included is the Index of Flexibility of Individual Dismissal Procedures. Its coefficient is positive and statistically significant at the one percent level, thus suggesting that indeed, *ceteris paribus*, the more flexible the host country's labor market, the higher the probability of FDI taking place. The same conclusion is reached when the Index of Flexibility of Collective Dismissal Procedures, the Index of Notice and Severance Payment as well as the Overall Index of Rules for Dismissal are used. In all cases, the indices have positive and highly significant coefficients. We also use the GCR Index of Flexibility of Hiring and Firing Practices and again find evidence of a positive relationship between the labor market flexibility and the location choice of multinational investors. In addition, we estimate a model including all three components of the Overall Index of Dismissal Rules. We find that two of them (Severance Payment Rules and Collective Dismissal Rules) remain positive and statistically significant. Finally, we include the GCR index in addition to the three components of the Overall Index of Dismissal Rules. The Severance Payment Rules Index and the GCR index bear positive and significant coefficients. The lack of significance of the other two indices is most likely due to high correlation between various measures of labor market flexibility.

Next, we focus on explaining the determinants of FDI volume rather than the mere fact of investment taking place. We employ the Tobit specification and follow the same procedure of

consecutively adding labor market variables to the regression, keeping the same controls as before. In addition, we include some source country characteristics, such as the logarithm of the GDP per capita and the population size. We also account for the characteristics of the investing firm, in particular its size and its international experience.<sup>16</sup>

The results, presented in Table 4, confirm our previous findings that the labor market flexibility in the host country is an important factor affecting the location decision of multinational firms. When entered one at a time, all five indices of the host country labor market flexibility have the expected positive signs and are statistically significant at the one percent level. When we include all labor market flexibility measures in the same regression, all measures with the exception of the Individual Dismissal Rules Index remain positive and statistically significant. The other controls for host country characteristics have the same signs as in the fixed effects logit regressions and are highly significant. The only exception is the host country average wage, which now bears a negative and statistically significant sign in five out of seven specifications. As for investor characteristics, we find that larger firms as well as firms with greater international experience are more likely to undertake FDI. The same is true of firms headquartered in richer countries.

To test the robustness of these results and to make sure that they are not driven by the presence of transition countries, we restrict the sample to Western European economies. As before, all four labor market variables are statistically significant and bear the expected positive sign (see panels A and B of Table 5). As a further robustness check, we express the FDI volume relative to the host country GDP. As illustrated in Panel C of Table 5, the results confirm our

---

<sup>16</sup> Note that the number of observations is smaller in Tobit than in the fixed effects logit regressions due to missing observations on the investment volume.

previous findings that labor market flexibility is an important factor explaining the volume of foreign direct investment in host countries.

One may argue that FDI decisions are not driven by the labor market regulation in the host country but rather by the *difference* in the flexibility of firing and hiring between the source and the host country. For instance, a French company may have a greater incentive to engage in FDI than its British counterpart simply because French labor market regulations are more stringent than those prevailing in the U.K. Therefore, next we examine how the differences in labor market regulations between the home and the host countries influence the FDI location choice. For the purpose of consistency other variables, where the differential in the business environment between the source and the host country (rather than the absolute level) is likely to matter, enter in the relative form. These are: corporate tax rates and wage rates. We do not enter the population size in the relative form since we do believe that it should matter for FDI decisions. Similarly, we do not include relative GDP per capita as it is highly correlated with relative wage rates.

The results are presented in Table 6. As a higher value of the labor market flexibility term corresponds to more flexible host country's labor market relative to the source country (recall that  $Flexibility_{ic} = Flexibility_{host} - Flexibility_{source}$ ), we expect to obtain a positive coefficient. And indeed we find evidence that a more flexible labor market in the host country relative to the home country is associated with a higher likelihood of investment. The magnitude of the effects is economically meaningful. As the labor market flexibility in the host country (keeping the source country and other things constant) increases from the level of France (inflexible) to the level of the United Kingdom (flexible) the volume of investment goes up by between 12 and 26 percent depending on the measure employed.

As expected, we find that a differential in corporate tax rates is positively associated with the likelihood and the volume of investment. Note that to facilitate the interpretation of the results, we define the differences in tax rates and wages as those prevailing in the source country relative to those in the host (i.e.,  $Tax\ rate_{ic} = Tax\ rate_{source} - Tax\ rate_{host}$ ). On the other hand, the difference in the average wages appears to be negatively correlated with the probability of investing abroad and the investment size. However, this may not be surprising since most of the FDI originates from and is destined for rich countries that differ little in terms of wage level. All other variables have the expected signs.

The regressions presented so far constrain the effects of labor market flexibility on FDI to be equal across countries. This may be a strong assumption since the sample of host countries in our data set includes both industrial and transition economies. To relax this assumption we introduce an interaction between the labor market flexibility measures and the dummy variable for transition host countries and repeat the exercise. As illustrated in Table 7, the coefficients of the labor market differentials remain positive and highly significant in all regressions. The interaction terms with the transition dummy are negative and significant in six cases, which suggests that the relationship between the value of investment and the labor market flexibility appears to be weaker for transition countries than for the sample as a whole. In all regressions, however, the link between labor market flexibility and the value of FDI in the sample as a whole remains robust. Thus we conclude that the presence of transition economies in our sample does not drive the results.

## Robustness Checks

As an additional robustness check we also control for the quality of governance in the host country using the measure derived by Kaufmann, Kraay and Zoido-Lobaton (KKZ) and described in detail in their 1999 and 2002 publications. When constructing their measure based on data from 17 different sources, the authors assume that the available individual country ratings reflect both some true but unobserved level of governance as well as sampling variations and perception errors. The unobserved “true” level of governance can be backed out statistically (assuming a linear unobserved component specification). The resulting estimates range from  $-2.5$  to  $2.5$ , with a mean of zero and standard deviation of one. The higher the estimate, the less corrupt and better governed the country. The results, not reported here to conserve space, are robust to including the KKZ index—all labor market flexibility proxies have the expected sign and remain statistically significant.<sup>17</sup>

As yet another robustness check (not presented here), we apply the same approach to all *existing* rather than only *new* subsidiaries of the top 10,000 European companies. In the case of multiple subsidiaries being held by the same parent company in a given host country, we include only the largest investment in the sample, regardless of when the subsidiary was created. The rationale for this exercise is that multinational companies tend to respond quickly to a change in the business environment by relocating their activities to other places. As expected, we obtain results consistent with our previous findings. Labor market flexibility variables are again consistently positive and statistically significant, reinforcing our earlier results that labor market conditions are key determinants of both the location and the volume of FDI.

---

<sup>17</sup> Note that since the KKZ and the Strength of the Property Rights indices are highly correlated, we drop the latter when the KKZ variable is included.

## **Manufacturing versus Services Sectors**

If labor market flexibility indeed matters for the location choice of multinational companies, we would expect it to be of greater importance to multinationals in more labor-intensive sectors. Since services are usually more labor-intensive than manufacturing, and since our rich database includes information about the industry in which the investing company operates, we examine whether the two types of sectors respond differently to labor market regulations. To do so, we introduce an interaction between a dummy variable equal to one for services sectors and the proxies for labor market flexibility and follow the same empirical strategy as before. The results, presented in Tables 8, confirm our hypothesis. We find that the interaction terms are statistically significant and positive in all cases. That is, labor market flexibility matters more for investors in services sectors than those in manufacturing industries.

## **Conclusions**

Labor market rigidities are often cited as one of the factors multinationals take into account when deciding on a prospective host country, yet hardly any attention has been paid to this issue in the empirical literature. This paper is an attempt to further our knowledge in this area. Using firm level data on new foreign investments undertaken by European companies during the period 1998-2001 and a comprehensive set of labor market indicators, we examine the impact of labor market flexibility on FDI inflows into 19 European countries.

Our empirical findings are as follows. The FDI location choice as well as the volume of FDI are positively related to labor market flexibility in the host country and to the difference between labor market regulations in the host and the source country. That is, a more flexible

labor market in the host economy (relative to the investor's home country) is associated with a higher likelihood of investment. As expected, this effect matters more for firms operating in services sectors than for manufacturing companies.

Table 1: *Variable Definitions and Data Sources*

Variable	Definition	Source
FDI <sub>ic</sub>	Equal to 1 if a new subsidiary was created by firm <i>i</i> in country <i>c</i> during 1998-2001, and 0 otherwise	<i>Amadeus</i> database
FDI volume <sub>ic</sub>	The value of firm <i>i</i> 's investment into a new foreign subsidiary in country <i>c</i> (expressed in logarithmic form)	Own calculations based on the <i>Amadeus</i> database
Firm's size	Value of total assets in US dollars (expressed in logarithmic form)	<i>Amadeus</i> database
Firm's international experience	Number of foreign subsidiaries in 1998	<i>Amadeus</i> database
GDP per capita	Current US dollars (expressed in logarithmic form)	World Bank World Development Indicators Database
Population size	Expressed in logarithmic form	World Bank World Development Indicators Database
FDI Restrictions Index	Ranges from 0 for no restrictions to 4 for restrictions present in all areas	Wei and Schleifer (2000)
Property Rights Index	Ranges from 1 for little or no protection, to 7 for strongest protection of property rights	<i>Global Competitiveness Report 2001-2002</i>
Corporate tax rate	Expressed in percentages	PricewaterhouseCoopers
KKZ Governance Index	Ranges from -2.5 for very corrupt to 2.5 for best governed	Kaufman, Kraay and Zoido-Lobaton (2002)
GCR Index of Flexibility of Hiring and Firing Practices	Ranges from 0 for a very rigid to 7 for a very flexible labor market. Is based on equally weighted answers to the following question: -“Is hiring and firing of workers impeded by regulations or flexibly determined by employers?”	<i>Global Competitiveness Report 2001-2002</i>
Overall Index of Rules of Dismissal	Ranges from 0 for very strict to 12 for very flexible rules	Djankov et al. (2001)
Index of the Flexibility of Individual Dismissal Procedures	Ranges from 0 for very strict to 2 for very flexible rules. Is based on equally weighted answers to the following questions: -“Does the employer need to notify a third party before dismissing one redundant employee?” -“Does an employer need the approval of a third party to dismiss one redundant employee?”	Djankov et al. (2001)
Index of Flexibility of Collective Dismissal Procedures	Ranges from 0 for very strict to 5 for very flexible rules. Is based on equally weighted answers to the following questions: -“Does the employer need to notify a third party prior to collective dismissal?” -“Does the employer need the approval of a third party prior to a collective dismissal?” -“Are there laws mandating retraining or replacement prior to dismissal?” -“Are there priority rules applying to dismissal or lay-offs?” -“Are there priority rules applying to re-employment?”	Djankov et al. (2001)
Index of Notice Period and Severance Payment	Ranges from 0 for very strict to 2 for very flexible rules. Based on the sum of two scores: - the legally mandated notice period (in weeks) is above the sample median for 73 countries; - the severance pay as a number of months for which full wages are payable after covered employment of three years is above the sample median for 73 countries	Djankov et al. (2001)
Transition Country Dummy	Equal to 1 for transition countries (Bulgaria, Czech Republic, Hungary, Poland, Ukraine), and 0 otherwise.	

Table 2: *Host Country Characteristics*

# Do Payroll Tax Breaks Stimulate Formality?

## Evidence from Colombia's Reform

Adriana D. Kugler, Maurice D. Kugler and Luis O. Herrera-Prada\*

July 2017

### Abstract

Alternative work arrangements have grown rapidly around the world. In Latin America, these alternative work arrangements have long been part of the labor market and have continued to grow. The informal sector grew rapidly in Latin America over the past few decades comprising up to half of the working population in many countries. Some attribute the growth in alternative work arrangements and informality to regulations and taxes, while others argue that it is precisely the lack of enforcement of regulations that allows unprotected employment arrangements to flourish. We examine whether reducing taxes associated with employment stimulates formal sector employment. We exploit the fact that the Tax Reform introduced in Colombia in 2012 affected only certain types of workers and not others. In particular, workers earning less than 10 minimum wages (MW) and self-employed workers with more than 2 employees experienced a reduction of payroll taxes of 13.5% between 2013 and 2014. We use the Colombian Household Surveys, Social Security records and the Monthly Manufacturing Sample to conduct difference-in-difference analyses of the reform. We find evidence of increased formal employment for the affected groups after the reform using all three datasets. We find that the probability of formal employment and the likelihood of transitioning into registered employment increased for the affected groups after the reform. We also find that the level and share of permanent employment relative to temporary employment grew after the reform for those earnings less than 10 MW. The results are greatest for those in smaller firms and for those earnings close to the MW.

## 1. Introduction

Latin America and other developing regions depend on payroll taxes to finance pensions, disability and maternity benefits, and worker's compensation for those suffering from workplace injuries. In the case of Colombia, payroll taxes are also used to finance the National Vocational Training Service (*Servicio Nacional de Aprendizaje*, SENA, in Spanish) and the Colombian Institute for Family Welfare (*Instituto Colombiano de Bienestar Familiar*, ICBF, in Spanish). Until very recently, mandatory contributions in Colombia were close to the European median, where the payroll tax rate was about 40 percent (Gill et al., 2005). However, payroll contributions are much higher compared to countries with relatively less regulated labor markets, such as the United Kingdom and the United States, where contributions have fluctuated between 15 and 20 percent of total compensation (OECD, 2015).

In Latin America and continental Europe, high payroll taxes increase the labor costs that companies have to pay, thus discouraging companies from hiring workers. Nonetheless, from a theoretical perspective, the impact of payroll taxes on the labor market is ambiguous. On one hand, when workers value the benefits paid for with payroll taxes as much as the amount they contribute, increases in payroll taxes should be fully passed through from companies to employees in the form of lower salaries, with a neutral effect on unemployment. Consequently, in this case, employers would not experience increases in their overall labor costs. On the other hand, if wages are not fully flexible or if payroll taxes fund services that do not directly benefit all employees (such as SENA or ICBF), then wages would not absorb the total payroll taxes as lower wages and there would be an increase in labor costs and a reduction in employment.

Empirical studies from various countries show mixed evidence regarding the impact of payroll taxes on employment and wages. For instance, Gruber and Krueger (1991) and Gruber

(1994) find neutral effects on employment in the United States (i.e., full pass-through of taxes onto wages). Gordon (1972) also finds full pass-through taxes onto wages and no impact on employment in the United States. Nevertheless, Vroman (1974) and Harmermesh (1979) find that there is partial pass-through with non-neutral effects on wages and employment. Kaestner (1996) finds that there is no pass-through from payroll taxes onto wages for young workers in the United States.

In most Latin American countries, minimum wages are relatively high and constitute a binding restriction on formal sector employment (see, for example, Maloney et al., 2004). As a result, in this context, it is not feasible to pass-through higher payroll taxes to employees as lower wages, so it is more likely that increases in payroll taxes reduce formal employment. Gruber (1997) finds that a reduction in payroll taxes is completely passed-through to employees in the form of higher wages, without an impact on employment, in Chile. By contrast, Kugler and Kugler (2009) find that a 10 percent increase in payroll taxes reduces manufacturing employment by five percent among the least skilled workers. In this context, the increase in payroll taxes was not transferred to employees through lower wages. This finding is consistent with evidence provided by Maloney et al. (2004) that the minimum wage was binding in Colombia at the time.

In the current study, we explore the effects of the recent drop in the payroll tax rate associated with the Tax Reform, Law 1607, implemented at the end of 2012. The goal of this reform was to increase employment and, in particular, formal employment. As a result, in this study we focus on evaluating the impact of the reform on formal employment. Although the effects of changes in payroll taxes have already been studied in the Colombian context, it is important to study the effects of this particular reform for two reasons. First, the effects of changes in payroll taxes are likely to be asymmetric depending on whether there is a hike or a

decline. Due to a binding minimum wage, it is more feasible for a reduction in payroll taxes to be passed-through to employees as higher wages than for an increase in payroll taxes to be passed through to employees as lower wages. On the other hand, changes in the tax rate would have larger effects on employment if the taxes were used to finance services that do not directly benefit contributors and that, as a result, cannot be passed-through to workers' wages.

In Colombia, the link between benefits and contributions was relatively weak before the introduction of Law 1607. This made workers less willing to accept the lower wages offered by employers in response to increases in non-wage labor costs. As Kugler and Kugler (2009) show this implies that there is less formal employment and, consequently, it becomes harder to find a formal sector job. Kugler and Kugler (2009) provide evidence that reductions in payroll taxes – often proposed to stimulate demand for low-wage labor – are an effective measure to reduce unemployment and informality among young and low-skilled workers, especially if the tax cuts are focused on indirect benefits (like SENA and ICBF).

The analysis in this paper examines the effects of Law 1607, which reduced payroll taxes for those with less than 10 minimum wages and for self-employed who hired two employees or more. These are the two groups that qualify for payroll tax reductions under the reform. The analysis exploits the fact that specific groups of employers and employees were affected by the reform to estimate the impact of the reduction in the payroll tax using a quasi-experimental evaluation design. The analysis consists of comparisons of the following two pairs of groups: (i) workers with fewer and more than 10 minimum wages, before and after the reform; and (ii) self-employed workers with two or more employees, and others who either are not self-employed or who are self-employed but hire fewer than two employees, before and after the reform.

Our analysis uses three different data sets to examine the effects of the reform. In particular, we analyzed data from: the Household Surveys collected by the Colombian National Department of Statistics (*Gran Encuesta Integrada de Hogares* or GEIH, in Spanish), administrative data from the Social Security System (*Planilla Integrada de Liquidación de Aportes* or PILA, in Spanish), and survey data from the Monthly Manufacturing Sample (MMS). The data from the Household Surveys and from the Social Security records enable us to examine individual-level data to analyze effects on levels and transitions to the formal sector. The data from the MMS allow us to examine the effects of the reform on permanent employment at the establishment-level.

The results from the three data sets consistently show positive effects of the reform on formal employment. The results from the Household Surveys show an increase of 6 percentage points or a 9.5% increase in the probability of having a signed contract, and an increase of 6.8 percentage points or a 10% increase in the probability of contributing to the pension and/or health schemes for those with less than 10 minimum wages after the reform. The effects are bigger among smaller companies. Likewise, the results using Social Security records show an increase of 3.5 percentage points or 15.2% in the probability of going from informality or unemployment to formality for those paid under 10 minimum wages after the reform.

The results also show small positive effects for self-employed workers with more than three employees using both the Household Survey and Social Security data. The probability of employment and of transitioning to a job with health benefits and/or pensions increases by two and sixteen percentage points after the reform for self-employed workers with more than three employees.

The results using the Manufacturing Sample also show that the reform increased permanent employment in the manufacturing sector. The evidence shows that manufacturing establishments that pay less than 10 minimum wages on average increase their number of permanent employees by 46 workers. They also show that the percentage of permanent workers employed by those establishments increased by 10% following the reform. In general, the reform is associated with an increase in formal employment for individuals and for companies with less than 10 minimum wages after the reform. The effects are robust to different specifications and are greater among smaller companies.

## **2. Changes in the Structure of Payroll Taxes**

In 2012, Colombia introduced important legislative changes to reduce payroll taxes. The most important reform in changing payroll taxes since the reforms of the 1990s was the introduction of Law 1607. This reform reduced payroll taxes for workers with low wages, who *a priori* should have experienced greater distortions and had fewer formal job opportunities due to the higher labor costs before the reform. Payroll taxes were 29.5% in 2012, they fell to 24.5% in 2013 and reached 16% in 2014, after the tax reform was fully implemented.

A couple of years before, in 2010, the First Employment Law reduced effective payroll taxes, by allowing companies to deduct them from their income tax, for employers hiring young workers and others entering the labor force. As a result, in this analysis we try to distinguish the First Employment Law effects from those of the more expansive reforms introduced by Law 1607.

## 2.1. Law 1607 of 2013

The tax reform introduced with Law 1607 included exemptions to employer payroll taxes used to finance training programs, family and childcare programs, and compulsory health benefits. While Congress ratified the law in 2012, the exemptions were only first granted on May 1<sup>st</sup>, 2013 for contributions going to training programs (SENA, 2%) and family and childcare programs (ICBF, 3%), for a total exemption of 5% in payroll taxes. Importantly, those who contribute payroll taxes to these programs typically use neither training nor family and childcare programs. This means that the link between the benefits and contributions to the programs is weak. Beginning on January 1<sup>st</sup>, 2014, the exemptions were also applied to employer contributions to the Contributory Health Scheme (of 8.5%), first introduced in 1993 by article 204 of Law 100. In our analysis, we evaluate the differential impact on formal employment for workers exempted and not exempted from these taxes by the new law starting in 2013.

According to Law 1607, issued by decree 862 in April 26, 2013, the exemption on payroll taxes applies to two groups of individuals. First, it applies to all legal, contributing for profit entities paying taxes and that have in their payroll workers who individually accrue fewer than ten (10) monthly, legal, minimum wages. Second, it applied to all self-employed individuals who employ two or more workers. The law also indicates those individuals who do no benefit from the exemptions. Importantly, it includes all employees who earn more than 10 minimum wages and self-employed individuals who employ fewer than two employees.<sup>1</sup>

---

<sup>1</sup> Others excluded from the exemptions are legal entities that do not pay income taxes, such as unions, community action boards, horizontal joint ownership boards, those listed in articles 22, 23, 23-1, and 23-2 of the National Tax Code, legal non-profit entities, such as cooperatives, employee funds, associations, corporations, and foundations. Also excluded are those operating in Free Tax Zones established by 2012 or with pending applications at that time as well as users of previous Free Tax Zones that have qualified or could qualify in the future to these zones and that are subject to the special income tax rate of 15% established by the first subsection of article 240-1 of the National Tax Code.

At the same time, the Colombian government introduced its Plan to Increase Productivity and Employment or PIPE program (*Plan de Impulso a la Productividad y el Empleo* in Spanish), which intended to replace the revenues lost from the exemptions for SENA, ICBF and public health insurance through other sources of funding. To offset the revenue losses from the exemptions, the tax reform included an equity income tax or CREE (*Impuesto sobre la Renta para la Equidad* in Spanish). The CREE rate was 9% starting in 2013. In 2015, the CREE increased by an additional 5%, which has continued to increase by 1% every year until 2018.

The CREE percentage was distributed as follows: 1.4 percentage points go to SENA, 2.2 percentage points go to ICBF, and 4.4 percentage points go to the social security health scheme. The additional 1.2 percentage point charged during the first three years was devoted to financing public institutions of higher education (40%), the subsidized health scheme (30%), and social investments in the agricultural sector (30%). Importantly, the equity income tax is levied on profits and, thus, tends to affect the most profitable firms, which are also the largest firms.

In conclusion, beneficiaries of the payroll tax exemptions instituted by Law 1607 from 2012 are CREE contributors who hire workers with less than 10 minimum wages and self-employed individuals who hire two or more workers. The reduction of the employer payroll tax rates for SENA and ICBF by 5% and of health contributions by 8.5% introduced by the reform intends to not only reduce informal employment, but also to generate new formal jobs. The reason why employment creation in the formal sector would be incentivized is that payroll taxes, which are associated with formal employment, would fall. Even though the equity income tax was introduced, this tax is on profits and not associated with employment, thus, de-linking the new taxes from the costs associated with formal job creation.

## 2.2. Law 1429 from 2010

Before the implementation of the Tax Reform, the First Employment Law was introduced in 2010. This reform also reduced the effective labor costs generated by payroll taxes to certain types of recently hired workers. The First Employment Law allows companies to deduct from their income tax contributions the payroll tax payments destined to finance services not directly benefiting all their employees, including tax contributions to finance SENA, ICBF, as well as contributions to the Solidarity Guarantee Fund or FOSYGA (*Fondo de Solidaridad y Garantías* in Spanish), which subsidizes health services for the poorest, and the contributions to the Minimum Pension Guarantee Fund or SGP (*Sistema General de Pensiones* in Spanish) which subsidizes pensions for the poorest.<sup>2</sup> Although this law also covered pensions, the First Employment Law is more limited in the number of individuals to which it applies relative to the payroll tax reform. This is because it is only valid for new hires who are: young workers, women over 40, and earning less than 1.5 times the minimum wage, as opposed to the 10 minimum wage threshold in the 2012 tax reform.

In addition, the benefits only apply to new workers. The law defines new workers as those who appear for the first time in the administrative social security records, or those who were previously in the system identified as self-employed workers. This prevents companies from trying to claim exemptions for workers who are laid-off and rehired or new hires that are simply replacing previously hired workers.

To benefit from the deductions of Law 1429, employers must also fulfill the following requirements established by the law. Companies have to be formally registered and have to hire

---

<sup>2</sup> These deductions applied to companies that hired: workers younger than 28 years of age; female heads of households; individuals who have been displaced or are in the process of reintegration; individuals who are disabled; women older than 40 years of age, and workers earning less than 1.5 minimum wages.

the type of workers described by the law. Also, they have to increase their payrolls and not replace old personnel. That is, the number of employees must increase relative to the number of employees that were contributing in the previous year, and the total value of payroll must increase by the month of December of the previous year in which the discounts are applied.

In the empirical analysis presented in this paper, we will focus on the impacts of the Tax Reform (Law 1607) by exploiting the fact that the reform covered certain groups but not others. Moreover, we will attempt to disentangle the effects of the tax reform from those of the First Employment Law (Law 1429) since the latter preceded the tax reform and some of the coverage may have overlapped.

### **3. Data**

#### **3.1. Household Surveys**

Colombia collects cross-sectional data on labor force participation, earnings, and quality of life indicators of households since the 1960s. However, since the start of this data collection process and up to 2006, data were only available for 13 cities and their metropolitan areas. Starting in 2006, the entire survey covers 24 cities and their metropolitan areas. In addition, the modules on labor markets and household earnings also cover rural sectors.

The purpose of this data collection effort is to provide information about the size and structure of the labor force (employed, unemployed, and inactive) as well as of socio-demographic characteristics of the population. Consequently, the Household Surveys allow to classify the population according to the concepts detailed by the International Conference of Labor Statisticians (CIET, in Spanish); to calculate the main labor market indicators (participation rate, occupation rate, unemployment rate, etc.); to measure general population characteristics (characteristics of dwellings, access to public services); to obtain socio-demographic information

from the population (sex, schooling levels, civil status, etc.), and to measure employment characteristics, among others.

The existing database is the result of a probabilistic sampling of several stages, stratified by unequal conglomerates, and weighed for the 24 capital cities and their metropolitan areas. The universe is the entire civilian, non-institutionalized population residing in Colombia. The sampling unit is a segment of 10 contiguous households. The sample size is 20,669 households. The sampling error is no greater than 5% and possesses national coverage, including differentiation by zone, department, and large regions. Data were collected weekly for big cities and monthly for capital cities.

In order to construct the treatment group that was exempt because they earned less than 10 times the minimum wage, we calculated a variable called Times Minimum Wage (MW) as the ratio of nominal yearly earnings to the yearly minimum wage (515,000 Colombian pesos for 2010; 535,600 Colombian pesos for 2011; 566,700 Colombian pesos for 2012; and 589,500 Colombian pesos for 2013). We, then, used this variable to construct a dummy for 10 times the MW. We also constructed variables for self-employment, employers, and contract type for wage earners. We also construct firm size variables that identify if firms are less than 3 employees; between 4 and 10; between 10 and 50, and more than 50 employees. This allows us to construct an indicator for the second treatment group by interacting the self-employment dummy with the less than 3 employee dummy. We also created an indicator for 2013 to capture the effects of the reform by interacting the post-reform period with the indicators of whether workers earned less than 10 times the MW and whether they were self-employed and hired at least two employees.

For the dependent variables, we constructed several measures of formality. In particular, we constructed five different measures of formality: an indicator that takes the value of 1 if the

employee has a written contract and zero otherwise; an indicator that takes the value of 1 if the employer or employee contributed to social security and zero otherwise; an indicators that take the value of 1 if the employer or employee contributed either to the health system, pensions, and workers' compensation and zero otherwise.

Among the control variables, we include data on socio-economic factors about individuals, such as age, age squared, marital status, whether the person is literate (i.e., can read and write), years of schooling, department dummies, and year dummies among others.

Finally, to corroborate the robustness of the results, we create additional variables to generate placebos by replacing some criteria, and controls for the First Employment Law. In particular, we generated a variable for fewer than 20 MW, as well as variables for individuals younger than 29 years of age, women older than 40 years, and for individuals with salaries below 1.5 MW in order to control for the First Employment Law.

Table 1 shows different measures of formality for the years from 2010 to 2013. The table shows that formality has increased over time, regardless of the measure used. For example, the proportion of people who contribute to health or pension schemes or both increased from 67.7% in 2010 to 70.7% in 2013. Similarly, the proportion of people contributing to workers compensation increased from 59.2% in 2010 to 64.5% in 2013. The proportion of individuals with a written contract from 63.5% in 2010, to 66.1% in 2013. The coverage of the reform was broad, since 99.6% of workers in 2012 (the year that the reform was approved) earned less than 10 MW. Also, 16.2% of individuals were self-employed workers and 11.1% were self-employed with more than 3 employees in 2012. Finally, about half of the individuals in the sample, 50.8%, are men; about 23.2%, are married; 52.8%, have a high school degree while a minority of them has no high school in 2013.

Table 2 presents results from simple correlations between the Less than 10 MW dummy with the various measures of formality as well as individual characteristics. The table shows that those with less than 10 MW are less likely to have written contract, to have their employer make contributions to the health system and/or to a pension fund, and to have their employer make contributions to workers' compensation. This is contrary the effect we find below of a positive effect on formality after the introduction of the reform. The table also shows that those with less than 10 MW are more likely to be women, are more likely to be employed in smaller firms, and are less likely to be married. Those with less than 10 MW are also more likely to illiterate, to be high school drop outs, to be high school graduates, and to have degree a from a training college but less likely to have a University degree. This is why, below, we control for all of these characteristics in the estimations below.

### **3.2. Social Security Administrative Records**

The social security records come from the PILA, which is the data that integrates all the payroll contributions made by workers. These records contain contributors' reported information for each of the funds in which workers are required to contribute. It is the responsibility of the contributor to provide information in order for the contributions to be paid by the Social Security System.

The PILA database analyzed in this study has around 1.25 billion registries that reflect the tracking of 16.8 million individuals over 7 years (from 2008 through 2014). The data has no defined periodicity, since they are based on the contribution reports to the health and pension systems made by individuals at any point in time during the period from 2008-14. This means that a person may register more than one monthly payment to the same fund and that the number of days quoted in a month can be greater than the duration of the month.

For this analysis, we consolidated all the payment reports and quoted days for each fund in each month. The total monthly income was converted to constant December 2014 prices using the monthly inflation rate for each state.<sup>3</sup> This was then used to estimate the number of times a person earns the minimum wage. In addition, the database contains reports from the contributing company and reports related to employees. Using this code, we added individuals who reported monthly for one company and used this to infer the firm size. The database has no information regarding date of birth or age for individuals before 2014, so we did not consider these characteristics. The control variables were constructed for each month, year, type of industry, and state.

We consider workers who have a payment report as being in the formal labor market at that moment in time. Thus, we estimate transitions from non-employment to formal or registered employment as those in which an individual was not in the system the previous month and then appears as contributing into the system the next month. The results of contributions to the health and pension funds are very similar, but there is a possibility of registering payments to the health scheme without actually working. For this reason, we rely only on registries into the pension funds to identify transitions into formal employment.<sup>4</sup>

The analysis includes an unbalanced panel by individual year-month. Consequently, some of the controls in later periods do not contain any information. These are considered as additional categories in the fixed effects.

---

<sup>3</sup> There are 33 states or geographic units in Colombia. These geographic units include 26 departments, the capital city, the islands of San Andres and Providencia, and 5 territories.

<sup>4</sup> We use a randomized sample of 25% from the universe of individuals in social security records for all of our estimations. We restricted our estimations to the 25% sample due to the long computation time associated with processing the full sample.

Table 3 shows the descriptive statistics for the PILA database for the entire sample used in the analysis and by company size. The proportion of employees transitioning from outside the labor force, unemployment, or informality towards formality or the fraction of individuals who enter into registered employment is, on average, about 23% per month. The average size of registered companies in the PILA database is of 840 employees.

### **3.3. The Monthly Manufacturing Sample**

The Monthly Manufacturing Sample (MMS) includes data on employment, wages, production, and characteristics of establishments in the manufacturing sector, i.e., those with Industry Code CIIU Rev. 3.<sup>5</sup> The data of the MMS are used to detect changes that could occur in the manufacturing sector in the short-term, including changes in employment, wages, hours worked, production, and sales of Colombian manufacturing establishments. At the same time, the sample allows to determine the performance of the sector in different industrial activities; to determine the size and evolution of different sectors; to create competitiveness indices; to analyze the impact of the economic dynamics on the productive sector; and to construct an index to temporarily estimate GDP.

The accountant, manager, owner, or the person in charge of accounting matters in the establishment provides information on the establishment to DANE (the National Administrative Statistics Department). The MMS uses as sampling, observation, and analysis unit the industrial establishment and it is part of the Annual Manufacturing Sample with a 5% error rate at the national level. It includes stratified probabilistic sampling (although random for each stratum),

---

<sup>5</sup> This dataset dates back to May 1962, when the country started compiling industrial sampling data in order to build employment and wage indicators. In parallel, the country also collected data on industrial production, an effort that was stopped in 1970 when the data collection process was unified under a single system, using industrial codes based on ISIC Rev. 1. This design was in use until 1980. In 1978, the design of the sample was modified to comply with the adoption of new industrial codes, ISIC Rev. 2. This design was maintained until 1990. Towards the end of the 1990s and the beginning of the 21<sup>st</sup> century, the current design of the MMS was adopted to include changes in the representativeness of the sample and to include a third revision of the ISIC industrial codes.

and stratification is done by production, personnel, and type of industry. The compilation of the information is performed within the first 20 days of each month.

These data are subject to confidentiality restrictions and statistical reserve. Although we had access to the data through DANE's computers, it is not possible to get access to these data outside of the country. For this reason, the descriptive information we obtained from the database is limited. One of the reasons for such confidentiality is a company that meets certain characteristics (for instance, size, production, and type of industry) may be the only company in a region and, as a result, confidentiality would be lost. Confidentiality is one of the main agreements with the companies providing information.

In this study, we use the MMS to examine the impacts of the reform on employment and hours worked of different types of workers in the manufacturing sector. The data to which we had access has about 120,770 entries (about 16,400 annual entries). The database we used had information on the establishment characteristics previously mentioned as well as monthly temporary jobs from January 2007 through April 2014. Even though there is an identifying number that may seem unique, it is not possible to do a panel-like tracking because often times the response of each unit is voluntary and it is sometimes forcefully imputed because of probabilistic matters.

We constructed several variables with the MMS for analysis. Unlike the Household Surveys and the Social Security data, the MMS does not have individual level wages. We can, however, estimate the ratio of the average wage in the establishment to the MW of 515,000 in 2010 Colombian pesos. Then, we estimate a dummy variable for establishments whose average wages are less than 10 times the MW to identify establishments in which employees are most likely affected by the payroll tax reform. Our outcomes are the total number of the total number of

production and non-production permanent employees and the proportion of permanent production and non-production workers out of the total number of employees (both permanent and temporary).

The idea is that permanent employment should increase both in levels and as a proportion of total employment, since payroll taxes are required for permanent workers but largely exempt temporary workers.<sup>6</sup> We also examine the impact of the reform on the number of hours worked by permanent employees. Since the fixed cost of hiring a permanent worker goes down, employers should now prefer hiring more permanent workers and reducing their hours worked. We also construct a placebo of fewer than 20 MW, to check that our results are driven by the reform and not by some other factor that affects firms paying lower wages.<sup>7</sup>

Table 4 shows descriptive statistics for the MMS data. The average share of permanent non-production and permanent production employees in the sample are 52.2% and 99.5%, respectively. The average number of yearly regular and extraordinary hours worked for permanent non-production employees are 19,587 and 1,725, respectively.

Figure 1 shows the distribution of establishments by state. The vast majority of manufacturing establishments are in Bogota, Antioquia, and el Valle; the rest of the establishments are distributed throughout the country. Bogota, the capital of Colombia, has 32.9% of the establishments and 7.3% are located in the state of Cundinamarca (a state right next to Bogota); 21.4% are in the state of Antioquia; 12.8% are in the state of Valle; 6.3% are in the state of Atlantic (in the Caribbean coast) and 3.4% are in the state of Santander. The rest are distributed

---

<sup>6</sup> Temporary workers mostly operate under the modality of “prestación de servicios” (provision of service contracts). Under these contracts, temporary workers are hired without benefits and are not employees as such. They get their own healthcare and have to set aside 13% for income taxes to pay the “retención en la fuente” tax.

<sup>7</sup> The share with earnings above 10 MW is 0.8 percent and of those one quarter earn over 20 MW, after applying expansion factors to the sample.

throughout the country with no more than 2.5% of the establishments located in any one of the other states.

#### 4. Empirical Evidence

We explore empirically whether the reduction of payroll taxes and restructuring of taxes generated incentives to create formal jobs. We also evaluate if the reform increases employment at the extensive margin (number of employees) and reduced employment at the intensive margin (number of hours) using data at the individual-, household- and establishment-level. We use the Colombian Household Surveys, Social Security records and the Monthly Manufacturing Sample to conduct difference-in-difference (DiD) analyses of the reform.

##### 4.1 Results from the Household Surveys

We estimate the following model to calculate the probability of having a formal job using data from the Household Surveys:

$$P(F_{it}) = bX_{it} + l_s + f_r + \tau_t + \delta_0 \text{Less 10 MW}_{it} + \delta_1 \text{Post}_t \times \text{Less 10 MW}_{it} + \delta_2 \text{Post}_t \times \text{Self-Employed\_More 3 Employees}_{it} + u_{it}$$

where  $P(F_{it})$  is the probability of having formal employment and where formal employment is equal to one if the individual has a formal job defined as: (a) having a written contract, (b) the individual or employer pays for health benefits, (c) the individual or employer contributes to a pension fund, (d) the individual or employer contributes to a health and/or pension scheme, or (e) the individual or employer pays for workers' compensation.  $\text{Less 10 MW}_{it}$  is a dummy variable that equals one if the person receives fewer than 10 minimum wages (10 MW).  $\text{Self-Employed\_More 3 Employees}_{it}$  is an indicator that equals one if the employee is self-employed and hires

three or more workers.<sup>8</sup>  $Post_t$  is an indicator for whether the person is observed after 2013. Thus, the coefficients on the interaction terms,  $\delta_1$  and  $\delta_2$ , capture the effects of the reform on formal employment.  $X_{it}$  is a vector of controls that includes characteristics such as age, marital status, gender, schooling level, firm size, and an indicator for whether the employee is self-employed or not as well as interactions between this last indicator with firm size.<sup>9</sup> The sectorial, geographic, and temporal effects are captured by  $l_s$ ,  $f_r$  and  $\tau_t$ , respectively. We cluster standard errors by state.<sup>10</sup>

Table 5 reports coefficients  $\delta_1$  and  $\delta_2$ , which capture the effects of the individuals with fewer than 10 minimum wages and on self-employed with more than 3 employees.<sup>11</sup> The results show that the reform generated an increase in the probability of having formal employment. Specifically, the probability of having a written contract after the reform is 6 percentage points greater for employees with wages less than 10 MW. The probability of contributing to health benefits is 6.2 percentage points higher. The probability of contributing to a pension scheme increased by 6.9 percentage points and the probability of contributing to a health and/or pension system increases by 6.8 percentage points for workers with fewer than ten MW after the reform. Finally, the probability of contributing to workers' compensation increases by 5.7 percentage points. These coefficients are robust and are significant even with clustered standard errors. To

---

<sup>8</sup> Note that the data does not allow distinguishing 2 or more employees, so we construct a variable for three or more employees.

<sup>9</sup> Our treatment group is composed of workers earning below 10 MW and the comparison group of those with earnings above the 10 MW threshold. Since a potential concern is baseline unbalance among individuals in each group, we control for possible baseline differences in education, experience, age, race and gender, among others.

<sup>10</sup> Another potential concern is that lower wage individuals, say those earning above but close to the minimum wage may be more prone to transitioning into and out of formal employment. To explore that issue, Figure 2 presents the probability of formal employment (defined as contributing to health or pensions) as a function of the fraction of wages out of the MW in 2010. We find that this plot is roughly flat (except at low multiples of the MW), implying that the probability of being formal is not directly related to wages as multiples of the MW. Below, we perform robustness tests by leaving out of the control group those wages very close to the MW.

<sup>11</sup> As a baseline, we separate out the impact of lower payroll taxes, by first estimating a simple DiD design including only wage earners (comparing those above and below the 10 MW threshold) and then individually estimating the effect on self-employed individuals (by comparing those above and below the two workers threshold).

understand the magnitude of these effects, we estimated the elasticity of employment with respect to non-wage labor costs. The effects translate into elasticities of 0.2 and 0.22 for the effects regarding written contracts and jobs that contribute to health or pensions. These effects are in line with the effects at the lower end of the range of 0.15-0.75 reported by Hamermesh (1996).

Table 5 also reports coefficients of the post-reform indicator interacted with the indicator for self-employed workers with 3 or more employees. The results show that the probability to pay for health benefits or a pension fund increases by 1.6 and 2 percentage point among self-employed workers with more than two employees after the reform. This effect translates into an elasticity of employment of 0.07, which is about a third of the elasticity we calculated for workers with less than 10 minimum wages.<sup>12</sup>

When the effects are estimated separately for men and women, we continue to find effects for those with less than 10 minimum wages as well as effects for the self-employed with more than 3 employees for both men and women. Panel B of Table 5 shows the effects for women and Panel C for men. The results for those earnings less than 10 MW are greater for women and they are observed across all measures of formality. For example, the probability of having a written contract increases to 12.3 percentage points while the probability of contributing to either health or pension benefits increases to 10.5 percentage points for women earning more than 10 MW after the reform, which correspond to elasticities of 0.42 and 0.34 respectively. The results in Panel C shows equivalent effects on these measures of formality of 2.9 and 4.4 percentage points for men,

---

<sup>12</sup> We have also estimated the impact of the effects in separate regressions when we only include the interaction of Less than 10 MW with the reform dummy and when we only include the interaction of Self-employed with More than 3 Workers with the reform dummy. These results are reported in Appendix Tables 1 and 2. The regressions reported in Appendix Table 1 for those with Less than 10 MW are estimated only for those with positive earnings. The regressions reported in Appendix Table 2 for the Self-Employed with More than 3 Workers are estimated only for the self-employed. Since the two variables were shown not to be correlated in Table 2, it is not surprising that the results are very similar to those reported in Table 5 when both effects are included simultaneously.

which correspond to elasticities of 0.1 and 0.14 respectively. By contrast, the effects on the probability of formality on the self-employed with more than 3 employees is similar for women and men, except for the probability of having a written contract.<sup>13</sup>

Table 6 shows the results of the effects of the Tax Reform by firm size. The results show that Law 1607 had greater effects on formal employment among those working in the smallest firms. Panel A report estimates for the full sample; Panel B report estimates for those in firms with 10 or fewer employees; Panel C report results for firms between 11 and 49 employees, and Panel D report results for those in firms with 50 or more employees. The effects for those working in firms with 10 or fewer employees are larger than those for the entire sample. The probability of having a written contract and the probability of making health and pension contributions increases by about six percentage points for self-employed workers with more than 3 employees and it increases tenth-fold for those with less than 10 minimum wages. The effects for workers with less than 10 minimum wages and who work in firms with 11 to 49 employees are significant and bigger than those in the entire sample, but smaller than those found for small firms with fewer than 10 employees. Formality for those earning less than 10 minimum wages in medium-sized firms increased between 11 to 13 percentage points, but there is no effect among self-employed workers in medium-sized firms except for the pension contributions definition of formality.

By contrast, the probability of making health and pension contributions among workers earning less than 10 minimum wages in firms with 50 or more employees increased by only 1.3 percentage points after the reform, which is a much smaller effect than the one found in the full sample. The effects are, thus, bigger among those in smaller and medium size firms than for those

---

<sup>13</sup> To allow for the possibility that those closer to the MW may be much more likely to go from informality to formality, we restrict the treatment group to exclude workers close to the MW. Appendix Table A3 excludes those workers with wages that are 10% around the MW. The results are very similar to the ones reported in Table 4.

in bigger firms. This makes sense given that bigger firms were more likely to have to pay the CREE and smaller and medium size firms are more likely to have qualified for exemptions for employees closer to the MW and for self-employed hiring others.

As a check that these results capture the effects of the reform and not some other factors affecting workers after the reform, we performed regressions with placebos. In our placebo, we changed the threshold of ten MW (as specified by Law 1607) to 20 MW in order to calculate the dummy variable for employee wages. In these regressions, we excluded all workers with fewer than 10 MW. Table 7 shows these results with clustered standard errors. We found that there was no effect on formality for people with fewer than 20 MW. As can be observed on Table 7, in many cases the coefficients become negative and they were always insignificant.<sup>14</sup>

Finally, Table 8 shows similar effects to those presented in Tables 4 and 5, but controlling for effects on groups affected by the First Employment Law. In particular, we included indicators for individuals younger than 29 years of age, women older than 40, and individuals earning less than 1.5 MW and we interacted them with a post-2011 indicator, since the First Employment Law was enacted in December 2010. These results show that the effects of the interaction between the reform and employees with less than 10 MW are still positive and significant and similar in magnitude even when controlling for the First Employment Law. In this case, the probability of having a written contract and health or pension contributions increase by about 6.4 to 7 percentage points, respectively, for those earning less than 10 MW. The effects for the self-employed with more than 3 employees also remain positive and significant and of similar magnitude to those we found without controlling for the First Employment Law. The effects for

---

<sup>14</sup> Another placebo could involve examining the impact for those below 5 MW or some other threshold below the 10 MW threshold. The problem with this approach, however, is that those with less than 5 MW were indeed affected by the reform so it does not offer a true placebo.

women older than 40 years of age and for those who earn less than 1.5 MW after 2011 are neither statistically nor economically significant. On the other hand, the First Employment Law does seem to have a positive, though small, impacts on younger workers with less than 29 years of age.

In conclusion, people earning less than 10 minimum wages benefited the most from the reform in terms of having a higher likelihood of holding a formal sector job and the effects are greater for women and for workers in small firms.<sup>15</sup>

#### 4.2. Results from Social Security Records

We estimated the following model to calculate the impact of the reform on transitions from unemployment, inactivity, and informal employment into registered employment:

$$P(F_{it}) = bX_{it} + l_s + f_r + \tau_t + \mu_m + \delta_0 \text{Less 10 MW}_{it} + \delta_1 \text{Post}_t \times \text{Less 10 MW}_{it} \\ + \delta_2 \text{Post}_t \times \text{Self-employed More 3 Employees}_{it} + u_{it}$$

where  $P(F_{it})$  is the probability of transitioning from non-employment or informal employment into the formal sector.  $\text{Less 10 MW}_{it}$  and  $\text{Self-employed More 3 Employees}_{it}$  are indicators for groups exempted from the payroll tax, that is, those with less than 10 minimum wages and self-employed workers with two or more employees.  $\text{Post}_t$  is an indicator for whether the company is observed after 2013.  $X_{it}$  includes economic activity and size of the firm. The PILA database does not contain data on age, education, or any other individual characteristic. The geographic and

---

<sup>15</sup> The announcement of the Tax Reform in 2012 and its enactment in 2013 may have motivated firms and workers to agree to report earnings around the 10 MW to reduce the payroll tax burden. If this were the case, there would be bunching around the threshold. We ran a regression to check if workers were more likely to report earnings around 10 MWs around the time of the reform. Appendix Table 4 show the probability of reporting wages between 8 and 12 MWs, 8.5 and 11.5 MWs and 9 and 11 MWs. Column 1 shows a negative though very small impact of the reform on the likelihood of reporting wages between 8 and 12 MWs. Columns 2 and 3 narrow this window by looking at reported wages closer to 10 MWs. We find significant, but barely detectable, effects of one tenth of one percent on the likelihood of reporting wages between 8.5 and 11.5 and between 9 and 11 MWs, which for practical purposes we could denominate negligible.

sectorial effects are captured by  $l_s$  and  $f_r$ , respectively, and the year and month effects are captured by  $\tau_t$  and  $\mu_m$ . All of the regressions estimate clustered standard errors at the individual level.

Table 9 shows the effects on transitions into registered jobs for the full sample and by firm size. Columns (1) and (2) show the coefficients for the interaction terms in regressions using the full sample. Columns (3) and (4) show the estimates for firms with fewer than 3 employees, Columns (5) and (6) show the estimates for firms between 3-10 employees; Columns (7) and (8) show the estimates for firms between 10-50 employees and Columns (9) and (10) show the estimates for firms with more than 50 employees. The overall results in Column (1) show an increase in the probability of transitioning into formal sector employment of 3.5 percentage points among employees with less than 10 minimum wages and of 16.3 percentage points among self-employed workers employing more than 2 employees. The specification in Column (2) allows for differential effects for those earnings less than 2 MW, those earnings between 2 and 5 MW and those earning between 5 and 10 MW. As expected, these results show that the impact is greatest on those earning close to the MW and smaller for those with higher wages. The probability of transitioning into formal employment increases by 5.1 percentage points for those earning less than 2 MW, by 2 percentage points for those earning between 2-5 MW and by 1 percentage point for those earning between 5-10 MW. During the 1990s, the higher payroll taxes could not be passed on as lower wages for workers for whom the minimum wage was binding and they could not remain or become formally employed (see Kugler and Kugler, 2009). Therefore, it is likely that a reduction in payroll taxes due to the 2012 reform had the greatest impact in terms of formal employment for this group of workers.

Columns (2)-(10) of Table 9 show the effects on entry into registered jobs for firms of different sizes. Columns (3) and (5) show that the likelihood of transitioning into registered

employment increases by 39.4 and 29.7 percentage points for those in firms with fewer than 4 employees and in firms with 4 to 10 employees who earn less than 10 MW after the reform. Also, Columns (4) and (6) show that the effects are bigger for those earning less than 2 MW, somewhat smaller for those earning between 2-5 MW and even smaller, though still positive and significant, for those earning between 5 and 10 MW. The effects are negative for those in larger firms. Likewise, the likelihood of transitioning into registered employment increases by 11.7, 6 and 7.5 percentage points for self-employed workers with 4 to 10 employees, with 10-50 employees and with more than 50 employees.

### 4.3. Results from the Manufacturing Survey

We estimated the following model to calculate the impact of the reform on the level and composition of employment using the monthly manufacturing sample:

$$E_{jst} = \alpha K_{jst} + l_s + f_r + \Psi_t + \delta_0 \text{Less 10 MW}_{jst-1} + \delta_1 \text{Post}_t \times \text{Less 10 MW}_{jst-1} + v_{jst}$$

where  $E_{jst}$  is employment in establishment  $j$  for permanent production and non-production employees, as well as the percentage of permanent production and non-production employees.  $\text{Less 10 MW}_{jst-1}$  is a dummy variable that equals one if the establishment pays average wages that are less than ten minimum wages before the reform.  $\text{Post}_t$  is an indicator for whether employment at the company occurs after May 2013. The geographic, sectorial, and temporal effects are captured by  $l_s$ ,  $f_r$ , and  $\Psi_t$ .  $K_{jst}$  represents installed capital. All standard errors are clustered by state.

The coefficients of interest are those for the interaction between the variable for less than 10 minimum wages and the variable for after 2013 for the different types of workers. Panel A in Table 10 shows the results for the entire sample, while Panels B, C, D, and E in the same table show the results for establishments with up to 3 employees, 4-10 employees, 11-50 employees,

and more than 50 employees, respectively. Columns (1) and (2) in Table 10 report the impacts on the number of permanent non-production and production employees, Columns (3) and (4) reports impacts on the percent of non-permanent and permanent production workers. For establishment that pay on average less than 10 minimum wages, we observed an increase in the number of permanent workers and employees after 2013. In particular, Columns (1) and (2) in Panel A show that there is an increase of 46.2 permanent non-production employees and of 254 permanent non-production employees in establishments that pay less than 10 minimum wages after the reform. This by itself suggests increased job creation in the manufacturing sector. In addition, Columns (3) and (4) of Panel A show an increase of 10% in the share of permanent non-production employees, though no effect on the share of permanent production employees.

Columns (5) and (6) in Table 10 also show the effects on regular and extraordinary hours for all permanent workers. The results in Column (5) show substitution in working hours for permanent employees. There is a reduction of 279 regular hours or a reduction of 1.5% in regular hours for this group of workers, though no effect for extraordinary hours.

Panels B-E in Table 10 show effects by establishment size. The results show that even though the effects regarding additional permanent workers are naturally smaller in smaller establishments, the effects are clearly larger for smaller companies when looking at the shares of permanent workers. Panels B and C in Table 10 show that the percentage of permanent nonproduction employees increases by 85.8 and 55.5 percent, respectively, in establishments with fewer than 4 employees and in companies with 4 to 10 employees and that pay less than 10 minimum wages on average. Likewise, for small companies that pay less than 10 minimum wages on average, there is an increase in the percentage of permanent production workers. Also, there is a reduction in the regular and extraordinary working hours of permanent employees in

establishments with less than 4 employees and a reduction in regular hours in establishments with 4-10 employees. By contrast, Panels D and E Table 10 show that while there is a positive effect on the number of permanent non-production and production employees, there are no effects on the shares of permanent non-production and production employees or on regular and extraordinary permanent hours among bigger establishments with 10 to 50 employees and with 50 or more employees.

Thus, consistent with the data using the Household Surveys and the Social Security records, we find bigger effects on smaller employers. This is likely because the smaller employers are more likely to face higher labor costs due to their inability to pass these costs to their employees, whose wages tend to be lower. Also, the equity income tax (CREE) introduced by the 2012 Tax Reform likely had a higher incidence on larger employers.

As with the Household Surveys, we carried out regressions with a placebo group using the MMS data. Table 11 shows the results of this placebo using as a threshold 20 minimum wages on average at the establishment-level. The results show no significant effects in the regressions that use 20 MW as a threshold.

## **5. Conclusions**

The results of estimations using data from Household Surveys, the Social Security records, and the Monthly Manufacturing Sample are consistent with an increase in the creation of formal employment in response to the Tax Reform that eliminated payroll contributions for training, family services and health benefits.

In the case of regressions using data from the Household Surveys and the Social Security records, there is strong evidence indicating a greater propensity towards formality among the two

groups who experienced payroll tax reductions due to the reform, i.e., those with less than 10 MW and self-employed with more than 2 employees.

The analysis with the data from the Household Survey (GEIH) and the data from the Social Security records (PILA) show similar effects on formal employment with contributions to pension funds. The Household Survey results show an impact of 6.9 percentage points on the likelihood of being employed jobs with contributions to pension funds for those with less than 10 minimum wages. The Social Security data shows an increase of 3.5 in the likelihood of transitioning to employment registered in a pension fund. The results from the two databases also show positive effects on formal employment among self-employed workers with more than two employees. The Household Survey estimations also show an increase of 1.6 percentage point in the likelihood of being employed in a job with contributions to both health and pension plans for self-employed workers with more than 2 employees. Likewise, the Social Security data results shows an increase of 16.3 in the likelihood of transitioning into a job registered with pension contributions.

Moreover, the results using the Household Survey and Social Security record data show that small firms are the ones most likely to respond to the reform by creating formal jobs. Moreover, the results using the Social Security records are also stronger for those who earn lower salaries closer to the minimum wage. We also included placebo regressions to verify that the results were not driven by the reform and not by other factors. We do a placebos test including interactions with less than 20 MW instead of 10 MW and the results show no effects. The fact that the placebo group was not affected, and that the groups most likely to be affected are indeed the ones for which we find greater effects, confirms that the results are likely driven by the reform.

The Manufacturing Sample results confirm these results and show an increase in permanent employment. These results show an increase in the number and proportion of permanent production and non-production employees after the reform among establishments that pay less than 10 minimum wages on average. The Tax Reform also caused a substitution in the regular hours worked by permanent workers, as would be expected since the costs of hiring permanent workers decreased. As with the individual-level results, establishment-level results show that the Tax Reform had greater impact among companies with fewer than 10 employees.

These effects are larger in comparison to the reform from the mid-nineties in Colombia. Kugler and Kugler (2009) find a much smaller effect – a 10% percent increase in payroll taxes reduced employment by about 5%. The results from the MMS, which are closest to those used by Kugler and Kugler (2009), show that a decrease of 13.5% in payroll taxes introduced by the reform increased the share of permanent non-production workers by 46%.

At the same time, the effects are substantial compared to other reforms carried out in Colombia affecting both the supply and demand of labor. On the demand side, the deductions introduced by the First Employment Law for new hires from specific groups do not appear to be as effective as the exemptions introduced by the Tax Reform. On the supply side, the program Youth in Action (or Jóvenes en Acción in Spanish), which provided vocational training and internships to young individuals, increased formal employment among men and women by 6 and 7 percentage points, respectively. In this case, the cost per employee was \$770 dollars. In comparison, the tax reform probably generated fewer costs, since the funds lost due to the tax exemptions were recovered through the equity income tax. On the other hand, Kugler et al. (2015) find that the effects of the Youth in Action program were permanent. It is too early to know if the

effects of the Tax Reform are long-term, but it is possible that entering the formal sector can generate positive hysteresis and increase the probability of remaining in the formal sector.

Table 1: Descriptive Statistics for Household Survey, 2010-13

	2010	2011	2012	2013
	(1)	(2)	(3)	(4)
Employer or Employee contributes to Pension Fund	.697 (.46)	.706 (.456)	.721 (.448)	.737 (.44)
Employer or Employee contributes to Health System	.747 (.435)	.758 (.428)	.768 (.422)	.78 (.414)
Workers' Compensation	.683 (.465)	.696 (.46)	.717 (.451)	.734 (.442)
Employer or Employee contributes to Pension/Health Fund	.753 (.431)	.763 (.425)	.774 (.418)	.785 (.411)
Self-Employed	.176 (.381)	.183 (.387)	.197 (.398)	.202 (.401)
Employee	.812 (.391)	.805 (.396)	.791 (.407)	.787 (.41)
Works for the same Company that Pays	.807 (.395)	.861 (.346)	.864 (.343)	.863 (.344)
Written Contract	.716 (.451)	.721 (.449)	.729 (.444)	.742 (.437)
Self-Employed with More than 3 People Hired	.137 (.344)	.141 (.348)	.156 (.363)	.162 (.368)
Firm with less than 10 Employers	.298 (.457)	.292 (.455)	.282 (.45)	.272 (.445)
Female	.477 (.499)	.474 (.499)	.473 (.499)	.482 (.5)
Cohabitants for Less than 2 years	.031 (.173)	.033 (.179)	.036 (.186)	.036 (.187)
Cohabitants for More than 2 years	.261 (.439)	.266 (.442)	.267 (.443)	.272 (.445)
Married	.265 (.442)	.253 (.435)	.249 (.432)	.245 (.43)
Other Marital Status	.443 (.497)	.447 (.497)	.448 (.497)	.447 (.497)
Less than High School	.022 (.146)	.021 (.143)	.02 (.141)	.02 (.139)
High-School Degree	.524 (.499)	.523 (.499)	.512 (.5)	.49 (.5)
Training College Degree	.186 (.389)	.199 (.399)	.216 (.411)	.238 (.426)
University Degree or more	.268 (.443)	.257 (.437)	.252 (.434)	.252 (.434)
Illiterate	.012 (.108)	.011 (.103)	.011 (.105)	.011 (.102)
Observations	83,310	88,058	91,096	91,422

Notes: Table reports means and standard deviation of all socio-economic and work characteristic from 2010 to 2013.

Table 2: Differences in outputs and controls for those with less than 10 MW

	2010	
	More than 10 MW Mean (1)	Less than 10 MW Effect (sd) (2)
Employer or Employee contributes to Pension Fund	.958	-.212*** (.017)
Employer or Employee contributes to Health System	.986	-.194*** (.01)
Workers' Compensation	.977	-.236*** (.011)
Employer or Employee contributes to Pension/Health Fund	.994	-.196*** (.006)
Self-Employed	.106	.052** (.023)
Employee	.894	-.064*** (.023)
Works for the same Company that Pays	.952	-.168*** (.016)
Written Contract	.983	-.23*** (.01)
Self-Employed with More than 3 People Hired	.106	.02 (.023)
Firm with less than 10 Employers	.021	.241*** (.011)
Female	.244	.216*** (.034)
Cohabitants for Less than 2 years	.018	.018 (.011)
Cohabitants for More than 2 years	.077	.179*** (.02)
Married	.66	-.4*** (.038)
Other Marital Status	.245	.204*** (.034)
Less than High School	0	.023*** (.001)

Training College Degree	.046	.15*** (.015)
University Degree or more	.909	-.659*** (.021)
Illiterate	0	.009*** (0)
Observations	83,310	

Notes: Table reports the difference between treatment and control groups for all socio-economic and work characteristics from 2010 to 2013. 10 Minimum Wages without missing by report. \*\*\* p<0.01, \*\* p<0.05, \* p<0.1

Table 3: Descriptive Statistics for Social Security Records, 2008-2014

	Full Sample (1)	Firms < 3 Employees (2)	Firms 4-10 Employees (3)	Firms 11-50 Employees (4)	Firms > 50 Employees (5)
Firm Size	840.3 (4,121.2)	1.33 (0.59)	6.57 (2.05)	26.4 (11.42)	3,259.9 (7,625.3)
Average wages / Minimum wages	0.52 (1.94)	0.33 (1.24)	0.70 (1.90)	0.89 (2.11)	1.67 (3.30)
Probability of Transition from Non-employment to Employment	0.23 (0.42)	0.50 (0.54)	0.56 (0.50)	0.55 (0.50)	0.53 (0.50)
Observations	368,310,936	32,240,555	9,402,418	20,038,184	94,741,231

Notes: This table shows the mean and standard deviation in parenthesis. Full Sample estimated using a 25% randomized sample of the universe of Social Security records from January 2008 to December 2014. Firm size estimations using a 12.5% randomized sample of the universe of Social Security records from January 2008 to December 2014. Firm size is estimated as the number of people who report their payment for the same company.

Table 4: Descriptive Statistics for the Monthly Manufacturing Sample, 2007-2014

	Mean (1)
Share of Permanent Non-production Employees	52.2 (109.0)
Share of Permanent Production Employees	99.5 (171.4)
Regular Hours Permanent Non-production Employees	19587.1 (34,327.25)
Extra Hours Permanent Non-production Employees	1725.0 (4,599.4)
Salary of Permanent Non-production Employees	160799.1 (387,913.7)
Salary of Permanent Production Employees	150674.0 (307,710.6)
Observations	120,770

Notes: This table reports the mean and standard deviations in parenthesis of the share of production and non-production employees, and their regular and extraordinary hours as well as their salaries.

Table 5: Effects of the Payroll Tax Reform on Formality, Household Surveys

	Written Contract (1)	Health Contribution (2)	Pension Contribution (3)	Health and Pension Contribution (4)	Workers' Compensation (5)
Panel A. Full Sample (353,886 Observations)					
Less than 10 Minimum Wages X Reform	0.060*** (0.008)	0.062*** (0.017)	0.069*** (0.018)	0.068*** (0.014)	0.057** (0.025)
Self-employed with More than 3 Workers X Reform	0.011* (0.006)	0.019*** (0.003)	0.020*** (0.002)	0.016*** (0.003)	0.020*** (0.002)
Panel B. Women (168,589 Observations)					
Less than 10 Minimum Wages X Reform	0.123*** (0.008)	0.096*** (0.033)	0.105*** (0.034)	0.105*** (0.030)	0.086* (0.047)
Self-employed with More than 3 Workers X Reform	0.021*** (0.003)	0.023*** (0.004)	0.015*** (0.003)	0.021*** (0.004)	0.022*** (0.005)
Panel C. Men (185,297 Observations)					
Less than 10 Minimum Wages X Reform	0.029*** (0.009)	0.040*** (0.012)	0.046*** (0.012)	0.044*** (0.010)	0.038* (0.018)
Self-employed with More than 3 Workers X Reform	0.008 (0.008)	0.018*** (0.004)	0.024*** (0.004)	0.014*** (0.004)	0.021*** (0.003)

Notes: The table reports coefficients and clustered standard errors by department in parenthesis of linear probability models of different measures of formality on the interaction terms of the post-reform dummy with indicators of whether the worker earns less than 10 MW or the workers is self-employed and hires more than 3 employees. The formality measures include: a Written Contract dummy; an indicator of whether the employer or employee pay Health and Pension Contributions; an indicator of whether the employee is covered by Workers' Compensation. To estimate the share of workers paid less than 10 MW, wages (deflated to their real value at 2013 prices) were divided by the Colombian Minimum Wage of 589,500 pesos in 2013 pesos. All regressions control for age, age squared, years of education, education squared, a female dummy, dummies for marital status, the number of MW the individual earns, the worker's type, firm size, the interaction between firm size and worker type and fixed effects for industry and year. \*\*\* p<0.01, p<0.05, \*p<0.1.

Table 6: Effects of the Tax Reform on Formality by Firm Size, Household Surveys

	Written Contract (1)	Health Contribution (2)	Pension Contribution (3)	Health and Pension Contribution (4)	Workers' Compensation (5)

Notes: The table reports coefficients and clustered standard errors by department in parenthesis of linear probability models of formality on interactions of Less than 10 MW and Self-Employed who hire more than 3 Workers by firm size. The following measures of formality are used: a Written Contract Dummy; an indicator of whether the employer or employee contributes to Health and Pension funds; an indicator of whether the worker is covered by Workers' Compensation. All regressions include controls for: age, age squared, year of education, education squared, a male dummy, marital status dummy, the share of wages out of the MW, firm size, type of worker indicators and interaction of firm size with type of worker and fixed effects by industry. \*\*\* p<0.01, \*\* p<0.05, \* p<0.1.

Table 7: Placebo Effects of Less than 20 MW on Formality, Household Surveys

	Written Contract (1)	Health Contribution (2)	Pension Contribution (3)	Health and Pension Contribution (4)	Workers' Compensation (5)
Panel A. Full Sample (1,404 Observations)					
Less than 20 Minimum Wages X Reform	-0.001 (0.008)	-0.013 (0.009)	-0.013 (0.009)	-0.009 (0.011)	-0.008 (0.018)
Self-employed with More than 3 Workers X Reform	-0.005 (0.005)	0.017 (0.013)	0.030 (0.038)	0.018 (0.013)	-0.017 (0.020)

## DOES EMPLOYMENT PROTECTION REDUCE PRODUCTIVITY? EVIDENCE FROM US STATES\*

*David H. Autor, William R. Kerr and Adriana D. Kugler*

Theory predicts that mandated employment protection may reduce productivity by distorting production choices. We use the adoption of wrongful-discharge protection by state courts in the US from 1970 to 1999 to evaluate the empirical link between dismissal costs and productivity. Drawing on establishment-level data from the Census Bureau, our estimates suggest that wrongful-discharge protection reduces employment flows and firm entry rates. Moreover, plants engage in capital deepening and experience a decline in total factor productivity, indicative of altered production techniques. Evidence of strong contemporaneous growth in employment, however, leads us to view our findings as suggestive but tentative.

An extensive literature explores the impact of dismissal costs – also frequently called firing costs or employment protection – on the operation of labour markets. Beginning with the seminal work of Lazear (1990), much research has focused on assessing how dismissal costs affect employment levels. Theory suggests, however, that dismissal costs may have ambiguous effects on employment levels. Dismissal costs act as a tax on firing, which reduces dismissals but also reduces hiring. The net effect of these offsetting factors is ambiguous, at least in the short run. It is perhaps not surprising therefore that the empirical literature has found widely varying effects of dismissal costs on employment levels.

By contrast, theory makes a clear prediction about the impact of dismissal costs on the efficiency of hiring and firing. Provided that dismissal protection is not undone by Coasean bargaining, dismissal protection raises firms' adjustments costs. Consequently, firms will find it optimal not to hire workers whose short-term marginal product exceeds their market wage and will choose to retain unproductive workers whose wage exceeds their productivity (Blanchard and Portugal, 2001). These distortions in production choices unambiguously reduce worker flows. They are also likely to cause firms to substitute capital for labour and have the potential to reduce productivity by distorting production choices.

This article evaluates whether, and to what extent, the introduction of dismissal costs affects firms' production choices and, ultimately, their productivity. The source of variation in dismissal costs that we exploit is the adoption of wrongful discharge protection by US state courts from the late 1970s to the early 1990s. These common-law

\* The research in this article was conducted while the authors were Special Sworn Status researchers of the US Census Bureau at the Boston Census Research Data Center (BRDC). Support for this research from NSF grant (ITR-0427889) is gratefully acknowledged. Research results and conclusions expressed are those of the authors and do not necessarily reflect the views of the Census Bureau. This article has been screened to ensure that no confidential data are revealed. We are grateful to seminar participants at the IZA Conference on Employment Protection and Labor Markets, the Census Bureau RDC Conference, MIT, NBER Labor and Productivity Groups, SOLE, and AEA and, especially, to Daron Acemoglu, Josh Angrist, Giuseppe Bertola, Björn Brügemann, and Paul Oyer for their comments. Autor acknowledges generous support from the National Science Foundation (CAREER SES-0239538) and the Alfred P. Sloan Foundation. Kugler acknowledges support from a GEAR grant from the University of Houston.

protections against wrongful discharge generated a flood of litigation in adopting states and increased the uncertainty and potential cost of discharging workers. As has been established in prior work using both household survey data and aggregate state-level employment data, adoption of wrongful discharge laws had measurable effects on state employment levels, unemployment-to-employment flows, and the outsourcing of jobs to temporary help employers (Miles, 2000; Schanzenbach, 2003; Autor, 2003; Autor *et al.*, 2004, 2006; Kugler and Saint Paul, 2004). Yet, these aggregate effects have rarely been explored using representative microdata on firms, nor have their consequences for productivity been assessed.<sup>1</sup>

In this article, we simultaneously analyse the consequences of employment protection for establishment-level employment flows and productivity. We first test whether dismissal costs reduce employment volatility – a necessary implication of any standard non-Coasean model – both at the extensive (entry/exit) margin and intensive (within-plant) margin. We next assess whether any reduction in employment volatility is accompanied by a reduction in productivity.

Our analysis exploits detailed, comprehensive establishment-level data from two Census Bureau surveys: the Longitudinal Business Database (LBD) and the Annual Survey of Manufacturers (ASM). Sourced from US tax records and Census surveys, the LBD provides annual employment and payroll information on all US private establishments in most lines of business. The LBD is thus an exceptional resource for identifying the effects of dismissal costs on how firms adjust their labour inputs; its employment and wage records cannot, however, facilitate a further study of the concomitant adjustments of other factors of production and the consequences for productivity. We thus complement the LBD with a balanced panel of ‘ongoing’ manufacturing plants continuously surveyed by the ASM. We first demonstrate that the impact of dismissal costs on employment adjustment within this panel mirrors the LBD manufacturing universe, and then turn to the ASM’s detailed operating data (e.g., output, capital investment, employment) to study extensively the important productivity outcomes.

We find that one of the three dismissal protections adopted during this period, the Covenant of Good Faith and Fair Dealing (‘good faith’ hereafter), reduced annual employment fluctuations and the entry of new establishments in adopting states. Consistent with the apparent rise in adjustment costs, we document that firms in adopting states engaged in capital deepening, leading to a concurrent rise in labour productivity. Notably, we find evidence of a decline in total factor productivity following adoption of the good faith exception. Our effects are strongest in the short run, peaking around three years after the adoption and declining afterwards. These results suggest that adoption of dismissal protections altered short-run production choices and caused employers to retain unproductive workers, leading to a reduction in technical

<sup>1</sup> In contemporaneous work, Bird and Knopf (2005) analyse the effects of wrongful-discharge protections on the earnings, profitability and efficiency of the US banking sector from 1980 to 1990. They conclude that adoption of wrongful-discharge protections raised wages, reduced profits and lowered productivity in this sector. Petrin and Sivadasan (2006) introduce and implement a novel framework for estimating the effects of employment protection legislation on productivity, focusing on its impact on the gap between workers’ marginal revenue product and the wage. Using data from Chile, they find that increases in firing costs raise this gap. Prieger (2005) examines the impact of the Americans with Disabilities Act on the entry and exit of firms in retail.

efficiency. Clouding the interpretation of these results, however, is the finding that adoption of the good faith exception is associated with implausibly large subsequent growth in manufacturing employment. This pattern suggests that our results may be partly contaminated by confounding economic shocks. Thus, while our analysis provides novel direct evidence that employment protections may reduce firm-level productivity, the results must be viewed as tentative. It is our hope that future studies will provide further exploration of these initial results.

## 1. Wrongful Discharge Protection in the US

The US has long had a legal presumption that workers and employers may freely terminate their employment relationships ‘at will,’ that is without notification, financial penalty or requirement to demonstrate good (or any) cause. This legal doctrine, referred to as employment-at-will, was first articulated by the Tennessee Supreme Court in 1884 and was subsequently adopted into the common law by almost all US state courts by the mid-1930s (Morriss, 1994).<sup>2</sup>

Beginning in the 1970s, the legal consensus supporting employment-at-will eroded rapidly. In a series of precedent-setting cases between 1972 and 1992, the vast majority of US state courts adopted one or more common-law exceptions to the employment-at-will doctrine. These exceptions constrained the ability of employers operating in adopting states to terminate workers ‘at will.’ These common-law exceptions are typically classified into three categories:

- (1) the implied covenant of good faith and fair dealing (‘good faith’ exception);
- (2) the tort of wrongful discharge in violation of public policy (‘public policy’ exception); and
- (3) the implied-in-fact contract not to terminate without good cause (‘implied contract’ exception).<sup>3</sup>

We summarise these exceptions here and refer the reader to Autor *et al.* (2006) for an extended discussion.

Read broadly, the good faith exception prohibits employers from firing workers for ‘bad cause.’ The definition of ‘bad cause,’ however, varies greatly by state and over time. The California Court of Appeals’ famous 1980 good faith ruling in *Cleary v. American Airlines*<sup>4</sup> – probably the most influential of all good faith cases – was initially understood to bar California employers from terminating *any* worker without good cause. However, the California Supreme Court’s 1988 ruling in *Foley v. Interactive Data Corp* vastly reduced the scope of the *Cleary* decision and limited the financial remedies

<sup>2</sup> Idaho, New Jersey and New Mexico adopted employment-at-will in 1948, 1953 and 1968, respectively. Prior to Idaho, the most recent was Wyoming in 1937. Montana is the only state to have implemented exceptions to the employment-at-will doctrine by statute rather than common law (Ewing *et al.*, 2005).

<sup>3</sup> For detailed discussion of the evolution of the employment-at-will doctrine, see Morriss (1994, 1995), Autor (2003), Kugler and Saint Paul (2004) and Autor *et al.* (2006). Our discussion draws particularly on the latter work, which contains (at present) the most current legal analysis. Legal scholars, including most notably Dertouzos and Karoly (1992), also categorise these exceptions according to whether they allow for tortious damages (i.e., pain, suffering, and possibly punitive damages) in addition to contractual damages (i.e., exclusively economic losses). Recent work has not found that this distinction is empirically relevant (Autor *et al.*, 2006), however, and hence we focus on the three categories of legal exception.

<sup>4</sup> 168 Cal. Rptr. 722 (Cal. Ct. App. 1980 October).

available to plaintiffs.<sup>5</sup> At present, all eleven state courts that recognise the good faith exception (including California) primarily limit awards to 'timing' cases in which the employer intentionally terminates a worker to deprive her of a promised benefit (e.g., a sales commission or non-vested pension). Hence, 'bad cause' under the good faith exception is currently construed narrowly, though this was not always the case.

The public policy exception, recognised by 43 states as of 1999, provides workers with protections against discharges that would inhibit them from acting in accordance with public policy. In states recognising the public policy exception, workers may, for example, litigate if they are fired for performing jury duty, filing a worker's compensation claim, reporting an employer's wrongdoing, or refusing to commit perjury on behalf of the employer. Because courts typically limit public policy cases to clear violations of explicit legislative commands, rather than violations of a vaguer sense of public obligation, the public policy exception is not generally thought to impose substantial constraints on employer behaviour.

The implied contract exception, also recognised by 43 states in 1999, comes into force when an employer implicitly promises not to terminate a worker without good cause. Such implicit promises may include, for example: personnel manuals stating that the employer's policy is to terminate employees only for just cause; expectations arising from a worker's longevity of service or history of promotions and salary increases; and usual company practices that preclude terminating workers without good cause. The expected economic impact of the implied contract exception is hard to gauge. On the one hand, employers can potentially 'contract around' this exception simply by rewording personnel manuals and adding explicit language to employment contracts to state that all employees remain 'at will'.<sup>6</sup> On the other hand, firms without sophisticated human resources staff may be unaware of the implied contract exception or lack the expertise to insulate themselves fully from its reach. Additionally, the implied contract exception can potentially reclassify an employer's entire workforce as not 'at will,' which may impose significant costs.

To assess the effects of these employment-at-will exceptions on productivity and employment outcomes, we adopt a difference-in-difference approach that contrasts state-level changes in outcomes in adopting states to contemporaneous changes in outcomes in non-adopting states. This treatment-control contrast identifies the average causal effect of the exceptions on the outcomes of interest under the assumption that these outcomes would have otherwise evolved similarly in adopting and non-adopting states. We take a number of steps to buttress the robustness of this statistical approach. All econometric models include industry or industry-by-year fixed effects (in addition to state fixed effects) to absorb industry-wide shocks that may be correlated across states. In addition, most specifications include state-specific linear time trends to

<sup>5</sup> 765 P.2d 373 (Cal. 1988). Whereas the *Cleary* decision permitted plaintiffs to recover tortious damages for violations of the good faith doctrine, *Foley* reduced these damages to contractual losses (Jung and Harkness, 1989).

<sup>6</sup> And indeed, large employers took such steps. The Bureau of National Affairs (1985) found that 63% of large employers surveyed in the early 1980s had recently 'removed or changed wording in company publications to avoid any suggestion of an employment contract', and 53% had 'added wording to applications and handbooks specifying that employment may be terminated for any reason'. Sutton and Dobbin (1996) report that the percentage of firms using 'at will' clauses in employment contracts increased from 0% to 29% between 1955 and 1985.

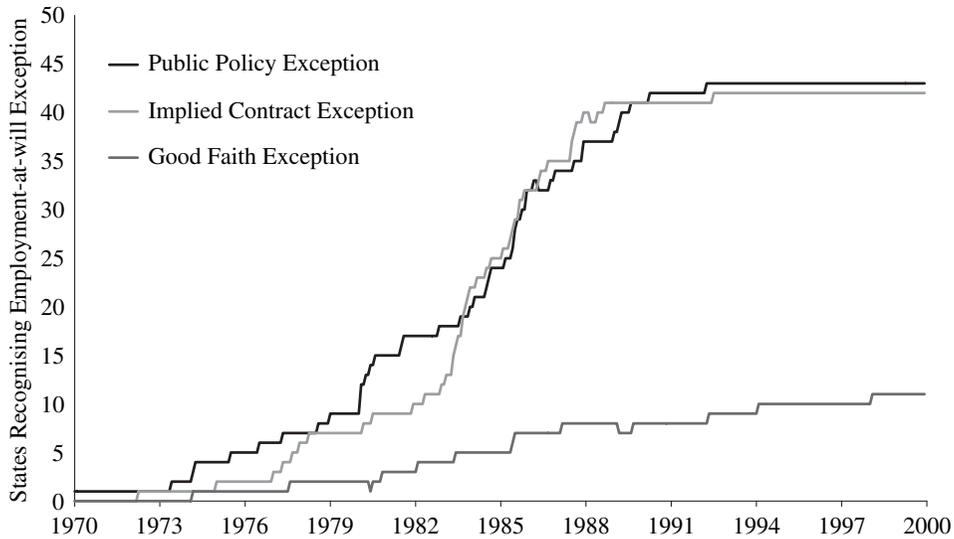

Fig. 1. *Count of States Recognising Exceptions to Employment-at-will, 1970–1999 at Monthly Frequency*

account for possible pre-existing trends that may predate the adoption of employment-at-will exceptions and could otherwise be confounded with adoption. Some specifications further include plant fixed effects, where identification comes from contrasts of within-plant changes in outcomes in adopting relative to non-adopting states. As a falsification test, we also estimate dynamic models that contrast changes in outcomes in years prior to and following adoption of exceptions to provide a check on the possibility that adoption of employment-at-will exceptions are caused by changes in outcomes rather than *vice versa*.

Figure 1 plots the number of states recognising each of the three exceptions during the time period of 1970 to 1999 (at monthly frequency).<sup>7</sup> Two main points are visible. First, the public policy and implied contract exceptions are far more widely recognised than the good faith exception. Second, adoption of each exception appears to follow something of a contagion pattern, with a large number of adoptions occurring in rapid succession between 1976 and 1988, followed by near-stasis from 1988 forward. This pattern suggests that adoptions cannot be viewed as fully independent, but that a widespread change in legal thinking in the 1970s and 1980s led many state courts to amend the long-standing doctrine of employment-at-will at around the same time. This potentially presents a challenge for identification in that businesses might react in advance to anticipated changes in the legal environment, thus blurring the pre-post contrast. However, the date at which a state adopts a given exception is an idiosyncratic function of the cases brought before state high courts and the disposition of the sitting judges. Many states never adopt exceptions and others reverse or amend these exceptions after adoption. Accordingly, precedent-setting cases that generate exceptions to employment-at-will typically will provide a discrete element of surprise. This is

<sup>7</sup> The dips in the series reflect court reversals of doctrines that were previously recognised.

particularly likely to be true for the good faith exception, which was adopted more slowly and less extensively than either the public policy or implied contract exceptions.

As emphasised by Autor *et al.* (2006), it is likely that a substantial component of the economic cost of the employment-at-will exceptions emanates from the uncertainty they introduced into the employment relationship. When most exceptions were adopted in the late 1970s to late 1980s, the volume and cost of wrongful discharge litigation that would ultimately ensue was unknown to firms and potential litigants. Adding to the uncertainty, personnel and professional law journals (i.e., the trade publications relied upon by personnel managers and corporate attorneys) published numerous articles that appeared to overstate the scope of the protections afforded to workers and the penalties that firms would incur for violating them (Edelman *et al.*, 1992). Because employers were potentially led to anticipate greater constraints and costs than ultimately materialised, Autor *et al.* (2006) argue that the short-term and medium-term effects of these dismissal protections may have exceeded their 'steady-state' effects, and they present evidence consistent with this hypothesis.

Several prior studies have analysed the effects of employment-at-will exceptions on labour market outcomes. The first study in this vein, Dertouzos and Karoly (1992), found using aggregate state-level data that adoption of common-law dismissal protections reduced state employment levels by as much as 7%. Subsequent analyses by Miles (2000), Schanzenbach (2003) and Autor *et al.* (2004, 2006) using industry-level and household-level data do not confirm these results, however. These more recent studies find either modest negative effects (Autor *et al.*, Schanzenbach) or no effects of dismissal protections on employment levels (Miles). As noted above, however, theory makes ambiguous predictions about the impact of dismissal costs on employment levels.

A number of studies also provide evidence that states' adoption of dismissal protections raised hiring and firing costs. Miles (2000) and Autor (2003) show that employers in adopting states substituted temporary help agency workers for direct-hire employees, presumably in an effort to minimise litigation risks.<sup>8</sup> Kugler and Saint-Paul (2004) find using the National Longitudinal Survey of Youth that these protections (especially the good faith exception) reduced the re-employment probability of unemployed relative to employed workers, suggesting that dismissal protections exacerbated adverse selection into non-employment. Both sets of findings are significant for our work because they demonstrate that the adoption of dismissal protections raised firms' adjustment costs – a necessary condition for them to have had productivity impacts.

Our study builds on this prior work in two major respects. First, use of establishment-level data provides direct evidence on the effects of dismissal protections on firms' employment adjustments at both the extensive (plant opening/closing) and intensive (job flows) margins. Second, we directly evaluate the consequences of dismissal protections for establishment-level production choices and realised productivity.

<sup>8</sup> The implied contract exception in particular confers a comparative advantage on temporary help agencies since these firms are universally understood to offer only short-term employment. It is the implied contract exception that appears primarily responsible for the growth of temporary help agency employment (Autor, 2003).

## 2. Theoretical Considerations

In a standard competitive model of the labour market, employment protection is economically equivalent to mandated employment benefits. Benefit mandates raise the cost of employing workers, leading to an inward shift in labour demand. If, however, workers value the mandated benefit at its marginal cost of provision – that is, the mandate is efficient – then the Coase theorem applies. Labour supply shifts outward to offset the inward shift in labour demand, employment levels are unchanged and wages fall to cover exactly the cost of the benefit (Summers, 1989; Lazear, 1990). There are no productivity or employment consequences.<sup>9</sup>

Mandatory dismissal protection can impose efficiency costs in the competitive model, however. If workers value dismissal protection at less than its marginal cost of provision – or, equivalently, if some share of the termination benefit accrues to a third-party, such as an attorney – the benefit mandate drives a wedge between the private and social cost of job separations, yielding a deadweight loss. Because dismissal costs are only paid when workers and firms separate, the deadweight loss component of the dismissal cost functions as a tax on separations – an adjustment cost. Consider, for example, a case where a worker's marginal product falls below his wage and the wage cannot drop sufficiently to compensate the firm (either due to a non-negativity constraint or due to downward wage rigidities). If the worker values the dismissal benefit at its marginal cost, both the worker and the firm will agree to terminate the job. If the payment of the dismissal benefit incurs a deadweight loss, however, both the worker and the firm will find it optimal to continue the employment relationship so long as the present value of the productivity shortfall is less than the deadweight loss. Consequently, inefficient dismissal protection – that is, protection that workers value at less than cost – inhibits efficient job separations (and, indirectly, reduces efficient accessions as well).

In the competitive model, inefficient dismissal protection unambiguously reduces allocative efficiency – that is, they are welfare reducing. Their implications for the technical efficiency of production are less clear cut. If dismissal protection causes firms to retain (some) unproductive workers, this will cause a decline in labour productivity, *ceteris paribus*. Offsetting this factor, firms may screen new hires more stringently, leading to a favourable compositional shift in the productivity of the employed workforce. Moreover, because inefficient dismissal protection provides firms with an incentive to substitute from labour to other factors of production, capital deepening may also raise the marginal product of labour. Hence, the net impact on technical efficiency (as opposed to allocative efficiency) is ambiguous.

<sup>9</sup> Aghion and Hermalin (1990) and Levine (1991) present models in which dismissal protection is under-provided by the private market due to adverse selection. Bertola (2004) also presents a model in which dismissal costs are under-provided due to risk-aversion. Agell (1999) discusses why eliminating dismissal protection may not be desirable when labour markets are subject to fairness considerations and market imperfections, while Wasmer (2006) and Macleod and Nakavachara (2007) focus on human capital investment. In all these cases, dismissal protection mandates can be efficiency-enhancing since workers may value this protection above its cost of provision. In the Coasean model, this would imply that imposing the mandate would raise employment levels. See Saint-Paul (2002) and Brügemann (2007) for theories on the political economy of employment protection.

While many labour economists use this competitive model as a benchmark, much of the macroeconomic literature views employment protection through the lens of the Diamond-Mortensen-Pissarides equilibrium unemployment model (Mortensen and Pissarides, 1994; Kugler *et al.*, 2003). As in the competitive model, dismissal costs in the equilibrium unemployment model curtail efficient separations by reducing the threshold productivity at which firms are willing to dismiss workers, thus reducing productivity. In contrast to the competitive model, however, worker-firm matches in the equilibrium unemployment setting generate quasi-rents, and the allocation of rents between firms and workers is typically determined through Nash bargaining. Nash bargaining exacerbates the deadweight loss from inefficient employment protections.<sup>10</sup> In the Nash bargain, dismissal costs reduce the firms' outside options or 'threat points,' causing workers' wage demands to rise even as profits fall. Facing lower profits and higher wage demands, firms curtail job creation and increase the threshold productivity at which they are willing to hire. The induced rise in reservation productivity potentially leads to an *increase* in firm-level productivity since less productive matches are not realised.<sup>11</sup> Hence, the net productivity effect is again ambiguous.

Although the competitive and equilibrium unemployment models differ in their details, both imply that dismissal protection dampens employment adjustments but has ambiguous effects on firms' productivity. On the other hand, both models indicate that if dismissal protection does *not* reduce job flows (perhaps because it satisfies Coasean equivalence), this protection should not affect productivity. These theoretical observations motivate our empirical approach. We begin by assessing whether adoptions of exceptions to the employment-at-will doctrine reduce job flows. We next turn to an analysis of their consequences for firm productivity. Because of the many possible avenues of adjustment noted above, our empirical work examines the impacts of dismissal protection on multiple plant-level production outcomes including capital investment, capital intensity, labour productivity and total factor productivity.

### 3. Data Description

Establishment-level data are essential for characterising how firms and their associated establishments respond to the passage of dismissal protection. This project draws such data from two confidential surveys collected by the Census Bureau – the Longitudinal Business Database (LBD) and the Annual Survey of Manufacturers (ASM). Each survey is described below, and Table 1 provides descriptive statistics.

#### 3.1. Longitudinal Business Database

The LBD is a unique source for studying employment dynamics across manufacturing and non-manufacturing sectors. Sourced from IRS tax data and Census surveys, the LBD annually covers approximately 3.9 million establishments with positive

<sup>10</sup> Nash bargaining amplifies inefficiencies because it is non-Coasean; the initial allocation of property rights affects both the distribution of resources *and* the efficiency of bargained outcomes (Grout, 1984).

<sup>11</sup> Although productivity impacts are ambiguous, welfare consequences are generally negative, as in the competitive case above. If the search equilibrium is not initially constrained efficient, however, it is possible for policy interventions to improve aggregate efficiency (Pissarides, 2000, chapter 8).

employment, representing over 68 million employees, in most US private industries. Panel (a) of Table 1 highlights that most of the LBD's surveyed employees are in the manufacturing, retail trade and services sectors. These percentages are fairly similar for states passing dismissal protections and those not doing so.<sup>12</sup>

The microdata first facilitate the development of complete state-industry-year panels of employment by summing employment counts across individual establishments. Publicly available series normally do not provide employment counts by state-industry; even when they do so, the Census Bureau is required to suppress values that compromise the confidentiality of individual establishments. Building from the microdata

<sup>12</sup> The LBD's sample frame during the 1976 to 1999 period includes mining; construction; manufacturing; wholesale trade; retail trade; and services (except hospitals, education services, social services, and private households). Sectors not included for the full panel are agriculture, forestry and fishing; transportation and public utilities; finance, insurance and real estate; and public administration. Jarmin and Miranda (2002) describe the construction of the LBD.

overcomes these limitations and a full employment panel is developed for the 1976 to 1999 sample frame.

From this state-industry-year panel, we can estimate absolute year-over-year employment changes. The mean absolute employment change over the sample is approximately 11%. This absolute job turnover metric aggregates over employment adjustments on the intensive margin (i.e., the hiring and firing of workers by continuing establishments) and the entry/exit margin. In the LBD, establishments are assigned unique and time-invariant identifiers that further afford longitudinal estimation of these two dimensions of adjustment. The entry and exit rates for establishments are approximately 13% and 11%, respectively. As many entering and exiting establishments are very small in size, only 7% and 6% of employees are working in entering or exiting establishments, respectively.<sup>13</sup> Finally, the survey's reporting structure affords the linkage of establishments to their parent firms. Approximately 22% of establishments and 55% of employees are part of multi-unit firms.

### 3.2. *Annual Survey of Manufacturers*

While the LBD provides a comprehensive view of employment dynamics across manufacturing and non-manufacturing sectors, reported data are limited to total employment and payroll only. To evaluate the impact of reduced job turnover for capital and productivity outcomes, we turn to two detailed surveys of manufacturers undertaken by the Census Bureau. The Census of Manufacturers (CM) collects operating data on all US manufacturing plants at five-year intervals (i.e., 1972, 1977, and so on). In between the CMs, the Census Bureau conducts the Annual Survey of Manufacturers (ASM). The ASM is a probability sampled subset of the CM, with the panel redrawn two years after each CM. Plants with more than 250 employees in the previous CM are sampled with certainty.

We extract from the ASM a balanced panel of all plants continuously monitored from 1972 to 1999. This restriction focuses on intensive adjustments in large plants operating in stable business climates; by conditioning on survival, the extensive margin is suppressed. While the approximately 5,700 plants represent less than 2% of all US manufacturing establishments, they account for over a quarter of total manufacturing activity in terms of employments and shipments. Almost all of these plants are part of multi-unit firms, although not all of the plants have sister establishments within this balanced panel.

Year-over-year employment changes are again studied. While the average annual employment change is again 11%, a larger fraction of these changes are negative, reflecting the trend decline in manufacturing employment from 1976 to 1999. In addition, the more detailed employment data for manufacturers allow us to examine production and non-production workers separately; the mean non-production worker employment share is 26%.

The continuous monitoring of this ASM panel affords the calculation of detailed capital stocks and productivity metrics. Capital stocks are calculated with the perpetual

<sup>13</sup> Dunne *et al.* (1989) and Kerr and Nanda (2006) provide additional descriptive statistics on entry and exit patterns in the manufacturing and non-manufacturing sectors, respectively.

2007] DOES EMPLOYMENT PROTECTION REDUCE PRODUCTIVITY? F199

inventory method, as explained below. The mean plant-level capital stock for the 1976 to 1999 sample is \$31m in 1999 dollars. Labour productivity is defined as deflated total value of shipments divided by total plant employment. Finally, we estimate total factor productivity (TFP) as the residual from a production function of value-added on four factors: production workers, non-production workers, machinery capital, and structures capital.

#### 4. Consequences of Employment Protection

In this Section we discuss the impact of wrongful discharge protections on firm behaviour. We begin by examining the first-order effect of employment protection on employment fluctuations, both at the intensive (within-establishment) and extensive (entry/exit) margins. If wrongful discharge protections increase adjustment costs, this should lead to a reduction in hiring and dismissals, resulting in an overall dampening of employment fluctuations. We next test the impact of employment protection on employment levels, a margin along which prior research has obtained mixed results. Finally, we turn to the important question of whether the possibly restricted ability of businesses to adjust employment due to the introduction of employment protections has productivity consequences.

##### 4.1. Effects on Employment Fluctuations

We estimate the effects of the wrongful discharge exceptions (i.e., good faith, public policy and implied contract) described in Section 1 on employment fluctuations using both the LBD and ASM. We begin by estimating the following equation using the LBD:

$$ABS_{sjt} = \lambda_s + \kappa_j + \tau_t + \beta_{GF}GF_{st-1} + \beta_{PP}PP_{st-1} + \beta_{IC}IC_{st-1} + \varepsilon_{sjt}, \quad (1)$$

where  $ABS_{sjt}$  is the absolute year-to-year employment change of a two-digit SIC sector  $j$ , in state  $s$ , at time  $t$ ,

$$ABS_{sjt} = \frac{|E_{sjt} - E_{sjt-1}|}{(E_{sjt} + E_{sjt-1})/2}.$$

$\lambda_s$ ,  $\kappa_j$  and  $\tau_t$  are vectors of state, industry and time effects, respectively.<sup>14</sup>  $GF_{st-1}$ ,  $PP_{st-1}$  and  $IC_{st-1}$  are indicators of whether the good faith, public policy and implied contract exceptions were in place in state  $s$  at time  $t - 1$ .<sup>15</sup> Thus, the coefficients  $\beta_{GF}$ ,  $\beta_{PP}$  and  $\beta_{IC}$  capture the effects of employment protection on annual net employment flows.<sup>16</sup>

<sup>14</sup>  $ABS$  is closely linked to Davis *et al.*'s (1996) job reallocation measure estimated at the sector level, which adds the average positive changes in employment in a sector to the average negative changes in employment in a sector.  $ABS$  is defined to be zero if both employments are zero.  $ABS$  is bounded between  $[0, 2]$ , thereby minimising the influence of outliers.

<sup>15</sup> The one-year lag from the survey date is due to employment counts in the LBD and ASM usually being measured as of March 1st.

<sup>16</sup> In addition to the  $ABS$  measure, we estimated models that distinguish between positive and negative adjustments. Since we were unable to reject the hypothesis that the results are symmetric on both margins, we suppress tabulation of these results.

*Notes:* Huber-White robust standard errors clustered on state reported in parentheses.

Our core battery of specifications also includes two estimations of greater stringency. First, we consider models with state-specific time trends. These require that identification come from the discontinuity surrounding the passage of the wrongful discharge exception. These specifications can provide reassurance that our coefficients are not reflecting smoothly trending omitted variables that are potentially correlated with the adoption of the exceptions. A benefit of the state-industry panel is that we can also control for industry-specific trends using the non-parametric form of two-digit SIC industry and year interactions. These latter estimations allow us to control for employment shifts due to national trends in a state's industries, again providing confidence in the identification strategy.

Panels (a) and (b) of Table 2 report estimates of the effects of the wrongful discharge exceptions on employment fluctuations for the Full Sample and for manufacturing only. Panel (a) includes all LBD sectors: manufacturing, mining, construction, wholesale trade, retail trade and services. The reported standard errors account for possible error correlations across firms within a state and within states over time. We weight the samples using the mean employment level in the state-industry-year cells during the early 1976 to 1985 period. The results for the Full Sample show a decline in employment fluctuations following the introduction of the good faith exception, though the results are not statistically significant. By contrast, the results for the public policy and implied contract exceptions show insignificant positive impacts on employment fluctuations.

When we estimate these models for manufacturing alone in Panel (b), we find a negative, and in the majority of cases, significant, effect of the good faith exception on employment fluctuations. This result is robust to the inclusion of state-specific and industry-specific trends. It suggests a reduction in employment fluctuations of 5% to

2007] DOES EMPLOYMENT PROTECTION REDUCE PRODUCTIVITY? F201

12% after the introduction of the good faith exception (i.e., dividing the  $-0.006$  to  $-0.016$  coefficients by the average annual employment change of 13% in Table 1 for states adopting the good faith exception). The results for the implied contract exception remains insignificant. Surprisingly, we find a positive and significant impact of the public policy doctrine on employment fluctuations in the LBD data. This latter result, however, is not supported in the upcoming analysis of the more accurate, establishment-level ASM panel.

The initial LBD analysis suggests a significant effect of the good faith exception on employment fluctuations in manufacturing. To test whether this finding is consistent with a causal relationship, we evaluate the relationship between the adoption of the good faith exception and employment fluctuations using a dynamic specification:

$$\begin{aligned}
 ABS_{ijt} = & \lambda_s + \kappa_j + \tau_t + \sum_{q=-5}^2 \beta_{GFt+q} \Delta GF_{st+q} + \sum_{q=-5}^2 \beta_{PPt+q} \Delta PP_{st+q} + \sum_{q=-5}^2 \beta_{ICt+q} \Delta IC_{st+q} \\
 & + \beta_{GFt-6} GF_{st-6} + \beta_{PPt-6} PP_{st-6} + \beta_{ICt-6} IC_{st-6} + \varepsilon_{ijt}, \quad (2)
 \end{aligned}$$

where  $\Delta GF_{st+q}$ ,  $\Delta PP_{st+q}$  and  $\Delta IC_{st+q}$  indicate whether adoption occurred at year  $t + q$ . These dynamic variables capture the transitory effects of the reforms.  $GF_{st-6}$ ,  $PP_{st-6}$  and  $IC_{st-6}$  estimate long-term outcomes by indicating adoptions that occurred at year  $t - 6$  or before. These coefficients are relative to the period three years prior to the reform, and their pattern indicates whether the earlier pre-post results (1) are consistent with a causal interpretation. In particular, we would be concerned if there are large and statistically significant coefficients on the lead indicators, regardless of whether they are positive or negative. The specification also helps identify whether the largest impacts of the exceptions occur over the short run or long run.<sup>17</sup> To conserve space, we only tabulate coefficients for the good faith exception, with full results for the public policy and implied contract exceptions given in the companion working paper version of this article (Autor *et al.*, 2007).

Appendix Table 1 presents results from this dynamic specification estimated for the manufacturing sector, as well as additional specifications including state-specific and industry-specific trends. The basic specification shows negative coefficients for the good faith lags but mostly insignificant and weakly positive coefficients for the leads, thus supporting a causal interpretation of our results. That is, the introduction of the exception precedes employment changes and not *vice versa*. By contrast, the public policy and implied contract leads and lags have typically positive coefficients, as is shown in Appendix Table 1 of Autor *et al.* (2007). The pattern for the public policy doctrine is particularly noteworthy since it suggests that the unexpected positive estimate for the impact of this doctrine on employment fluctuations found in Table 2 is likely to be spurious. These patterns are robust to the inclusion of state-specific and industry-specific trends. The results using the LBD suggest that the impact of the good faith doctrine peaks approximately three years following adoption and that the long-

<sup>17</sup> The dynamic estimation also includes a second set of lead and lag variables to account for the four cases in which legal exceptions were formally abandoned. The inclusion or exclusion of these additional regressors does not materially influence the reported results.

Notes: Huber-White robust standard errors clustered on state reported in parentheses.

term effect is insignificant (i.e., six or more years following adoption). This pattern is comparable to Autor *et al.* (2006), who report that the near-term effects of adoption of wrongful discharge doctrines dissipate within approximately five years, perhaps because the initial market uncertainty about the potentially vast – but ultimately modest scope – of the protection offered is resolved (Edelman *et al.*, 1992).<sup>18</sup>

Table 2's results from the LBD suggest that manufacturing was particularly affected by the introduction of wrongful discharge exceptions, likely because manufacturing employment is highly seasonal and highly cyclical, making dismissal protections particularly costly.<sup>19</sup> We use plant-level data from the ASM to further examine the effects of employment protection in manufacturing. Panel (a) of Table 3 presents analogous results to those using the LBD in Table 2. Because our ASM sample uses a balanced panel of ongoing plants, we can now add plant fixed effects to the prior specification, leading to the following estimating equation:

$$ABS_{pt} = \mu_p + \tau_t + \beta_{GF} GF_{st-1} + \beta_{PP} PP_{st-1} + \beta_{IC} IC_{st-1} + \varepsilon_{pt}. \quad (3)$$

The dependent variable is the absolute year-to-year employment change in plant  $p$  from  $t - 1$  to  $t$ ;  $\mu_p$  is a plant fixed effect. As before, we include state-specific and industry-

<sup>18</sup> Only 13 states introduced good faith exceptions during the period studied. California introduced the first good faith exception in a highly visible court ruling. Though our basic and dynamic LBD results on employment changes are strongest for the full sample of states, the results are qualitatively similar but less precise when California is excluded.

<sup>19</sup> The mean year-to-year turnover in manufacturing was 12%, compared to 10% in construction, 6% in wholesale trade, 7% in retail trade, and 8% in services. Only mining had a higher annual turnover (27%). Regressions examining the mining sector also find a substantial dampening of annual employment volatility following the adoption of the good faith exception.

specific trends. The estimated standard errors again allow for error correlations across plants within states and within states over time.<sup>20</sup>

Consistent with the LBD, the results using the ASM suggest that the good faith exception reduces employment fluctuations. We do not find evidence, however, in the ASM sample that the implied contract or public policy doctrines impact employment fluctuations. We estimate in Table 3 that the good faith exception reduces employment fluctuations by 1.5% to 4.5%, which is about half the size of the estimate using the LBD data. While this finding is only marginally statistically significant, supporting evidence from dynamic specifications below suggest that the effect is likely to be causal.

The difference between the LBD and ASM results is explained in part by the fact that in the ASM we can control for additional unobservable factors affecting a plant's employment fluctuations. Contrasting Columns (4) and (6), with and without plant fixed effects, we can see that excluding plant effects using our ASM sample implies a reduction of 5% in employment fluctuations as opposed to 2% with plant effects. As is shown in the next Sections, the remaining differences between the estimates in the LBD and the ASM samples are likely due to the fact that the LBD includes entering and exiting business while the ASM sample is composed of a balanced sample of ongoing plants. The ASM analysis therefore excludes any effect of wrongful discharge protections on employment fluctuations occurring through entry and exit.

As with the LBD, we also estimate a dynamic specification using ASM data. Panel (a) of Appendix Table 2 presents these estimates. Similar to the patterns found with the LBD, leads of the good faith exception are found to have weakly positive and insignificant effects on employment fluctuations while lags of the good faith exception have negative effects on employment changes. The maximum dampening is again attained three years following adoption. As with the LBD estimates, the long-term impacts are insignificant and, in the case of the ASM, weakly positive.<sup>21</sup>

Since employment protection may also affect seasonal employment fluctuations (Wolfers, 2005), we also study a *quarterly* employment churn measure to complement the year-over-year changes. In particular, we estimate (3) using as a dependent variable the following measure of quarterly churn for production workers:<sup>22</sup>

$$PWChurn_{pt} = \frac{PW_{pt}^{\max} - PW_{pt}^{\min}}{(PW_{pt}^{\max} + PW_{pt}^{\min})/2},$$

where  $PW_{pt}^{\max}$  and  $PW_{pt}^{\min}$  are the maximum and the minimum quarterly production-worker employment in plant  $p$  in year  $t$ , respectively. As before we allow for state-specific and industry-specific trends and cluster the standard errors on state.

<sup>20</sup> We have also estimated analogous models using an unbalanced panel of ASM plants (i.e., not limited to those continually operating). Findings from these models, which are qualitatively similar, are available from the authors on request.

<sup>21</sup> As for the LBD results, the ASM findings are qualitatively similar but somewhat less precise when we exclude California from our sample. As a complement to the panel estimations, similar results are found with lagged dependent variable specifications that test for mean reversion.

<sup>22</sup> The ASM does not collect quarterly employment for non-production workers. The plant-level ASM does not allow us to estimate employment effects separately by demographic group, as is feasible with data from household surveys as in Kahn (2007).

Panel (b) of Table 3 shows results for these specifications. Estimates without state trends show negative effects of the good faith exception on seasonal adjustments of production workers, but the results are not significant and the effects become positive when controlling for state trends. Looking deeper, however, the results from the underlying dynamic specifications reported in Panel (b) of Appendix Table 2 consistently show weakly positive coefficients on the leads and negative coefficients on the lags. Moreover, the dampening is again most significant three years after the adoption. Thus, the dynamic specifications appear most consistent with a significant causal effect of the good faith exception on seasonal employment fluctuations over the short-run to medium-run.

#### 4.2. *Effects on Entry and Exit*

The difference in the magnitudes of the estimated effects of wrongful discharge exceptions on employment fluctuations in the LBD and the ASM samples suggests that part of the reduction in employment fluctuations observed following adoption of the good faith exception is explained by changes in firm entry and exit (i.e., the extensive employment margin). To evaluate the importance of external adjustment, we use the LBD to estimate regressions similar to (1), where the dependent variable is the log of the average count of plants over five-year intervals among continuing, entering and exiting businesses. We use five-year averages to minimise the possibility of capturing spurious entry and exit due to 'ghosting' and reporting bumps observed surrounding Census years. The wrongful discharge indicators take the value of one if the exceptions had been adopted as of the midpoint of the five-year intervals.<sup>23</sup>

Panels (a)–(d) of Table 4 report results of these regressions for total, continuing, entering and exiting plants, respectively. Panel (a) shows little change in the total count of plants in response to the introduction of any of the exceptions. However, Panels (b)–(d) show that in the case of the good faith exception, this reflects countervailing forces among continuing and other plants. Panel (b) shows an increase in plant survival after the introduction of good faith exceptions, though this effect is only marginally significant. Panel (c) shows that entry is substantially reduced in manufacturing after the introduction of good faith exceptions, though exit is unaffected. These results, controlling for state-specific and industry-specific trends, suggest a reduction of 7.7 log points in the number of entering plants, where log points refer to 100 times the coefficient in the log-linear specification (thus roughly corresponding to percentage point changes).<sup>24</sup> This translates into a reduction of about 9,000 establishments. By contrast, the public policy and implied contract exceptions do not appear to affect entry.

<sup>23</sup> Annual regressions of entry and exit yield quantitatively similar results, though the magnitudes are smaller. Studying entry and exit at five-year intervals avoids spurious peaks of entry and exit rates surrounding Census years, when additional manpower is devoted to updating the business registry. This updating has a noticeable effect on establishment counts but not on summed employment levels used for year-to-year employment changes. Entry and exit are defined as the first and last year an establishment is observed in the LBD, respectively, with the end years of the sample excluded. Establishments alive for a single year are recorded as both entering and exiting. This procedure ignores potential exit and re-entry by establishments, but more importantly avoids spurious entry and exit from 'ghosting' establishments with poor longitudinal linkages.

<sup>24</sup> This result is consistent with Kugler and Pica (forthcoming), who find that increased dismissal costs in Italy after the 1990 labour market reform reduced entry of small firms.

Notes: Five-year blocks. Huber-White robust standard errors clustered on state-year reported in parentheses.

In combination with the findings in Tables 2 and 3, these results suggest that the dampening effect of the good faith exception on employment fluctuations operates through two channels: a reduction in net employment flows in ongoing plants and a reduction in the entry of new plants. The reduced rate of establishment creation helps reconcile the smaller decline in employment fluctuations evident in the ASM panel compared to the LBD.<sup>25</sup>

#### 4.3. *Effects on Employment Levels*

Here we explore the effects of wrongful discharge exceptions on employment levels. As discussed, the effect of these dismissal protections on net employment is theoretically ambiguous (at least in the short run) since both dismissals and hiring are affected.

<sup>25</sup> See Koeniger and Prat (2007) for analysis of product market regulation and the extensive margin.

*Notes:* Huber-White robust standard errors clustered on state reported in parentheses.

We start by estimating similar regressions to (3) using the ASM data, but where the dependent variable is the log of employment in plant  $p$  at time  $t$ . Table 5 presents results of these regressions for total employment as well as for production and non-production employment separately. Panel (a) shows that total employment increases with the introduction of the good faith and public policy exceptions, though the public policy results are insignificant. The implied contract exception has a negative though insignificant effect on employment, which is consistent in sign and magnitude – though not statistical significance – with the findings in Autor *et al.* (2004, 2006).

When employment is disaggregated into production and non-production workers, we find that the increase in total employment following the introduction of the good faith exception is driven primarily by the increase in employment of non-production workers. For example, the final columns of Panels (b) and (c) suggest that production employment does not react to the introduction of the good faith exception while non-production employment in the typical plant increases by 4.8 log points following the introduction of this exception.<sup>26</sup> This differential rise in non-production demand may be explained by capital–skill complementarity (Griliches, 1969; Berman *et al.*, 1994), as

<sup>26</sup> These results are robust to various specifications and to the exclusion of California and Arizona, even though Arizona had unusually high employment growth during the 1980s and 1990s.

Section 4 will show, the adoption of the good faith exception may have spurred capital-deepening in firms.

As before we also estimate dynamic specifications to test whether our findings are consistent with a causal interpretation. In these specifications, found in Appendix Table 2 of our working paper (Autor *et al.*, 2007), the estimated impact of the good faith exception on employment levels commences a year prior to adoption and becomes puzzlingly large in subsequent years when state-specific trends are included, exceeding 10 log points six years ahead. This pattern is very unlikely to reflect a causal relationship and suggests the presence of confounding shocks. A potential explanation is that California and Arizona, the two largest states that adopted a good faith exception, experienced unusually strong employment growth in the late 1980s, likely for reasons unrelated to this particular legal doctrine.<sup>27</sup> The results for the public policy exception have inconsistent signs across specifications and show no evidence of a trend break after adoption of the doctrine. By contrast, results for the implied contract exception show consistently negative effects for both leads and lags, though the lead effects are smaller.

Table 6 shows results from regressions similar to (1) using LBD data, but where the dependent variable is the log of average manufacturing employment in state  $s$  and industry  $j$  over five-year intervals and where the wrongful discharge indicators take the value of one if the exceptions had been adopted as of the midpoint of the five-year intervals. Panel (a) presents results for all plants, while Panels (b)–(d) present results for continuing, entering and exiting plants, respectively.<sup>28</sup>

Consistent with the results from the ASM, which includes only continuing plants, we find that total employment in the LBD sample increased by about 7.8 log points following the adoption the good faith exception. Examining employment separately for continuing, entering and exiting plants in Panels (b)–(d) shows that this growth is driven by continuing plants. Panel (b) shows a significant increase in employment of 8.3 log points in continuing plants, while Panels (c) and (d) show a marginal decline in employment created by plant entry and an increase in employment lost due to plant exit, although these two effects are not statistically significant. Note also the close comparability of the estimated effects of the good faith exception on employment levels in the ASM sample (Table 5, (a)) and on employment levels in ongoing plants in the LBD (Table 6, (b)). This pattern is expected since the ASM sample is composed exclusively of ongoing plants. In summary, the net growth of employment that we observe after adoption of the good faith exception is accounted for by reduced job creation in entering plants and increased job destruction in exiting plans – both of which led to reduced employment – accompanied by more than offsetting employment growth in ongoing plants.

As with the ASM, dynamic specifications (found in Appendix Table 3 of our companion working paper) show positive coefficients on the good faith exception's leads

<sup>27</sup> In fact, excluding California from the estimates largely eliminates the estimated positive employment effects of the good faith exception. However, California is arguably the strongest test-case for evaluating the labour market impact of this exception since the *Cleary* decision is *the* landmark case among good faith rulings. We are accordingly reluctant to remove California from the sample. Excluding Arizona reduces but does not eliminate the estimated positive employment effect.

<sup>28</sup> Annual employment regressions yield quantitatively similar results, though the magnitudes of the coefficients are smaller. We use employment at five-year intervals here to keep consistency with the results on the counts of entering and exiting plants presented in the previous Section.

and implausibly large positive coefficients on the lags, making questionable a causal interpretation of the effects on employment. The results for the public policy and implied contract doctrines are comparable to the prior estimates.<sup>29</sup>

#### 4.4. *Effects on Productivity*

The finding that the good faith exception reduces job flows is consistent with the expectation that this discharge protection raises firms' adjustments costs. Here we explore the consequences of this rise in adjustment costs on other margins of non-labour adjustment. One such margin is capital substitution; if discharge protections

<sup>29</sup> Table 6 also shows economically large, although inconsistent, effects of the public policy exception on employment levels. Similar to earlier studies, this pattern raises puzzles about the interpretation between the public policy exception and employment.

raise the effective price of labour by making it more expensive to hire and fire, firms may substitute towards other inputs. Second, given the restrictions on firms' ability to adjust, we also may expect total factor productivity to be affected – though as noted in Section (2), compositional shifts in worker hiring following the adoption of dismissal protections may generate countervailing effects on labour productivity.

We begin by examining whether productivity was affected by employment protections due to changes in input composition. In particular, we ask whether the introduction of employment protections affected capital investment and, subsequently, capital–labour ratios. Panels (a) and (b) of Table 7 report results of specifications similar to (1) and (3) without and with state-specific and industry-specific trends but where the dependent variables are the log of total capital investment and the log of the capital–labour ratio.

Capital stocks are measured at the beginning-of-year and constructed using the perpetual inventory method. Capital stocks are separately calculated for machinery and structures and then aggregated for total capital metrics. The capital stock of plant  $p$  in industry  $j$  at time  $t$  is:

$$K_{pt} = (1 - \delta_{jt-1})K_{pt-1} + \frac{I_{pt-1}^N}{P_{jt-1}^N} + \frac{I_{pt-1}^U}{P_{jt-3}^N},$$

where initial capital stocks in 1972 are obtained by deflating book values of capital by BEA two-digit SIC deflators for installed capital. New equipment investments,  $I_{pt-1}^N$ , are deflated with NBER four-digit SIC new-capital deflators,  $P_{jt-1}^N$ . Used equipment purchases,  $I_{pt-1}^U$ , employ the NBER four-digit SIC deflators lagged three periods. The annual depreciation rates,  $\delta_{jt-1}$ , are obtained from the BEA by two-digit SIC industries.

Notes: Huber-White robust standard errors clustered on state reported in parentheses.

Panel (a) of Table 7 shows a positive and significant effect of the introduction of the good faith exception on total investment (machinery and structures) of 6.5 log points (Column 6) but show no effects from the introduction of the public policy and implied contract exceptions. Dynamic specifications, found in Appendix Table 4 of the companion working paper, indicate that capital investment peaks several years after adoption of the good faith exception and then declines somewhat thereafter (a pattern similar to the results for employment fluctuations). However, leads of the good faith adoption variable in the dynamic specifications are notably negative (though statistically insignificant), suggesting that part of the post-adoption rise in capital investment may reflect an investment rebound from an earlier downturn.

Not surprisingly given the increase in employment levels, Panel (b) of Table 7 shows mixed – albeit generally positive – effects of the good faith exception on capital-labour ratios. For example, estimated effects are negative when controlling for state-specific trends but become positive when controlling for plant effects. Dynamic specifications, given in Appendix Table 5 of the working paper, find negative coefficients on both leads and lags, raising the question of whether the introduction of the good faith exception followed rather than preceded increases in the capital-labour ratio.

To explore effects on productivity, Panel (a) of Table 8 presents results of specifications like (1) and (3), but where the dependent variables is a TFP measure estimated using a production function residual methodology. For the residuals methodology, we

TFP is the establishment-level residual from a regression of value-added on four factors of production (production employment, non-production employment, machinery capital and structures capital) at the industry-year level.

first estimate the following production function in logs for each two-digit SIC industry and year using ordinary least squares:

$$\log(Y_{pt}) = \alpha + \zeta_{jt} \log(L_{pt}) + \gamma_{jt} \log(H_{pt}) + \theta_{jt}^M \log(K_{pt}^M) + \theta_{jt}^S \log(K_{pt}^S) + \xi_{pt},$$

where  $Y_{pt}$  is value added (i.e., total value of shipments net of materials/fuels costs and inventory adjustments) in plant  $p$  at time  $t$  deflated using the NBER four-digit SIC shipments deflators,  $L_{pt}$  is the count of production or unskilled workers, and  $H_{pt}$  is the count of non-production or skilled workers.  $K_{pt}^M$  and  $K_{pt}^S$  are the separated machinery and structures capital stocks, respectively. The residuals from the regression above provide our TFP measure:

$$TFP_{pt} = \log(Y_{pt}) - \hat{\zeta}_{jt} \log(L_{pt}) - \hat{\gamma}_{jt} \log(H_{pt}) - \hat{\theta}_{jt}^M \log(K_{pt}^M) - \hat{\theta}_{jt}^S \log(K_{pt}^S) - \alpha.$$

The results in Table 8 show a uniformly negative and generally significant effect of the introduction of the good faith exception on TFP, though the effect is slightly attenuated when we control for plant effects. By contrast, the public policy exception appears to have a positive effect and the implied contract exception appears to have a negative effect, though neither is significant in any specification.<sup>30</sup> However, results from dynamic specifications, found in Appendix Table 3, show mostly negative coefficients for both leads and lags of the good faith exception, though the coefficients on the lags are substantially larger. The dynamic specification thus raises some question about a causal interpretation of the good faith effects on productivity, though the available evidence is mostly consistent with a reduction in TFP in the four years following adoption of the good faith exception.

Finally, Panel (b) of Table 8 explores whether the increase in capital investment following the introduction of the good faith exception found in Table 7 affected labour productivity. We estimate that labour productivity rose substantially (by 1 to 4 log points) following adoption of the good faith exception. This measured rise in labour productivity follows from the fact that both capital investment and non-production worker employment (Tables 5 and 7) rose after adoption of the good faith exception. Since our labour productivity measure does not adjust for the quality of labour inputs, the rise in raw labour productivity is likely to reflect a mixture of capital deepening and compositional shifts in labour quality. Thus, this finding is not at odds with the conclusion that the good faith exception reduced TFP. Results from dynamic specifications for labour productivity that control for plant effects (Appendix Table 7 of the working paper) show negative coefficients on the leads and positive though

<sup>30</sup> We also examined a cost-shares methodology to analyse TFP. Cost shares were estimated for three-digit SIC industries from the NBER productivity database (Bartelsman and Gray, 1996). Production worker, non-production worker, and materials and fuels cost shares are calculated relative to TVS; the cost share of capital is a residual such that the cost shares sum to one. The results of the TFP measure obtained using a cost-shares methodology are generally declining but more mixed. However, the cost-shares methodology presents several disadvantages:

- (1) the coefficients on the shares are out-of-sample estimates obtained using NBER data;
- (2) we cannot disaggregate between equipment and structures since the capital share is obtained as a residual; and
- (3) the cost-shares methodology assumes constant returns-to-scale in the production function and perfectly competitive input markets.

insignificant coefficients on the lags, suggesting that the good faith exception preceded the increase in labour productivity.

## 5. Conclusions

This article makes two contributions. The first is to exploit microdata to examine the effect of dismissal protection on establishment-level outcomes in a representative sample of employers. The second is to consider simultaneously the effects of this protection on job flows — where there are unambiguous theoretical implications — and on several other important (and mostly unstudied) margins of firm behaviour, including capital investment, labour productivity and total factor productivity, where the predictions of theory are less clear cut. We believe that the power of the analysis derives from the evidence that the adoption of one particular dismissal protection, the good faith exception to employment-at-will, reduced employment fluctuations in adopting states. These effects were largest in the first three years following adoption and diminished thereafter. This finding indicates that adjustment costs rose in the short run, a necessary condition for there to be an impact on economic efficiency.

The finding on employment fluctuations motivates us to analyse how this short-run rise in adjustment costs impacted firms' choices of capital and labour inputs, and ultimately, their productivity. The most surprising result of our analysis is that the increase in adjustment costs appears to have spurred capital and skill deepening — that is, firms raised capital investment and increased non-production worker employment. These changes in input choices led to a rise in measured (non-quality-adjusted) labour productivity and a decline in total factor productivity. This last finding is potentially quite important because, if correct, it provides confirmation that exogenous increases in adjustment costs reduce efficiency.

Our findings also present two unresolved puzzles. First, the adoption of the good faith exception appears to follow (likely by coincidence) a major investment downturn. This pattern reduces our confidence in the causal interpretation of the rise in capital investment following adoption of the good faith exception. The second puzzle is that the estimated positive effect of the good faith exception on employment levels is larger than appears plausible (albeit often imprecisely estimated). In light of these puzzles, we view our findings as suggestive but inconclusive. Though our data support the hypothesis that adoption of the good faith exception raises adjustment costs, the anomalous results for employment levels suggests a cautious interpretation of the findings until further evidence accumulates.

Our results have interesting parallels with those of a recent study by Acemoglu and Finkelstein (2005) of firm-level responses to changes in labour costs in the US hospital industry. Responding to a change in Medicare reimbursement policy in the 1980s that effectively increased the cost of labour relative to capital, Acemoglu and Finkelstein document that hospitals raised both their capital-labour ratios and the skill composition of their workforces. Acemoglu and Finkelstein suggest that this result may be explained by either capital-skill complementarity or technology-skill complementarity (assuming that new capital investments embed recent technologies), as in our discussion above. While the Acemoglu and Finkelstein findings are drawn from a distinctly different economic context than our study (i.e., a heavily regulated sector versus a

2007] DOES EMPLOYMENT PROTECTION REDUCE PRODUCTIVITY? F213

relatively competitive sector) and exploit a different source of policy variation (i.e., employment subsidies rather than dismissal costs), the parallels with our findings for the effect of dismissal protection on the US manufacturing sector are nonetheless intriguing and deserving of further consideration.

## ABSTRACT

### Does Employment Protection Reduce the Demand for Unskilled Labor?\*

Perhaps it does. We propose a model in which workers with little education or in the tails of the age distribution – the inexperienced and the old – have more chance of job failure (mismatch). Recruits' average education should then increase and the standard deviation of starting age decrease when strict employment protection raises hiring and firing costs. We test the model using annual distributions of recruits' characteristics from a 1975-95 panel of plants in Belgium, the Netherlands, Italy, the UK and the US. The model's predictions are supported using the Blanchard-Wolfers index of employment protection as well as our alternative index.

## 1. Introduction

This paper presents a model of the impact of employment protection legislation on the demand for unskilled labor, which we then test using data from a panel of firms. The model relies on lack of information on the part of firms about worker characteristics. This lack of information, combined with a posited greater likelihood of “failure” on the job of unskilled workers, makes firms choosy about hiring unskilled workers when employment protection laws raise dismissal costs. Acemoglu and Angrist (2001) first put forward this type of model to analyze the impact of disability discrimination legislation on the demand for disabled workers. The model provides a rationale for why employment protection *matters more* for less skilled workers<sup>1</sup>. The paper is therefore primarily concerned with the distribution of employment opportunities rather than overall employment levels.

Our concern with distributional issues follows the changing emphasis in the literature. The literature on labor demand began by taking a homogeneous labor assumption (starting with Nickell, 1986, then developed for example by Bentolila and Saint-Paul, 1994, and more recently by Blanchard and Wolfers, 2000). Such an assumption rules out looking for the differential impact of employment protection laws across skill groups. However, evidence has begun to mount that employment protection laws impact adversely on young workers (Scarpetta, 1996) and the long-term unemployed (OECD, 1999; Nickell and Layard, 1999, 3063), even if the majority workforce are little affected. A series of papers by Kahn (2000), Jimeno and Rodriguez-Palenzuela (2002), and Bertola et al (2004) analyzing 20-30 year panels of OECD country data find that young workers and older workers, particularly males, fare less well in high unionization and employment protection environments. Moreover, Modesto (2004) has provided a formal treatment of how youth and old-age unemployment may increase with employment protection legislation, particularly if wages are inflexible – or even increase due to increased insider power of incumbent workers. Our paper offers an empirical contribution to this debate, using firm-level data.

Our model emphasizes the inflexibility caused by employment protection law rather than that resulting from union bargaining (emphasised in Kahn, 2000, and Bertola et al, 2004). According to our management informants, union density within the firms had generally been stable over time; hence this factor can be taken as a fixed effect. In the empirical work, we control for union density at the national level, and for movements in average manufacturing wages (to pick up the pressure of national collective agreements). Whether our emphasis is appropriate can be tested on an empirical basis. In fact, as will be seen, our predictions for the employment protection variable are generally borne out.

The firms in our dataset have subsidiaries both in highly regulated countries such as Italy and Belgium, and less regulated countries such as the UK and US. Figure 1 contrasts the labor environments in two of these countries, Italy and the UK. There are striking differences in job opportunities for the unskilled worker categories such as the under 25s and the over 60s. As can be seen, the 20-24 unemployment rate in Italy is around 30%. This figure is three times that in the UK, despite Italy’s large training and subsidized work programs (bottom row). Correspondingly, the 20-24 employment/population rate in Italy is currently only about 40% and falling, while that in the UK is around 70%. Similarly, at the other end of the age

---

<sup>1</sup> In a similar vein, Koeniger et al (2004), put forward a model in which employment protection reduces the firm’s outside option, so permitting unions to negotiate higher wages. Higher employment protection costs for unskilled than skilled workers should then mean that strict employment protection helps unions to reduce the skilled/unskilled wage differential – which they find. Our model provides a rationale for higher employment protection costs for unskilled workers.

spectrum, among over 60s, Italy offers few jobs, with an employment/population ratio of only 20%, compared to the UK's 35% (and a US figure of 45%). Admittedly, Italian over-60s might be content not to work – their low unemployment rate indicates little search for work, and Italy has large state-funded early retirement programs (OECD, 1996, 208). But the marked lack of jobs for older workers still needs explanation. The labor market in Italy evidently works well for prime-age groups, but not for others. This type of relatively uneven performance is the motivation for our paper.

Our use of firm-level data to test for employment protection effects is a form of “insider econometrics”, to use Ichniowski and Shaw's (2003) term. We use fieldwork interviews to generate a detailed understanding of recruitment in four multinationals with subsidiaries in the US and several European countries (see Daniel and Siebert (2003) and Morton and Siebert (2001) for similar cross-country company comparisons). This fieldwork is combined with detailed econometric hypothesis testing using the firm-level datasets we assemble. In particular, by tracking these firms over approximately a 20-year period we gain both time and country variation, which allows a fixed effects econometric framework to hold unobservables constant. The more usual aggregate country comparisons have problems of consistently defining employment and unemployment (for a survey, see Addison and Teixeira, 2003). Here, our data on recruits' characteristics are perhaps more consistent across countries, since age and education are easier to define and measure, and company personnel records form a common statistical source.

A study such as ours has to face the difficulties of measuring the force of employment protection legislation (on which, see Bertola et al, 2000). Further, we desire a time-varying measure. A well-known recent measure is that constructed by Blanchard and Wolfers (2000), based on the OECD's (1999) scoring of the strictness of employment protection legislation in member countries. We begin with this measure, as do Bertola et al (2004) and Koeniger et al (2004). However, sensitivity tests need to be conducted. For these tests, we have elected to use our own measure, which has been constructed independently of Blanchard and Wolfers, and uses somewhat different assumptions<sup>2</sup>.

To preview our results, we find that strict employment protection – both on the Blanchard-Wolfers measure and on ours – is associated both with higher average education and with less dispersion in the starting age of recruits. We interpret these results to mean that firms become choosier about hiring from the less educated as well as the young and old age groups, who are more of a risk than prime-age workers, when employment protection raises dismissal costs. The latter result might underlie the UK's comparatively healthy age dispersion of jobs shown in Table 1.

Our plan is as follows. In the next section, we present the model of labor demand, and discuss the econometric specification. In the third section, we discuss our data. In the fourth section we present the regression estimates. The final section offers a summary and conclusions.

---

<sup>2</sup> There is also a time-varying measure of the strictness of employment protection legislation based on employer views (Di Tella and McCulloch, 2004), but this series is short, 1984-1990. Alternatively, there is a series on product market regulation (Nicoletti and Scarpetta, 2003) – which is related to labor regulation but, of course, is not the same.

## 2. The Model

Theory. We analyze the demand for unskilled and skilled production labor (excluding management grades). We proxy ‘skill’ by two characteristics: the starting age of recruits,  $A$ , and the education of recruits,  $E$ . These are the characteristics for which data is consistently available from personnel records in our study plants. We do not have data on the firms’ capital stock, and it is simplest to assume that capital stock differences are predetermined, and absorbed into the firm fixed effect.<sup>3</sup>

Let us begin with a revenue function,  $R$ , which we define as price,  $p$ , multiplied by efficiency units of labor,  $\ell$ . Hence total revenue is  $R = p \ell$ . We assume that efficiency units of labor are linearly related to the number of workers,  $L$ , multiplied by a worker efficiency function  $g(A, E)$ , as follows:

$$\ell = Lg(A, E) \tag{1}$$

with  $g_A \gg 0$ ,  $g_{AA} < 0$ ,  $g_E > 0$ ,  $g_{EE} < 0$ , and  $g_{AE} > 0$  (to allow substitution between  $A$  and  $E$ ).

Let us explain our assumptions for the efficiency function, taking first the starting age ( $A$ ) argument. We make the efficiency of labor an inverted-U function of recruits’ starting age. Our reasoning is that young recruits (under 25) have less experience, and hence can be expected to be less skilful, given education. Older recruits (over 55) also have disadvantages, perhaps out-of-date skills or negative selection, in that an older worker looking for a job may have proved unsatisfactory in previous work. It is thus possible to have “too much experience”. This assumption is motivated by the fall-off in employment/population rates for older workers shown in Table 1 – but, in any case, it is generally accepted that most firms do not hire older workers (for discussion, see Heywood et al, 1999). The worker efficiency function, measured in product price ( $p$ ) terms, is given in Figure 1, with  $g_A$  starting  $> 0$ , and becoming  $< 0$ , and with  $g_{AA} < 0$ . Admittedly, careful hiring and training procedures within the company can reduce the curvature of the  $g$  function, at a cost. Also, in some cases, for example in firms which emphasize training, the curvature will perhaps be more pronounced because older workers are less trainable. All we need for our argument is some degree of curvature, so that there is a starting age range which the firm prefers as in Figure 1.

As for the role of education in the efficiency function, the efficiency of labor obviously increases with education, though at a decreasing rate, as shown in Figure 2. Again, as with starting age, the impact of education on worker efficiency will depend on the firm’s hiring and training expenditures, which we set to one side for the moment.

Consider next the element of labor force adjustment: quits, dismissals, layoffs (redundancies), and hires. To simplify, we assume the firm is in a steady state with  $L_t = L_{t-1}$ , so there are no layoffs, and the hiring rate,  $h$ , just balances the quit rate,  $\delta$ , plus the dismissal rate,  $\theta$ , i.e.:

$$h = \delta + \theta \tag{2}$$

Dismissals are central to our model. All workers face some probability of failing, and hence of dismissal. Failure can be thought of as stemming from mismatch between the worker and the job. However, since more is known about skilled workers – who are better

---

<sup>3</sup> Admittedly, an increase in capital usage over time, in response to employment protection, could also account for recruitment of more skilled workers. Our empirical findings for the employment protection variable would then simply have to be interpreted as reduced forms.

educated and prime-age – their probability of failure is lower. Hence, dismissal rates should be lower for skilled than unskilled workers. Accordingly, we make the dismissal rate a function of  $A$  and  $E$ , i.e.:  $\theta = \theta(A, E)$ . We assume  $\theta$  follows a U-shape, being least during the prime age range, so  $\theta_A > 0$  and  $\theta_{AA} < 0$ . On the other hand  $\theta_E < 0$  because the more educated have a lower failure probability.

Dismissals bring firing costs,  $F$ , and expected firing costs are  $\theta F$ . We will assume  $F$  is the same throughout the production worker group, whether skilled or unskilled. ( $F$  costs would, of course, be higher for management grades but these are not included in our study.) Since unskilled workers are more likely to be dismissed, their expected firing costs will therefore be greater than those of skilled workers, and employment protection legislation will increase such costs more for unskilled workers.

Hiring costs,  $H$ , are also relevant. Hiring and firing costs tend to move together, because firing costs bring ‘shadow’ hiring costs (Bentolila and Bertola, 1990, 391). Thus, as it becomes more difficult to fire workers, more must be invested in hiring costs – choosing the appropriate worker. This effect is likely to be greater for unskilled workers, who are untried workers without a track record, once employment protection legislation makes it difficult to substitute an unsuitable worker with a suitable one (Saint-Paul and Kugler, 2000, 8). In other words, strict employment protection raises the possibility that a job can become permanently filled by a sub-standard worker. This possibility imposes an opportunity cost on the firm: the lost value of the option of filling the vacancy with an able worker. This type of expected opportunity cost must be higher for untried candidates without track records or qualifications.

In practice, therefore, we can think of employment protection legislation as increasing the expected sum of hiring and firing costs,  $\theta V = \theta(H+F)$ . The dashed lines in Figures 1 and 2 show worker efficiency net of expected hiring and firing costs. Employment protection legislation will increase the divergence between the two lines by increasing  $V$ .

Finally, wages will also be a function of  $A$  and  $E$ , i.e.  $w = w(A, E)$ . The wage function need not be the same as the worker efficiency function, though the two will be related. Obviously, wages increase with education, so  $w_E > 0$ . However, equity considerations, or trade union pressures, are likely to prevent much variation of wages with recruits’ starting age, hence for simplicity, we assume  $w_A = 0$ . For simplicity, we have made wages independent of  $V$  – though as Modesto (2004) and Koeniger et al (2004) point out, higher  $V$  could be associated with higher  $w$  since protection of incumbent workers raises their bargaining power. We will return to this subject below.

The firm aims to choose  $L$ ,  $A$ , and  $E$  to maximize the present value of profits,  $N$ , defined as the value of output minus wage, hiring and firing costs. We write the objective function as follows:

$$N = \sum_{t=0}^{\infty} \beta^t [pL_t g(A_t, E_t) - w(A_t, E_t)L_t - F\theta(A_{t-1}, E_{t-1})L_{t-1} - H(\delta + \theta(A_{t-1}, E_{t-1}))L_{t-1}] \quad (3)$$

where  $\beta = (1 + r)^{-1}$  is the discount factor with  $r =$  discount rate, and  $p =$  product price. We assume  $L_0 = 0$ . The third term in square brackets gives total firing costs which depend on the number of workers dismissed last period,  $\theta(A_{t-1}, E_{t-1})L_{t-1}$  times  $F$ . The fourth term gives hiring

costs, which depend on the quit and dismissal rates (substituting from equation (2) above) times  $H$ .

We derive the first order conditions for equation (3) following Acemoglu and Angrist (2001, 922), with firms immediately adjusting to steady state employment levels, so  $L_t = L$ ,  $A_t = A$ , and  $E_t = E$  every period. We also assume that it takes a year for any  $H$  or  $F$  costs to arise. We can then simplify (3):

$$N = pLg(A,E) - w(A,E)L + \frac{\beta}{1-\beta} [pLg(A,E) - w(A,E)L - F\theta(A,E)L - H(\delta + \theta(A,E))L] \quad (4)$$

since  $\sum_{t=1}^{\infty} \beta^t = \beta/(1-\beta)$ . Differentiating (4) with respect to  $L$  gives:

$\partial N/\partial L = (pg(A,E) - w(A,E))/(1-\beta) - [F\theta(A,E) + H(\delta + \theta(A,E))]\beta/(1-\beta) = 0$ , so the employment level chosen satisfies the condition:

$$pg(A,E) = w(A,E) + \beta[F\theta(A,E) + H(\delta + \theta(A,E))] \quad (5)$$

As can be seen,  $L$  drops out of this condition, because of the linear form we have given the revenue function. The conditions for  $A$  and  $E$ , given below, are therefore in per-worker terms, with  $L$  determined outside the model.

For the age choice, we have:

$$\partial N/\partial A = L(pg_A - w_A) + \frac{\beta}{1-\beta} L(pg_A - w_A - \theta_A V) = 0, \text{ where } V = F + H.$$

Hence,  $pg_A = w_A + \beta\theta_A V$ . (6)

In other words, the marginal revenue product of labor by starting age must equal the “full” marginal cost of labor by age, including expected hiring and firing costs. In terms of Figure 1, where we have chosen a simple flat wage-age line, the choice of starting age,  $A^*$ , is given by the maximum of dotted  $pg(A, \bar{E}) - \beta\theta V$  line.

There is a similar condition which the optimum education choice,  $E^*$ , must meet:

$$pg_E = w_E + \beta\theta_E V. \quad (7)$$

Figure 2 illustrates the position.

It is also necessary to consider the possibility of substitution between education and starting age, as shown in Figure 3. The positively sloped section of the isoquant indicates the region where starting age is too high, reducing worker efficiency. The firm will always aim to operate to the left of this point, the “ridge line” – though in practice the line will not be well defined, since the worker age-efficiency function in Figure 1 will have a broad top. With no employment protection, cost minimization requires the factor combination indicated by point  $X$ .

Now let us consider the impact of employment protection – higher  $V$  costs – on selection of worker characteristics. From (6) we see that  $V$  can increase or decrease the marginal cost of older workers, depending upon whether  $\theta_A$  is  $< 0$  or  $> 0$  (see Appendix 1). But since  $\theta_A$  is likely to be small, we would not expect employment protection legislation to much affect the average starting age that management selects – though there may be some fall since education substitutes for age, and education is likely to increase, see below. However, strict employment protection legislation will reduce the dispersion of starting ages. This effect can be seen most simply from Figure 1. Raising  $V$  increases the curvature of the

dotted pg  $(A, \bar{E}) - \beta\theta V$  line. With a low  $V$ , the line is not very curved, so the firm will be indifferent about  $A$ , because the penalty associated with worker failure due to choice of the wrong starting age,  $\theta_A$ , will be low. Now suppose  $V$  increases. When this happens, it will become more important for the firm to ‘get it right’, that is, to choose specifically the prime age group for which  $\theta V$  is lowest. Thus, high  $V$  should reduce the dispersion of  $A$ .

The position is different for education, in equation (7). Here, we see that an increase in  $V$  lowers the marginal cost of a more educated worker, because  $\theta_E$  is negative (Appendix 1). Stricter employment protection legislation should therefore unambiguously tilt management decisions in favor of more educated recruits. Consequently we predict an increase in recruits’ average education as  $V$  increases. Moreover, as Figure 3 shows, an increase in  $V$  is likely to make the full cost of education cheaper relative to starting age, leading to substitution of education for starting age, and a movement from  $X$  to  $Y$ . At the same time, unlike the case for starting age, there is no reason to expect increases in  $V$  to reduce the dispersion of recruits’ education. Dispersion depends on the penalty associated with making the wrong education choice, which in turn depends on the curvature of the  $g$ ,  $\theta$  and  $w$  functions. However, the curvature of these functions does not depend upon  $V$ .

Our predictions for the impact of employment protection legislation on our two characteristics,  $A$  and  $E$ , thus form an interesting contrast. Strict employment protection legislation (high  $V$ ) should leave the average  $A$  of recruits undisturbed, but lower the dispersion of  $A$ . Exactly the converse should be true of  $E$ .

Admittedly, in deriving these results we have adopted certain simplifications. In particular we have ignored the possible countervailing impact of high  $V$  in raising worker efficiency – in particular, the possibility of an  $H$  argument in the  $g(A, E, H)$  function. In other words, greater hiring expenditures,  $H$ , could so stimulate (via better choice) the productivity of uneducated workers as to offset the costs associated with their higher probability of failure. However, it is implausible that such a full offset should occur. If it did, why did not management choose higher  $H$  in the first place, without being forced by employment protection legislation? In any case, we subject the matter to test below.

Specification. We form the observations for the average and dispersion of recruits’ starting age and education as follows. The analysis relates to male recruits whose contracts become permanent/open-ended within a year at the plant, since our best continuous data series relate to this group. For each of the eleven plants in each year (the plants are described in more detail below), we calculate the mean and the standard deviation of recruits’ starting age and education. The data points thus represent average behavior for each plant in each year.

This method reduces the data on some 2,400 recruitment events to approximately 140 plant-time data points, depending upon missing values. We use arithmetic weights in our estimation procedures, with weights based on the number underlying each plant’s distribution in that year, to allow for the fact that sometimes the number hired in a year is small.

Our statistical model in its general form is:

$$Q_{it} = \sum_{i=1}^{10} a_i + \sum_{i=1}^{10} b_i t + \sum_{i=1}^{10} c_i EPL_{it-1} + \sum_{i=1}^{10} d_i X_{it-1} + e_{it} \quad (8)$$

Where  $Q_{it}$  = the average or standard deviation of recruits' education or age in the  $i$ -th plant in the  $t$ -th year,  $i = 1, 2, \dots, 10$ ,  $t$  = time trend;  $a_i$  = constant term for the  $i$ -th plant;  $EPL_{it} =$

employment protection index in the  $i$ -th plant's country and  $t$ -th year;  $X_{it}$  = a vector of other controls;  $e_{it}$  = the error term. This model is completely unrestricted, with different coefficients for each plant. We then use F-tests to test whether it is permissible to restrict some or all of the coefficients to equality. This F-test procedure can be used to test whether, for example, the coefficients of the UK plants as a group can be restricted to equality – or whether some other grouping is permissible, for example, of sister-plants.

A restricted form of equation (8) is

$$Q_{it} = \sum_{i=1}^{10} a_i + bt + cEPL_{it-1} + dX_{it-1} + e_{it} \quad (9)$$

This is the basic fixed effects form, with only the constant fixed effect term,  $a_i$ , differing among plants, all other coefficients being the same. F-tests generally show that we can accept the restrictions implicit in (9).

In equation (9), the fixed effects,  $a_i$ , are meant to account for omitted variables specific to the firms, but which are constant over time. For example, plants in richer countries such as the US should have access to a supply of better-educated workers, which will obviously affect hiring decisions. By contrast, the time trend variable,  $t$ , is intended to capture effects specific to each time period, and the same across firms. An example of such effects is the reduction in unskilled labor demand such as might result from international trade competition and/or skilled-labor-using technical progress, to which all our plants have presumably been subject.

A further point is the simultaneity of starting age and education. Education and starting age will tend to be substitutes, at least when younger workers are hired. (The standard deviations of starting age and education are simpler – we can take these variables to be independent of each other, and also of the average values of starting age and education.) In fact, as we shall see, the system seems to be recursive<sup>4</sup>. First, the firm chooses recruits' education independently of starting age. Then, second, the firm chooses starting age dependent on education, and the two turn out to be good substitutes. To address this issue, we use simultaneous equations techniques to estimate the average age and average education equations.

#### Measuring employment protection.

As we have already noted, it is difficult to capture a many-dimensional force such as employment protection in a single time-varying variable (Bertola et al, 2000). Firing costs are influenced by many rules governing unfair dismissal, layoffs for economic reasons, severance payments, minimum notice periods, administrative authorization for dismissals, and prior discussion with representatives of unions or labor market administrations. In addition, for the US in particular, there is judge-made law raising the costs of dismissal (Autor, 2003), even though there are weak statutory provisions.

Nevertheless, some progress has been made. Specifically, Blanchard and Wolfers (2000) have constructed cardinal measures of the strictness of employment protection legislation for several countries; including the ones we are interested in here. Their measure is based on the OECD's country rankings of strictness of employment protection in the 1980s

---

<sup>4</sup> A recursive model may be consistently estimated using equation-by-equation ordinary least squares (Greene, 2003, 397), but not if the covariance matrix of the equation disturbances is non-diagonal, as appears to be the case for some of our specifications.

and 1990s (OECD, 1999). They then use the index developed by Lazear (1990), who quantified firing costs as the amount of severance and notice period measured in monthly wages owed to a dismissed worker after 10 years of service, to stretch the series back to the 1970s.

The resulting index for our time period is shown in Figure 4. As can be seen, it ignores possible increasing US case-law strictness of protection. It also ignores the UK's decrease in strictness under Thatcher's Conservative administration. However, on the good side, the index aims at a cardinal measure of dismissal costs (it does not simply rank countries), it covers the countries and the time periods we need, and it is independent of our own data calculations. Therefore, we use this index (as have Bertola et al (2004) and Koeniger et al (2004)) as a foundation.

We will also subject the results to sensitivity tests, and in particular demonstrate results using our alternative index of employment protection. Our index is based on somewhat different assumptions to the Blanchard-Wolfers index. It is also based on the OECD (1999) method, but for our US states, it incorporates both changes in legislation, and in relevant court practices. For the US, exceptions from the employment-at-will doctrine introduced in the majority of US states throughout the past two decades may increase employment protection – not via legislation but rather the threat of potentially costly litigation – which we have calibrated using the Rand study on termination litigation in California (Dertouzos et al., 1988).<sup>5</sup>

The resulting index is shown in Figure 5. The marked difference between the two indices in the treatment of the US can be seen. Our index gives strictness of employment protection at the state level, and also shows an increase of employment protection based on case law, while the Blanchard-Wolfers index does not. There are other detail differences as well. Thus, allowing for country fixed effects, our index only explains 0.46 of the Blanchard and Wolfers index, so the two indices are reasonably different.

The controls. Let us now turn to the control variables,  $X$ . In the first place, our plants produce four different products, and we may expect these to have different requirements for high skilled relative to low skilled workers. The plant fixed effect term helps to control for this factor. In addition, our plants can be formed into groups producing the same product (as subsidiaries of the same multinational), which allows further control.

A wage variable is also needed. Although in the development of our model we abstracted from wage effects, wages may rise if employment protection shelters incumbent workers, and so unions push up their wages (e.g., see Modesto, 2004). Since it is unskilled workers who are at risk, a measure of wage compression would be best, but this variable is not available over time. Hence, we simply include the average hourly manufacturing wage. Increases in this variable should have employment protection-like effects, causing firms to

---

<sup>5</sup> Our index is constructed based on the OECD (1999) index for individual dismissal of workers with regular contracts, applying OECD weights. It includes scores for procedural inconveniences (procedures and delay to start notice) notice and severance pay for no-fault individual dismissal and difficulty of dismissal (definition of unfair dismissal, trial period, compensation and reinstatement). It is then combined with an index of the strictness of regulation of temporary employment, again based on OECD (1999), and smoothed over time.

become more choosy, and so increasing education requirements, and reducing the standard deviation of starting age.

Similarly, strong unions are likely to play a role in promoting and enforcing employment protection and other labor regulation, as well as in pushing up wages generally, all of which will tilt labor demand in favor of skilled workers. Again, this effect should be seen in a decrease in the starting age standard deviation, and an increase in the education average. As noted above, union density at the plant level is not available over time, so we make do with national-level figures.

We also include the tax wedge for the country (total taxes divided by GDP), on the argument that when taxes increase labor cost, this may reduce the relative demand for unskilled workers. This argument requires wage inflexibility; otherwise tax increases will be shifted back toward the worker, with little effect on labor demand.

A further variable is unemployment. For example, it might be that in bad times, the relative demand for unskilled workers decreases, since firms tend to hoard skilled labor then (Reder, 1955; Devereux, 2000). Conversely, in good times, skilled labour takes time to train, so firms must take unskilled workers, and the relative demand for unskilled workers increases. However, for our firms there might also be counteracting cyclical shifts in unskilled labour supply<sup>6</sup>. Our firms are mainly in non-durable manufacturing which has less cyclical employment variation than durable (McLaughlin and Bils, 2001). Thus, in slack times many unskilled workers will be searching for a job in non-durables (they are laid off from durables), causing a relative fall in unskilled wages and maintaining unskilled recruitment in non-durables. To allow for such effects, we incorporate as controls both the plant's employment deviations from trend, and also the national unemployment rate.

### 3. The Data

The sample includes data from four major manufacturing multinationals, most with plants in the US, the UK, and a country in continental Europe. The companies were chosen because they had subsidiaries in both regulated and unregulated countries, were large enough to regularly hire workers, and had 15-20 years past personnel record data. The industries involved are ice-cream manufacturing (Italy, the UK, and Missouri for the US), distilling (Italy, the UK, and California for the US), food processing (Netherlands, the UK, and Maryland for the US) producing mainly margarine, and pharmaceuticals (Belgium and the UK) producing penicillin products (for details, see Daniel and Siebert, 2003).

Basic employment and labor costs data for the resulting sample are given in Table 2. As can be seen from the table, labor costs per production worker tend to be lowest in the UK plants. The pharmaceuticals pair shows the biggest difference; with labor costs in the Belgian plant being more than twice UK costs, due to higher Belgian labor taxes and extended collective agreements. Nevertheless, unit labor costs are similar in the two plants (\$165 to \$175 per \$000 sales) indicating that the Belgian plant is securing a level of labor productivity which is twice as high as that of its UK counterpart. We would expect such differences to feed through to the hiring process, with the Belgian plant concentrating more on prime-age, educated workers than its UK counterpart.

---

<sup>6</sup> For an early discussion of how supply shifts may affect relative wages and employment, see Perlman (1958).

Table 2 also shows unit labor costs appear to differ quite widely for the distillers' plants (from \$0.049 to \$0.099 per liter), and food processing plants (\$49 to \$74 per ton), which may undermine the competitive assumption (the more expensive plants should have been eliminated over time). However, it is difficult to calculate the labor productivity factor underlying unit labor costs. Moreover, the exchange rates used are problematic. Therefore, we believe that these differences should not be taken as strong evidence against the competitive assumption.

Information on mean values of the labor demand variables is given next, in Table 3. The first row shows that the data period is about 20 years, 1975-95, in most cases, though the ice-cream plant in Italy yielded only 12 years of observations, 1985-97. Hence, we have achieved a serviceable time series. Admittedly, the following rows show that the average number of hires per year is quite low in some plants, so the means and standard deviations will be unreliable<sup>7</sup>. To help circumvent this problem, as noted above, we use the underlying number of observations as arithmetic weights.

As for the starting age variable, the mean values are in the late twenties for most plants. Thus, school-leavers are generally not hired<sup>8</sup>. The high starting age values show the emphasis on previous experience amongst this group of large plants. Nevertheless, the standard deviation of starting age is smaller in plants in Italy, the Netherlands and Belgium, where employment protection legislation is stricter, as expected.

The education variable rows show the US plants to have highest average education, at around 12 years, almost 2 years higher than the Italian plants. At first glance, this pattern runs counter to our hypothesis that strict employment protection should result in more emphasis on education. However, country laws on the school-leaving age, which is low in Italy, could affect the average – as well as differences in country wealth. These factors should be picked up in the fixed effect (in addition, there have been changes in school-leaving laws, for which we include a school-leaving age dummy). Table 3 also shows the standard deviation of education of new hires, which varies from 1 to 2.5 years. There is no particular pattern in the cross section, comparing countries, nor do we expect any. We will now explore these relationships more systematically.

#### 4. Results

The main results: The main results are given in Table 4. For each dependent variable, we report results using the Blanchard-Wolfers index as well as our index. Since it is necessary to pick up plant-specific unobservables, as noted above, we include fixed effects in all specifications. F-tests show that we can assume the same coefficients for all plants, apart from the fixed effects. Although we experimented with various groupings based on plant ownership, these were not significant.

Estimation of the standard deviation equations is by ordinary least squares using underlying observations as arithmetic weights. However, because we expect starting age and

---

<sup>7</sup> For consistency over time, we concentrate on permanent males, defining “permanent” to include workers whether hired on a temporary basis or not, who became subsequently employed on an open-ended basis within a year. Where such hires fell below 2 in any year, we recorded a missing observation.

<sup>8</sup> However, an exception is the Italian distilling plant, which has starting age averaging only 23.7. Special factors seem to be operative in this plant, which recruits extensively among relatives of current employees. Such extra knowledge of applicants could allow age and education criteria to be lowered. Again, we rely on the fixed effects term in (9) to control for these special factors.

education to be determined jointly, the average age equation and the average education equation are estimated as simultaneous equations by three stage least squares, again including underlying observations as arithmetic weights.<sup>9</sup> In fact, as shown by the Durbin-Wu-Hausman test, average age is endogenous in the education equation (column 5) while average education is exogenous in the age equation (column 1) using the Blanchard-Wolfers index. It thus appears that we have a recursive system, with the personnel office making a decision first on an applicant's education, which is then traded off against starting age.

On the other hand, using our own index (columns 2 and 6), both education and age appear to be exogenous, which is puzzling since we expect simultaneity. However, at least this result means that we can use ordinary least squares, which provides a cross-check on the results using three stage least squares. (As a further cross-check, we also give in Appendix 2 reduced form equations for average starting age and education. ) The important point, as we will see, is that average education responds significantly positively to employment protection, whatever the specification.

Findings for employment protection are given in the top two rows. For the average starting age variable using the Blanchard-Wolfers index (column 1), the coefficient on employment protection, -1.60, is negative, but insignificant. If we use our own index (column 2), the coefficient on employment protection is also negative and insignificant, -0.50. These findings are in accordance with our model, which does not predict a strong link between employment protection and recruits' average age. At the same time, we see that education is strongly substitutable for starting age, which is plausible. This result is most marked using the Blanchard-Wolfers index: a one -year increase in recruits' education is associated with a 3.25-year decrease in starting age. Personnel offices evidently trade off education against starting age.

Turning to the standard deviation of starting age, we see the predicted contrast. Employment protection legislation significantly reduces the standard deviation of starting age in both specifications. This reduction is most marked using the Blanchard-Wolfers index (column 3), with a coefficient of -9.12. This reaction is in line with our model's predictions. The elasticity, taken at the means, is  $-0.99$  ( $= -9.12 \times 1.0/9.2$ ). Thus, moving Italy's employment protection level from 4 down to the average of 1, a change of  $-120\%$  ( $= (1-4)/\frac{1}{2}(1+4)$ ), would imply an increase of almost 120% in the standard deviation of starting age. Such a change would widen Italy's age standard deviation to about 11 years – approximately UK levels (Table 3). Using our own index (column 4), employment protection still significantly reduces the standard deviation of starting age, though to a lesser extent. Here the elasticity is  $-0.53$  ( $= -3.73 \times 1.3/9.2$ ), which implies moving Italy's employment protection level down to the average, would widen Italy's age standard deviation to about 8 years.

Turning next to average education, there is the predicted opposite pattern in both specifications. Using the Blanchard-Wolfers index (column 5), average education responds significantly to the employment protection index, with a coefficient of 2.35. The elasticity is 0.21 ( $= 2.35 \times 1.0/11.4$ ). This elasticity is smaller than that for the standard deviation of starting age, but this is appropriate since education levels cannot vary much. Thus, moving Italy's employment protection level once again by  $-120\%$  would imply a reduction of 25% in

---

<sup>9</sup> The instrument we used for education was the school-leaving age variable, which can reasonably be excluded from the age equation. The instrument we used for starting age was the average age of the company's worker stock which, for its part, can reasonably be excluded from the education equation.

the Italian firms' education levels, which is quite enough (given Italy's already low education levels). Using our index (column 6), the elasticity is, 0.17 ( $=1.47 \times 1.3 / 11.4$ ), implying a reduction of about 20% in the Italian firms' education level if Italy's employment protection level moves down to the average. The positive link between employment protection and average education remains in the reduced form specification (Appendix 2).

Finally, the last two columns show that the standard deviation of education does not respond significantly to employment protection using either measure. This result is also consistent with our model, which makes no predictions for the standard deviation of education.

The pattern of results for the remaining variables also gives confidence in the model, though the results are somewhat stronger using the Blanchard-Wolfers index. Thus, when using this index, the time trend variable (column 3) shows that the standard deviation of starting age has been trending downward, at  $-0.34$  years per year. At the same time, the average education of recruits (column 5) has been trending significantly upward, at 0.08 years per year. (The education trend is not simply a consequence of the school-leaving age increase that occurred in some countries during the period, since we have the school-leaving age control, which is significant.) These results are sensible. They indicate that management has been becoming choosier over the years, raising education, and more tightly defining starting age, which could reflect global competition and/or skill-using technical progress raising skill requirements.

The main other significant controls are for business conditions, that is, the unemployment and deviations from employment trend variables. Both variables point to a rise in recruiting standards when business is good. Thus, we see that lower unemployment is linked to an increase in average education. Similarly, a positive employment deviation from trend is linked to a reduction in the standard deviation of starting age. The simple argument, as we noted above, is for good business conditions (low unemployment) to favor lower recruitment standards, as firms run out of hoarded skilled labour. However, as we also noted above, supply shifts could explain our contrary findings, since few unskilled workers may be looking for jobs in non-durable manufacturing when unemployment is low, given the likely strong expansion in (better-paying) durable manufacturing at such times. Scarcity of unskilled workers could thus explain the apparent rise in recruiting standards in our sector when times are good.

The union density and the tax wedge variables produce mixed results. We argued above that both should have employment protection-like effects. Hence, we would expect negative coefficients on these variables in the standard deviation of starting age equation, and positive in the average education equation. Using the Blanchard-Wolfers index, union density significantly reduces the standard deviation of starting age, as expected, but it is insignificant in the average education equation. Using our index, the coefficient on union density is insignificant in both equations. However, our union density data are at the country level, not the plant level, since a time series of union density at the plant level is not available. Most of the plants had closed shops even in the 1990s (over 90% union density – see Table 2), so union density is likely to have been pretty constant over time, making our country series inappropriate. As for the tax wedge, this variable is significantly positively linked with average education as expected. However, it is insignificant in the age standard deviation equation, in both specifications. The effects of union density and the tax wedge are not clear cut, therefore, though some results go in the expected direction.

Finally, the manufacturing pay variable is trying to be significant in the expected directions. In other words, there are signs that personnel offices become more choosy when manufacturing pay levels are high, so recruits need to be more educated, and at the same time the standard deviation of starting age tends to fall.

Sensitivity tests: First, we exclude the three US plants, and look only at plants in the European subset of countries using both indices. This test aims to show whether these employment protection results are robust to a big change of sample. In addition, the test circumvents the possible problems of the Blanchard-Wolfers US employment protection index, which omits judge-made employment protection (see above).

Summary results are given in Table 5, Panel A<sup>10</sup>. We report the coefficients of both the employment protection indices and the time trend, the time trend being interesting because it should show a common country tendency towards a shrinking market for unskilled labor. Taking first Blanchard-Wolfers employment protection measure in the upper panel, the first row repeats Table 4's results for reference. The second row gives the results for the Europe-only sample. We see the same pattern: higher employment protection reduces the standard deviation of starting age, and increases average education, leaving the other two dependent variables unaffected. Hence our results are not much affected by the change in sample. Turning to our own measure, the pattern does not hold for the standard deviation of starting age equation for the Europe only sample. Hence, changing the sample size gives more confidence in the Blanchard-Wolfers measure.

Now turn to the time coefficients in the second row. The main feature here is that both employment protection indices produce a significant negative time trend for the standard deviation of starting age, and a significant positive time trend for average education for the overall sample. These findings indicate that management has been becoming choosier over the years, which could reflect global competition raising skill requirements, as noted above. However, using either index, there is no significant time trend in the Europe-only sample. Increasingly stringent hiring standards appear only to affect the US plants over this time period, according to this specification. This result could be due to the fact that US plants have had more room to raise their standards as global competition bites – standards in continental European plants already being quite high.

Our second test groups observations into 5-year averages, as shown in Panel B. The advantage of such grouping is that the number of observations underlying the dependent variables (means or standard deviations) is increased, so weighting is unnecessary. Also, reducing the number of datapoints per plant to 3 or 4 over time might more truly reflect the amount of information we have on employment protection, given that the indexes are static for long periods at a time. As can be seen, there is still a negative link between employment protection and the standard deviation of starting age, though the elasticity is reduced to about  $-0.2$ . Also, there is still a positive link between employment protection and education, this time with an increased elasticity of 0.64 to 0.85. However, in this formulation there is now a positive link between employment protection and the standard deviation of education, which is not expected by our theory. Nevertheless, the main results survive.

Our final test probes the employment protection indices. Specifically, we test for the strength of the association between both measures of employment protection and average

---

<sup>10</sup> Full details are available from the authors on request.

worker tenure in the plants. Our argument here is simply that high tenure in a plant should indicate high employment protection in that plant. The tenure variable is constructed using the average tenure of the workforce in a given year. Admittedly, average plant tenure changes only slowly in response to changes in the legal environment. Nevertheless, we think the exercise can still provide a check on the indices.

The results are given in Table 6, which shows a strong association between employment protection and plant tenure using the Blanchard-Wolfers index. The association is somewhat weaker using our alternative index. The coefficient on employment protection using the Blanchard-Wolfers index is 9.64 and highly significant, implying an elasticity, taken at the means, of 1.09 ( $=9.64 \times 1.3/11.5$ ). While labor turnover is not the focus of our inquiry, both equations behave quite well, with the expected negative link between plant employment deviations and tenure (positive deviations mean more hiring, and should lead to a lowering of average tenure), and positive time trend. However, the equation using our measure throws up a negative relation between union density and tenure, which is hard to explain. These results therefore give particular confidence in the Blanchard-Wolfers employment protection index.

## 5. Conclusions

This paper develops and tests a model in which employment protection costs can influence the type of labor characteristics demanded by employers. The model postulates that workers with little education, or in the tails of the age distribution, have more chance of failure (mismatch), and thus of imposing hiring and firing costs on the firm. Consequently, such workers are less likely to be recruited when strict employment protection raises hiring and firing costs. In particular, the model predicts that recruits' *average* education should increase and the *standard deviation* of starting age should decrease when employment protection becomes stricter. As Table 4 shows, our model's predictions are borne out using two alternative measures of employment protection, with the results being somewhat stronger using the Blanchard-Wolfers index. Strict employment protection indeed reduces the variability in starting age, and raises education requirements, independent of the employment protection measure used. Hence, there are strong indications that employment protection affects the steady-state distribution of recruits' characteristics – raising education requirements, and reducing starting age dispersion.

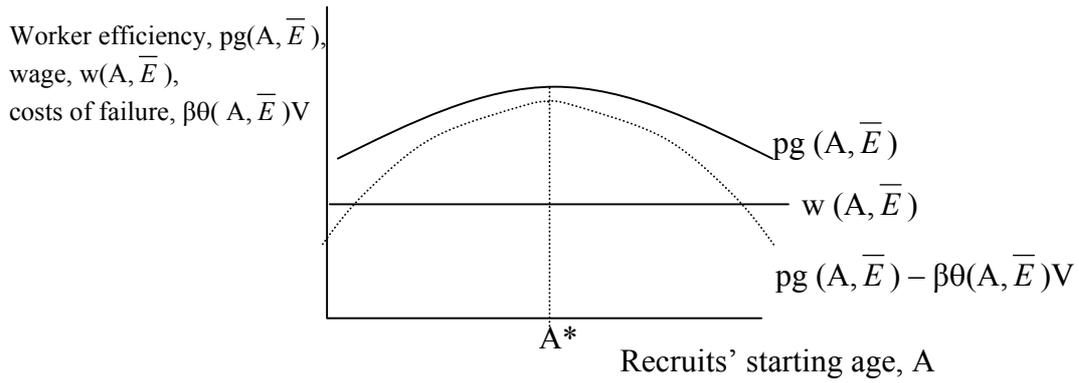

The adverse distributional impact of employment protection legislation, implied by our results, has become increasingly apparent from recent OECD country studies which disaggregate by age, as noted in the introduction. We offer a further disaggregation by education, and a different firm-based methodology to arrive at the same conclusion. Our study shows that employment protection is generally bought at a cost to the inexperienced, the old, and the uneducated – the have-nots.

Caveats and directions for further research must be noted. In the first place, our results depend upon the measurement of employment protection. We have shown that the employment protection indicators we use generally behave sensibly when explaining patterns of workforce tenure in our sample. That is, average worker tenure increases strongly in plants/time periods with strict employment protection (Table 6). The results also survive when we radically alter the sample by dropping all the US observations using the Blanchard-Wolfers index (but only partly using our index – see Table 5). Further work is necessary on measurement of employment protection. In particular, our post-1975 period has little variation in employment protection, since the system is essentially mature. A more powerful

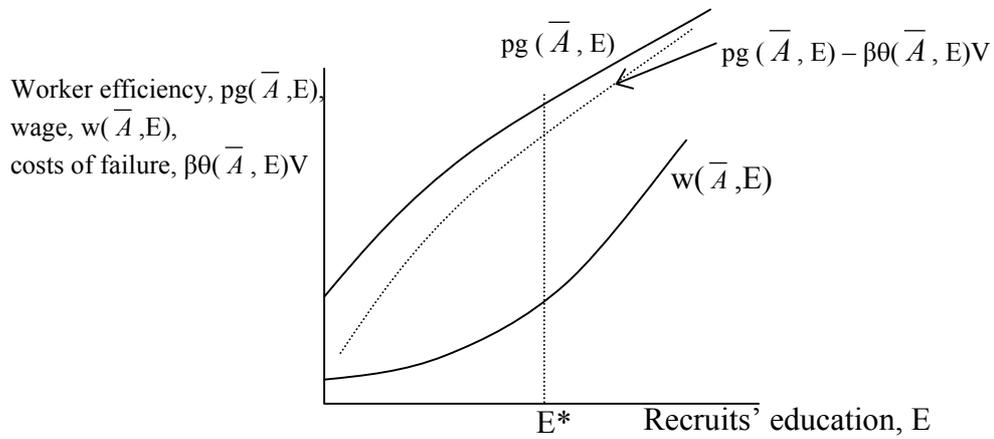

analysis would be possible with data extending back into the 1960s, when the continental European countries were setting up their employment protection measures – though it would be an unusual firm which kept personnel record data extending back so far.

A second point arises about the generalizability of our results. Our data are reasonably consistent across countries because they come from subsidiaries of four multinationals, which impose a reporting uniformity. Also, all the subsidiaries are in a similar industrial sector, nondurables manufacturing, and we consider the hiring only of males into contracts which are open-ended (or become so within a year). These restrictions reduce extraneous noise. However, small firms, the service sector (including government), and the market for temporary workers are all excluded from consideration. There is work to be done to fill this gap. In particular, it is important to understand how the increasing use of temporary contracts allows some firms to contract around employment protection and experiment with unskilled groups. The large company, industrial sector, to which our results apply, is only a small part of the whole.

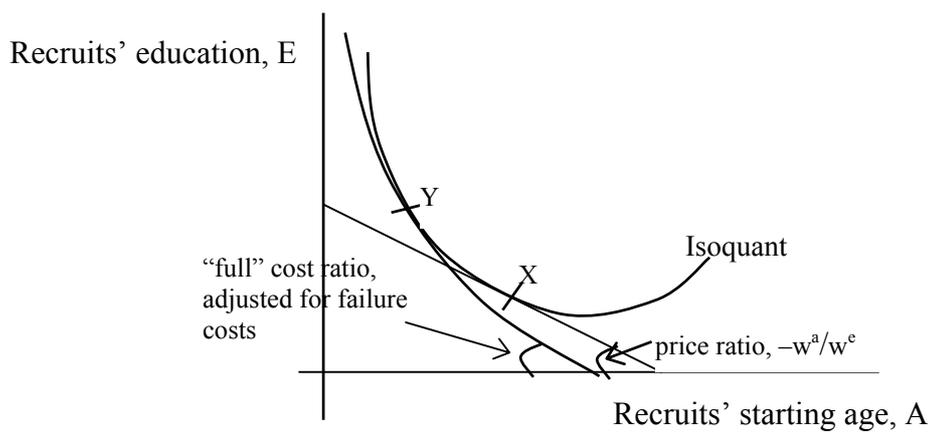

Nevertheless, our results show how employment protection legislation can influence recruiting decisions at the level of the company. Company time series studies bring their own difficulties in terms of missing information. However, the company is where the employment decisions are made. Rather than relying on country aggregates such as employment-population or unemployment rates, which are the subject of many factors, we are therefore able to provide specific tests of important employment decisions.

## Appendix 1: Comparative statics results

Differentiating equations (6) and (7) totally we derive:

$$(pg_{AA} - w_{AA} - \beta V \theta_{AA})dA + (pg_{AE} - w_{AE} - \beta V \theta_{AE})dE = \beta \theta_A dV$$

$$(pg_{EA} - w_{EA} - \beta V \theta_{EA})dA + (pg_{EE} - w_{EE} - \beta V \theta_{EE})dE = \beta \theta_E dV$$

Solving for  $dA/dV$  using Cramer's rule gives:

$$\frac{dA}{dV} = \frac{\begin{vmatrix} \beta \theta_A & pg_{AE} - w_{AE} - \beta V \theta_{AE} \\ \beta \theta_E & pg_{EE} - w_{EE} - \beta V \theta_{EE} \end{vmatrix}}{\begin{vmatrix} pg_{AA} - w_{AA} - \beta V \theta_{AA} & pg_{AE} - w_{AE} - \beta V \theta_{AE} \\ pg_{EA} - w_{EA} - \beta V \theta_{EA} & pg_{EE} - w_{EE} - \beta V \theta_{EE} \end{vmatrix}}$$

Second order conditions require the determinant of the denominator,  $\Delta$ , to be positive for a maximum. On the education side, we require  $w_E > 0$  and  $w_{EE} > 0$  (wages increase at an increasing rate as shown in Figure 2). We have no priors about  $\theta_{EE}$ , and so assume  $\theta_{EE} = 0$ . We also assume  $g_E > 0$  and  $g_{EE} < 0$  (diminishing returns to education). On the starting age side we assume  $g_A > 0$ ,  $g_{AA} < 0$  (an inverted U for worker efficiency by age as shown in Figure 1),  $\theta_A > \text{or} < 0$ , and  $\theta_{AA} > 0$  (failure probability is U-shaped with age, though the reaction could be near-zero for workers in the prime age group). We have no priors regarding  $w_A$  and  $w_{AA}$ , and so assume  $w_A = w_{AA} = 0$ . Finally, we assume all cross-products zero, except for  $g_{AE} > 0$ .

We then see that  $dA/dV$  is  $>$  or  $<$  0 since:

$$\frac{dA}{dV} = \frac{\begin{vmatrix} \beta \theta_A & pg_{AE} \\ \beta \theta_E & pg_{EE} - w_{EE} \end{vmatrix}}{\begin{vmatrix} pg_{AA} - \beta V \theta_{AA} & pg_{AE} \\ pg_{EA} & pg_{EE} - w_{EE} \end{vmatrix}}$$

$= ((pg_{EE} - w_{EE}) \beta \theta_A - \beta \theta_E pg_{AE})/\Delta$  which is  $>$  or  $<$  0 since the first term is positive or negative, depending on  $\theta_A$ , and the second is negative.

However,  $dE/dV$  is likely to be  $>$  0, since by a similar procedure we find:

$$\frac{dE}{dV} = \frac{\begin{vmatrix} pg_{AA} - \beta V \theta_{AA} & \beta \theta_A \\ pg_{EA} & \beta \theta_E \end{vmatrix}}{\begin{vmatrix} pg_{AA} - \beta V \theta_{AA} & pg_{AE} \\ pg_{EA} & pg_{EE} - w_{EE} \end{vmatrix}}$$

$= ((pg_{AA} - \beta V \theta_{AA}) \beta \theta_E - \beta \theta_A pg_{AE})/\Delta$ . Here the second term depends on  $\theta_A$ , and so again can be positive or negative. However, the first term is positive, and grows larger with  $V$ . Where  $V$  is sizeable, therefore, we can be confident that  $dE/dV > 0$ .

### **Abstract**

While popular sentiment suggests that strict employment protection legislation will tend to weaken the attractiveness of a country as a location for FDI, theoretical predictions on this issue are mixed. In this study, we report empirical evidence on this issue, using panel data for a sample of OECD countries. Overall, our findings support the view that increases in the strictness of regulations governing employment contracts may have a deterrent effect on FDI. However, we find evidence for a non-linear effect, such that very high levels of employment protection may actually help to make an economy a more attractive location for FDI.

JEL codes: F21, J58

## 1. Introduction

What are the factors that help to make a country a more – or less – attractive location for foreign direct investment (FDI)? The substantial increase in global flows of FDI that has occurred in recent years has prompted a renewed interest in this question both from academics and policy-makers. In response, a vast literature, featuring both theoretical and empirical contributions, has emerged; the main findings of which, are surveyed admirably in a recent book by Moosa (2002).

A view that seems to have gained popularity amongst policy-makers - in Anglo-Saxon economies, at least - is that greater labour market flexibility helps to make a country a more attractive location for FDI.<sup>1</sup> A corollary of this is that a strict regime of employment protection legislation, which is often held to inhibit labour market flexibility, will tend to diminish a country's attractiveness as a location for FDI. Recent theoretical analysis has lent some support to this view. In two recent theoretical contributions, Haaland and Wooton (2001, 2002) observe that in an environment of uncertainty multinational enterprises will want to take account of future exit costs when deciding on the location of a new investment. Employment protection legislation – e.g. in the form of statutory redundancy payments – will tend to add to the scale of future exit costs. Countries with relatively strict employment protection legislation will therefore tend to be less attractive locations for FDI, other things equal, than countries with relatively weak employment protection regimes.

Theoretical analysis does not present unambiguous predictions concerning the effect of employment protection legislation, however. Dewit et al (2003) show that if firms act strategically there may be circumstances in which it would be advantageous to locate in a country with a strict employment protection regime. The explanation is

that strict employment protection raises the costs of adjustment for firms that change the scale of their production. Therefore, if a firm wishes to commit to maintaining a particular output level it may be in its interests to locate in a country with a strict employment protection regime.

To date, there appears to have been only one empirical study that has attempted to address the issue of the influence of employment protection legislation on FDI. The study by Cooke (1997) presents a cross-section econometric analysis of the determinants of the location decisions by U.S. multinational enterprises in a number of industries. Based on a classification of the strictness of the employment protection regime in different countries due to Emerson (1988), Cooke finds that, other things equal, investment by U.S. multinationals is significantly lower in the six countries (France, Greece, Italy, the Netherlands, Portugal, and Spain) that have the tightest restrictions on the ability of firms to lay off redundant workers.

Cooke's study is limited in that he focuses on the investment decisions of multinational companies of a single country (albeit that U.S. firms are important contributors to global flows of FDI), using data for a single point in time (the early 1990s), and in that the dummy variable he uses represents a relatively crude measure of the effects of employment protection. In the light of these limitations, there is scope for a more extensive examination of the relationship between the strictness of employment protection legislation and the direction of international flows of FDI.

The present paper aims to test the hypothesis that strict employment protection legislation helps to deter FDI. The study therefore contributes to the growing literature that examines the effect of employment protection legislation (EPL) on economic performance. Most of the existing literature has focused on the labour

---

<sup>1</sup> This view has been expressed by the United Kingdom government, for example. See HM

market effects of EPL. In particular, studies have examined the impact of EPL on the rate and structure of unemployment (see for example: Bertola, 1990; Gregg and Manning, 1997; and Nickell, 1997), the pattern of worker and job flows (Schettkat, 1997; Boeri, 1999), and the structure of employment (OECD, 1999; Bertola et al, 2002; Robson, 2003). On the whole, the evidence from these studies is rather mixed. While stricter EPL appears to influence both the duration and demographic composition of employment and unemployment, there is little evidence to suggest that it has a significant impact on either the average rate of unemployment or the employment-population ratio. In spite of this rather mixed evidence on the effects of EPL, the view appears to have taken hold in policy-making circles that strict employment protection legislation is detrimental to economic performance, and is a significant factor in explaining the recent sluggish performance of many European economies relative to that of the United States (see for example OECD, 1994).

In order to examine the effects of employment protection legislation on FDI we make use of an indicator of the strictness of EPL constructed by Blanchard and Wolfers (2000). This indicator, which is developed from previous work carried out by the OECD (OECD, 1999) and Lazear (1990), covers a number of OECD countries and is available for a sequence of five -year periods from 1960-4 through to the mid-1990s. We make use of a subset of the data, corresponding to the figures that we have available for FDI. We estimate panel data regressions of aggregate inflows of FDI on employment protection and a set of additional explanatory variables that have been found in previous studies to have a significant effect on FDI flows.

Overall, our results are supportive of the notion that strict employment protection legislation may help to reduce the attractiveness of a country as a location

---

Government (1996).

for FDI. In particular, our results suggest that FDI is particularly attracted to countries with very weak EPL. At higher levels of EPL, however, the effect of further restrictions on hiring and firing becomes relatively weak and may indeed become positive.

The outline of the remainder of the paper is as follows. In section 2, we discuss the data and the specification of our basic empirical model. Section 3 reports the results, while section 4 provides concluding comments.

## 2. Data and Empirical Specification

The measure of the strictness of employment protection legislation we use for this study is the indicator constructed by Blanchard and Wolfers (2000) for their investigation of the role of shocks and institutions in the determination of OECD unemployment. The Blanchard and Wolfers measure is a summary indicator of the overall strictness of EPL that builds on previous work carried out by the OECD (OECD, 1999) and Lazear (1990). The indicator is scaled to lie between a minimum value of 0 (corresponding to very weak employment protection) and a maximum of 6 (corresponding to very strict protection). The data is available for a number of OECD countries, in the form of five-year average values over the period from 1960 through to the mid-1990s, though in this study we use data only from 1965-9 onwards, corresponding to the availability of data on FDI flows.<sup>2</sup>

The Blanchard-Wolfers measure embraces a wide range of restrictions on the use of labour, including regulations governing the use of fixed term contracts and the activities of temporary work agencies. In contrast, the model put forward by Haaland and Wooton (2001, 2002) suggests that the influence of employment protection on FDI is likely to come through its effect on the scale of exit costs. These are most likely to be related to regulations relating to the cost of dismissals, in particular collective dismissals - for example, regulations governing the size of severance payments and periods of advanced notice of dismissal. These are the focus of the measures constructed by Lazear (1990) (which are used by Blanchard and Wolfers in the construction of their indicator). However, the Lazear measures are only available up to 1984, which limits their usefulness for an analysis of the determinants of FDI. Of the several measures of the strictness of EPL that have appeared in the literature,

the Blanchard-Wolfers indicator offers the most extensive coverage and despite its limitations is therefore the one that we use in our analysis.<sup>3</sup>

Table 1 shows selected values of the Blanchard-Wolfers indicator of the strictness of EPL for the countries in our data sample. The data indicate that the overall strictness of EPL tends to be highest in the southern European countries – Greece, Italy and Spain – and weakest in the USA, Canada and the United Kingdom. A number of countries – Belgium, Denmark and Sweden among them – appear to have introduced measures to relax the strictness of EPL in their economies during the 1990s. The main exception to this trend was in France, where the 1990s saw further tightening of the employment protection regime through the imposition of tighter restrictions on the maximum cumulative duration of fixed term contracts and tighter limits on the scope of the activities of temporary work agencies.<sup>4</sup>

We have two sets of data on FDI; one measured at the aggregate level, the other disaggregated by sector. At the aggregate level, we use the data on inflows of FDI published in the IMF *International Financial Statistics Yearbook*. The data, which are expressed in national currencies, are converted into U.S. dollars using current exchange rates and deflated by the U.S. GDP deflator. The sectoral data is taken from the OECD's *International Direct Investment Statistics Yearbook* (OECD, 1999b). The sectors for which data is available are listed in the Data Appendix.

---

<sup>2</sup> Note that the final observation for each country included in the data series is a three-year average for the period 1995-7. See the Appendix to Blanchard and Wolfers (2000) for details of the construction of the data series. The Appendix is available at <http://econ-www.mit.edu/faculty/blanchar/papers.htm> .

<sup>3</sup> Other studies that have attempted to construct comparative measures of the strictness of EPL across different countries include Emerson (1988), Bertola (1990), Grubb and Wells (1993) and OECD (1999a).

<sup>4</sup> Further discussion of recent developments in employment protection legislation in OECD countries is contained in OECD (1999a).

Figure 1 provides a cross-plot of observations on the natural log of real aggregate FDI flows and the Blanchard-Wolfers indicator of the strictness of EPL.<sup>5</sup> The cross-plot provides preliminary evidence in support of a negative relationship between the two series, although the relationship is subject to significant dispersion. Closer inspection suggests the possibility that there may be non-linearities in the relationship between EPL and FDI. In particular, the relationship appears to exhibit something of an s-shaped pattern, such that there appears to be a relatively strong effect of EPL on FDI for countries with either very weak or very strong employment protection but a relatively weak effect for countries in between in these extremes.<sup>6</sup> We investigate this issue more fully in our more formal empirical analysis below.

In order to test the hypothesis of a negative relationship between the strictness of employment protection legislation and inflows of FDI more thoroughly, we need to control for the presence of other potential influences on FDI. We therefore include as additional explanatory variables in our regressions a list of variables that have been found in other studies to have a significant effect on the attractiveness of a country as a location for FDI. These are: the level and growth of real GDP, the productivity adjusted real wage, openness to trade, the real exchange rate (more specifically, we include a measure of real exchange rate depreciation), corporate taxes as a percentage of GDP, and the host country unemployment rate. The level of real GDP is included as a measure of the market size of the host country and is expected to have a positive effect on inflows of FDI (see Moore, 1993; Bajo-Rubio and Sosvilla-Rivero, 1994; Wang and Swain, 1995; Billington, 1999; and Cleeve and Ndhlovu, 2001, amongst others, for evidence in support of this), as is the rate of growth of real GDP. The

---

<sup>5</sup> Note that this cross-plot includes observations for a number of countries – Iceland, Korea, Luxembourg, Mexico, Portugal and Turkey – that are excluded from the sample used in our regression analysis as we do not have complete data for these countries on the full set of explanatory variables used in our analysis.

evidence on the effects of the other variables is mixed, with some studies finding positive effects; others negative effects; and others still, no significant effect.<sup>7</sup>

The variables listed above, plus a time trend to capture the general increase in FDI flows over time, form the set of control variables we use in our regression analysis to investigate the issue of whether strict employment protection legislation serves to deter FDI.

---

<sup>6</sup> We are grateful to Jonathan Wildman for this observation.

<sup>7</sup> Recent studies on the effects of real wage costs include Moore (1993), Pain (1993), Bajo-Rubio and Sosvilla-Rivero (1994), Wang and Swain (1995), Love and Lage-Hidalgo (2000), Billington (1999) and Wheeler and Mody (1992). Evidence on the effects of trade openness may be found in Kravis and Lipsey (1982), Edwards (1990) and Yang et al (2000). For evidence on exchange rate effects see Caves (1988), Froot and Stein (1991), Blonigen (1997), Görg and Wakelin (2001) and Yang et al (2000). Grubert and Mutti (1991), Wheeler and Mody (1992), Hines and Rice (1994), Swenson (1994), Jackson and Markowski (1995), Loree and Guisinger (1995), Mudambi (1995), Porcano and Price (1996), Cassou (1997), Kemsley (1998), Billington (1999) are among a host of studies that have examined the effect of corporate tax rates on multinational enterprise location decisions. Finally, the effects of the host country unemployment rate in the have been studied by Billington (1999) and Cassou (1997).

### 3. Empirical Analysis

Table 2 reports the results of our initial panel data regression analysis. Three sets of results are shown. Columns (1) and (2) show the results from regressions using data on aggregate FDI flows. For these regressions, we have an unbalanced panel of 108 observations as data on FDI and/or one or more explanatory variables are missing for some time periods. The countries for which data are used are listed in the Data Appendix.

The estimates in column (1) are obtained using Feasible GLS estimation, with allowance for heteroskedasticity and autocorrelation in the equation disturbances<sup>8</sup>. They show a strong negative effect of EPL on inflows of foreign direct investment, with significant effects also for the level and growth of real GDP, real exchange rate depreciation, and the host country unemployment rate. Insignificant effects are found for the corporate tax burden, openness and the productivity-adjusted real wage.

The positive sign for the coefficient of the log of real GDP supports the common finding that market size is an important influence on the attractiveness of a country as a location for FDI, while the positive coefficient for real GDP growth suggests that FDI is attracted to growing markets. The positive sign for the coefficient on the host country unemployment rate suggests that the availability of labour may be an important factor in the location decisions of multinational enterprises. Alternatively, it may be the case that the governments of countries with relatively high rates of unemployment are willing to offer higher subsidies in order to attract multinational enterprise investment. Finally, the negative coefficient for the depreciation of the real exchange rate is consistent with the notion that FDI may be a substitute for trade. In addition, it is possible that the currency depreciation variable

---

<sup>8</sup> All results are obtained using version 7.0 of Stata.

may be picking up the effects of exchange rate volatility on the incentives for FDI (Campa, 1993).

The second column of Table 2 shows the results from a random effects specification that allows for the presence of unobserved country-specific effects on FDI inflows. These unobserved effects include the effects of persistent characteristics, such as geographical proximity to markets, language spoken, etc., that may make countries more or less attractive locations for FDI. The results show that although rather weaker, the negative effect of EPL remains statistically significant at the 10% level (5% on a one-tailed test).<sup>9</sup>

In column (3), we report the results of estimating our equation using sectorally disaggregated data on FDI flows<sup>10</sup>. The regression equation includes sectoral dummies and the coefficient standard errors are adjusted to allow for the ‘clustering’ of observations due to the fact that the explanatory variables are measured at the aggregate level (Moulton, 1986). The magnitude of the coefficient for EPL is much smaller than in the equations estimated using aggregate data, but once again it is statistically well determined.<sup>11</sup> Overall then, the evidence we have presented so far provides support for the notion that a strict regime of employment protection legislation may serve to deter FDI.

#### *Are There Non-linearities in the Relationship Between EPL and FDI?*

In Section 2, we raised the possibility, based on an examination of the data in Figure 1, that there may be non-linearities in the relationship between EPL and FDI.

---

<sup>9</sup> We have also estimated fixed effects specifications. In these, the effect of employment protection legislation remains reasonably strong, particularly when the equation is estimated by Feasible GLS. However, the results of a Hausman specification test show that the results of the Random effects specification are narrowly preferred (the significance level for the test of the null hypothesis of random effects is 0.085). Moreover, it is worth noting that some of our explanatory variables exhibit relatively little time series variation. In such circumstances, fixed effects methods can lead to imprecise estimates and random effects estimation may therefore be preferable (Wooldridge, 2002).

To investigate this, we experimented with estimating a variety of non-linear functional forms, including quadratic, cubic and piecewise linear specifications. Of these, the quadratic specification appears to work best, both in terms of goodness of fit and in terms of providing a model with intuitively interpretable coefficients. The results are reported in Table 3.

The quadratic term in the employment protection index is insignificant in the random effects specification but strongly significant in the equation estimated by Feasible GLS and in the equation estimated using sectorally disaggregated data. The coefficient estimates suggest that starting from a position of very weak employment protection legislation there is a strong deterrent effect on inward FDI as the strictness of employment protection legislation is increased. However, this deterrent effect tails off quite rapidly and in fact seems to disappear at intermediate levels of employment protection, corresponding to a value of the employment protection index of just below three. Beyond this, the effect of stricter employment protection legislation appears, if anything, to be positive.

The apparent non-linearity in the relationship between employment protection legislation and inward FDI suggests that for multinational enterprises seeking mobile investment opportunities employment protection legislation may be perceived as imposing a potential fixed cost on their operations, which they are keen to avoid. FDI is therefore particularly attracted to countries with very weak employment protection legislation. This is supported by the results of an alternative specification in which we include a dummy variable for countries with values of the employment protection index below 1.5 (results available from the authors on request). Alternatively, the finding of a quadratic relationship could be consistent with the work of Dewit et al

---

<sup>10</sup> Details of the sectors included are given in the Data appendix.

(2003), who show that while in general increases in the strictness of employment protection legislation may be expected to have a deterrent effect on inward FDI, strategic motives may in some circumstances lead firms to locate in countries with relatively strict regimes of employment protection legislation.

---

<sup>11</sup> The coefficient for the log of real GDP is likewise reduced in magnitude.

## 4. Conclusions

In this study, we have set out to examine the hypothesis that a strict employment protection regime reduces the attractiveness of a country as a location for FDI. This view, which seems to have gained popularity with policy makers and other commentators, has received theoretical support in two recent papers by Haaland and Wooton (2001, 2002). Further work by Dewit et al (2003), however, shows that if firms act strategically there may be some circumstances in which firms may find it in their best interests to locate in countries with relatively strict employment protection.

In examining the relationship between the strictness of employment protection and FDI, we have made use of a summary indicator of the strictness of employment protection legislation in a number of OECD countries, constructed by Blanchard and Wolfers (2000). We have estimated panel data regressions using five-year average values of aggregate and sectorally disaggregated data for the period from the 1970s through to the mid-1990s. The results from this analysis are largely supportive of the hypothesis that a strict regime of employment protection serves to deter inward investment by multinational enterprises. They may therefore be seen as reinforcing and supplementing the earlier empirical findings of Cooke (1997).

The effect of employment protection legislation is found to be quantitatively as well as statistically significant. There is some variation in the estimated effect of EPL depending on the data used and the specification chosen. However, using the semi-log specification in Table 2, our most conservative estimate (from column (3)) suggests that other things equal a one unit decrease in the value of the indicator of the strictness of EPL (equivalent, for example, to the difference in the value of the indicator between Italy and the Netherlands in 1995-7) is associated with an increase

in the real value of inflows of FDI of six percent; comparable to the effect of a one percent increase in the log of real GDP.

These results may therefore be seen as lending support to the position of those governments and commentators who have advocated the merits of flexible labour markets as a means of attracting internationally mobile FDI. However, the evidence we have found for a quadratic relationship between employment protection and FDI suggests that matters may not be this straightforward. The latter suggests that while countries with relatively few restrictions on hiring and firing may gain benefits in terms of attracting inflows of FDI from a further relaxation of legislation in this area, countries with relatively strict regimes of employment protection may gain from a further tightening of regulations. Such a policy prescription runs counter to much previous thinking on this issue and while it may in principle be defended on theoretical grounds as well as being supported by the empirical evidence, we would not necessarily want to press this claim too strenuously. The quadratic specification on which it is based should perhaps be seen as an approximation to a more complex non-linear relationship. Where we are confident, however, is in stating the finding that the deterrent effect of stricter employment protection legislation on FDI becomes weaker as the severity of restrictions on hiring and firing is increased.

All in all, our results are consistent with the notion that strict employment protection legislation may - up to a point at least - reduce the attractiveness of a country to FDI. As such, they support the proposition that a relaxation of the strictness of employment protection regulations may be a potentially powerful policy instrument for governments seeking to make their economies more attractive locations for multinational enterprise investment. However, insofar as the result may be believed, the finding that a very strict employment protection regime may actually help to make

an economy a more attractive location for FDI may serve to allay fears that competition between governments keen to attract internationally mobile investment may lead them into a 'race to the bottom' in labour standards relating to employment protection.

**Table 1. Selected Values of the Blanchard-Wolfers Index of the Strictness of Employment Protection Legislation**

<i>Country</i>	<i>1965-9</i>	<i>1985-9</i>	<i>1995-7</i>
Australia	1	1	1
Belgium	2.21	3.1	2.2
Canada	0.6	0.6	0.6

**Figure 1. FDI Flows and the Strictness of Employment Protection Legislation**

## Data Appendix

The countries included in the data sample used for the panel data regressions are: Australia, Austria, Belgium, Canada, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Japan, the Netherlands, Norway, New Zealand, Spain, Sweden, Switzerland, the UK, and the USA. Figure 1 features in addition data from Iceland, Korea, Luxembourg, Mexico, Portugal, and Turkey. These countries are excluded from the data sample used for the panel estimations because data for corporate taxes and/or wages are missing.

### FDI Inflows

For the aggregate data analysis, figures for inflows of foreign direct investment in national currencies dollars are compiled from the *International Financial Statistics Yearbook* of the IMF. These are converted into U.S. dollars using current exchange rates and then deflated using the U.S. GDP deflator.

For the sectoral analysis, we have data for the following sectors: mining and quarrying; agriculture and fishing; food production; textiles and wood production; petroleum, chemicals, rubber and plastic; metallic and mechanical products; machinery, RTV, computers and communications; vehicles and transport equipment; construction; trade and repairs; hotels and restaurants; land, sea and air transport; and financial intermediation. The data are taken from the OECD's *International Direct Investment Statistics Yearbook*.

### Employment Protection

As stated in the text, we use the summary indicator of the strictness of employment protection legislation compiled by Blanchard and Wolfers (2000). Details of the methods used to construct values of the indicator may be found in the Appendix to Blanchard and Wolfers' paper, located at <http://econ-www.mit.edu/faculty/blanchar/papers.htm>

### Real GDP and Real GDP Growth

Nominal GDP figures in national currencies are obtained from the *International Financial Statistics Yearbook*. These are converted to U.S. dollars using current exchange rates. Real values are then obtained by dividing by the U.S. GDP price deflator. The growth series is calculated as the percentage change from the previous year's real GDP figure.

### Productivity-adjusted Real Wage

The figures are obtained from the data set used by Blanchard and Wolfers (2000). See the Appendix to their paper for details of the method used to calculate the figures.

### Unemployment Rate

Standardised unemployment rates are obtained from the Blanchard-Wolfers database.

### Real Depreciation

The percentage change in the real exchange rate from the previous year (a positive value means a depreciation). Real exchange rates are calculated by multiplying the nominal exchange rate by the ratio of the U.S. GDP deflator to the GDP deflator of

the home country. The source for all series is the *International Financial Statistics Yearbook*.

Openness

This is defined as the sum of exports plus imports as a percentage of GDP. The component series are obtained from the *International Financial Statistics Yearbook*.

Corporate Taxes/GDP

Income from corporate taxes as a percentage of GDP. The data are published in various editions of *Revenue Statistics of OECD Countries*. We are grateful to John Ashworth for supplying us with the data.

by

**Markus Leibrecht and Christian Bellak**

## **Abstract**

In line with previous literature this paper finds that strict employment protection legislation has a negative impact on the volume of inward Foreign Direct Investment. Rigid labor markets result in high adjustment and exit costs which deter foreign investments. We also find that the deterrent effect of inflexible labor markets is larger for industries with relatively high shares of low-skilled workers employed. Our findings are consistent with the view that governments can support structural change by tightening labor market regulations which especially deters inflows of FDI into low-skill industries. To avoid a drop in high-skill FDI host countries should simultaneously improve other location factors especially relevant for the latter.

## Non-Technical Summary

A flexible labor market with low levels of employment protection is commonly perceived to provide an environment conducive to investment, employment and structural change. Many countries have therefore increased the flexibility of their labour markets during the past decades. An important element in the flexibilization of the labor markets is the degree of employment protection legislation. Employment protection encompasses regulations, either legislated or written in labor contracts that limit the employer's ability to hire or fire workers without delay or cost

Frequently, a positive relationship between labor market flexibility, a low degree of employment protection legislation, and Foreign Direct Investment (FDI) attraction has been proposed. This positive relationship is based on the view that strict employment protection legislation imposes exit costs for firms which - *ceteris paribus* - hamper inward FDI due to a reduction of an investment's profitability.

It is conceivable that higher exit costs due to strict employment protection legislation might be of particular relevance for FDI in industries which are highly mobile and less committed to a particular host location. Such industries, often termed "footloose industries", are especially sensitive to changing comparative advantage or changes in production cost. High exit costs prevent these industries from adjusting to such changes. These industries continuously seek for low labor cost locations and employ a rather large share of low skilled workers. Thus, it is likely that the negative impact of strict employment protection regulations on FDI *inter alia* depends on an industry's skill intensity.

The current study investigates the relationship between employment protection legislation and FDI in a panel of major host countries for inward FDI at the industry level. We add to the existing literature by testing the conditional hypothesis that the impact of strict employment protection legislation on FDI differs across industries due to differences in the skill composition of the workforce. Our prior expectation is that tight employment protection legislation will affect FDI more negatively in mobile industries with a higher share of low-skilled employment due to the greater importance of exit costs.

The sample used in this panel econometric study includes ten manufacturing sectors in 11 host countries for FDI for the period 1995-2005 and controls for a large number of determinants of FDI. In line with previous literature this paper finds that employment protection legislation, especially regulations towards regular employment, has a negative impact on the volume of inward Foreign Direct Investment. Yet, we also find that the deterrent effect of inflexible labor markets is predominately given for industries with relatively high shares of low skilled workers employed. This result is consistent with the view that high exit costs due to strict employment protection legislation matters particularly for mobile industries like the textile, food and wood industries which continuously seek for low labor cost locations.

## I. INTRODUCTION

Jurisdictions try to attract Foreign Direct Investment (FDI) by offering favorable location factors distinguishing them from competitor countries. A vast empirical literature exploring the determinants of FDI has emerged (e.g. Fontagné and Mayer 2005 for an overview). The results generally imply that both, market- and cost-factors matter for FDI attraction. Within the group of cost-factors labor-related costs are important. Costs of this type not only comprise directly measurable factors like wage costs (i.e. compensation to employees and social security contributions) but also more indirect costs stemming from the inflexibility of labor markets. Inflexibility of the labor markets creates costs for Multinational Enterprises (MNEs), since it might prevent profit maximizing adjustment of the labor force in the short-run.

Yet, although most FDI studies take wage costs into account, empirical studies exploring the relationship between labor market inflexibility and FDI have emerged only recently (see section 2 for an overview). This empirical literature is in favor of a negative effect of inflexible labor markets on FDI decisions of MNEs. Put differently, a positive relationship between labor market flexibility and FDI attraction is frequently proposed. This positive relationship is based on the view that rigid labor markets impose adjustment and exit cost which - *ceteris paribus* - hamper inward FDI due to a reduction in an investment's profitability (see Haaland et al. 2003; Nicoletti et al. 2003).<sup>1</sup>

The mechanisms in which exit costs in form of labor market rigidities affect the location and scale of FDI have been formally modeled by Haaland et al. (2003) based on the assumption of an uncertain environment. Moreover, the studies of Görg (2005) and Dewitt et al. (2009) explore the presence of amplifying effects of a country's riskiness and investment costs on the FDI impact of rigid labor markets.

However, it is conceivable that the negative impact of high adjustment and exit costs due to rigid labor markets on FDI is amplified by a host location's low-skill intensity: High adjustment and exit costs in form of rigid labor markets prevent firms from reacting to changes in comparative advantage and location factors. As the supply of low-skilled labor is

---

<sup>1</sup> It has to be stressed that another argument -theoretically established and empirically tested by Dewitt et al. (2009) - relates to domestic anchorage, i.e. the decision whether to engage in FDI. According to this argument, a high domestic level of employment protection tends to discourage outward FDI (anchoring effect of employment protection legislation). This is, however, not the argument here. We are rather concerned with "pull effects" of lax employment protection legislation due to low adjustment and exit costs.

abundant compared to that of high-skilled labor<sup>2</sup> it is likely that FDI into low-skill intensive industries is more sensitive to such changes in comparative advantage or location factors. Therefore high adjustment and exit costs might be of greater relevance for MNEs undertaking FDI in low-skill industries leading to a larger negative impact of rigid labor markets on FDI into low-skill intensive industries.<sup>3</sup> On the contrary, high-skilled labor is relatively scarce and thus higher search costs imply a lower sensitivity of FDI into high-skill industries to alterations in the locational quality.

Although the inflexibility of the labor market can arise from various labor market institutions we focus in this paper on a country's employment protection legislation which is the central part of the legal stipulations towards the labor market.<sup>4</sup> Employment protection encompasses regulations, either legislated or written in labor contracts that limit the employer's ability to hire or fire workers without delay or cost (Pissarides 2001; OECD 2004).

Labor standards and employment protection legislation in particular are largely in the realm of nation states. Thus, employment protection legislation is an instrument which allows jurisdictions to compete for FDI. Moreover, countries typically differ in their preferences for labor standards. Table 1a shows the level of employment protection legislation in selected OECD / EU countries<sup>5</sup>, based on the overall summary index (version 1) developed by the OECD (see OECD 1999 and 2004). This index captures regulations towards both, regular and temporary employment. The index ranges from zero (very low labor market protection) to 6 (very high labor market protection).

---

<sup>2</sup> Low skilled (untrained) labor is frequently described as a type of a location's "natural asset" – in contrast to more scarce "created assets" like skilled (trained) labor (see e.g. Dunning and Narula 1995).

<sup>3</sup> While in principle, low-skilled labor is employed within certain segments of every industry, it is also possible to differentiate between industries (see Peneder 2007 for a widely used industry classification) and rank them by their skill intensity. Typical examples of low-skill intensive industries are the food, textiles and the wood industries.

<sup>4</sup> Besides employment protection legislation the trade union density and coverage, the level of wage bargaining and the taxation of labor income are frequently used to characterize the flexibility of labor markets.

<sup>5</sup> The choice of countries and years is dictated by data quality and quantity (see section 3 for additional details).

Table 1a: Stringency of overall employment protection legislation in selected countries

	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005
AUT	2.21	2.21	2.21	2.21	2.21	2.21	2.21	2.21	1.93	1.93	1.93
CZE	1.90	1.90	1.90	1.90	1.90	1.90	1.90	1.90	1.90	1.90	1.90

GBR	0.60	0.60	0.60	0.60	0.60	0.68	0.68	0.75	0.75	0.75	0.75
USA	0.21	0.21	0.21	0.21	0.21	0.21	0.21	0.21	0.21	0.21	0.21

The USA and GBR have the lowest labor market standards in force throughout the sample period. The strictest regulations are stipulated in FRA, GER and SVN. Table 1a shows that 6 countries (AUT, FIN, GER, NLD, SVK, SVN) have substantially eased their employment protection legislation over time. Three countries (FRA, HUN and GBR) have increased and in two countries (CZE and USA) the index stays constant. Among the latter two groups are those countries which already had comparable lax employment protection legislation in force in 1995 (i.e. HUN, GBR, USA).

Table 1b: Stringency of employment protection legislation for regular employment

GBR	0.95	0.95	0.95	0.95	0.95	1.12	1.12	1.12	1.12	1.12	1.12
USA	0.17	0.17	0.17	0.17	0.17	0.17	0.17	0.17	0.17	0.17	0.17

Tables 1b and 1c depict the developments of the sub-indices capturing regulations towards regular and temporary employment. Three countries (NLD, SVK and SVN) have eased legislation for both types of employment. Interestingly, NLD and SVK have especially eased regulations towards temporary employment and SVN those towards regular employment. Two countries have tightened their regulation towards temporary employment over time (HUN and GBR) and the index for regular employment has soared in FRA and GBR. Furthermore, the tables show that GER has eased regulations towards temporary employment with unchanged regulations for regular employment and vice versa for AUT and FIN.

Table 1c: Stringency of employment protection legislation for temporary employment

Taken together, Tables 1a-c signal that a wide variety of levels of employment protection from which potential foreign investors may choose exists. Moreover heterogeneous developments over time are given.

Against this background the current study investigates the relationship between rigid labor markets in form of strict employment protection legislation and FDI in a panel of major host countries for inward FDI-stock at the industry level. We add to the existing literature by testing the conditional hypothesis that the negative impact of strict employment protection legislation on FDI differs across industries due to differences in the skill composition of the workforce. Our prior expectation is that the adverse effect of rigid labor markets on FDI is larger in industries with a higher share of low-skilled employment due to the greater importance of adjustment and exit costs.

In line with previous literature we find that employment protection legislation, especially stipulations towards regular employment, has a negative impact on FDI. However, we also find evidence that the deterrent effect of inflexible labor markets is larger for industries with relatively high shares of low-skilled workers employed.

The paper is structured as follows: Related empirical literature is summarized in section II. Section III. describes the empirical methodology applied and the data used. Section IV. presents the results and section V. concludes.

## II. REVIEW OF RELATED EMPIRICAL LITERATURE

This section briefly summarizes main features of related studies. Haaland et al. (2003) use firm level data on subsidiaries of Western MNEs located in the manufacturing sector in three Central and East European countries (CEECs) for the period 1994 to 1997 to test the validity of their theoretical exit cost model. They find that labor market flexibility, measured by the excess job reallocation rate has a significant negative impact on the FDI decisions of MNEs.

Javorcik and Spatareanu (2005) study the importance of labor market characteristics using firm level data covering the period 1998 to 2001. Their sample includes firms from Western and Eastern European host countries of FDI. As proxies for labor market flexibility they use data from the Global Competitiveness Report as well as data compiled by Djankov et al. (2001). Overall, Javorcik and Spatareanu (2005) find that the higher the flexibility of the labor market in the host country the more MNEs invest in the country.

Görg (2005) studies to what extent labor market regulations matter for the location of US outward FDI-stocks in manufacturing in 33 host countries over the period 1986 to 1996. The analysis is based on data from the Global Competitiveness Report to proxy labor market flexibility. Görg (2005) concludes that tight labor market regulation has a negative impact on FDI location decisions. Moreover, Görg (2005) explores whether the riskiness of a country amplifies the negative effect of tight labor market regulations as argued by Haaland et al. (2003). Yet, he does not find any amplifying effect.

Benassy-Quéré et al (2007a) apply a gravity model framework to analyze the impact of institutions in a broad sense on FDI. They relate bilateral FDI-stocks to various institutional variables for a broad range of countries, mainly developing countries. Among the variables analyzed, three measures for the degree of labor market regulation are included. These proxies are taken from the Fraser Institute database and the Institutional Profile database of the French Ministry of Finance. For two of these three variables Benassy-Quéré et al (2007a) find a significant negative impact on FDI. However, the coefficient of the third variable, which proxies the regulation of the labor market, enters insignificantly in their empirical model. Overall, however, they conclude that labor market rigidity has an adverse effect on FDI.

Benassy-Quéré et al (2007b) analyze sector-level data on US outward FDI-stocks for the period 1994 to 2002 in 18 Western and Eastern European countries. They also use data from the Fraser Institute as proxies for labor market flexibility and find only weak evidence for a

significant impact of labor market flexibility on FDI. Their proxy for labor market flexibility is significant only in a few cases and in these cases it enters with a positive coefficient.

Radulescu and Robson (2008) explain FDI-flows and also find support for the hypothesis that the strictness of employment protection legislation has a negative effect on FDI. They base their analysis on a sample of 19 OECD countries for the period 1975-1997. Their proxy for stringency of employment protection legislation is based on the Blanchard and Wolfers (2000) index.

Gross and Ryan (2008) find that employment protection matters in the foreign location choice of Japanese investors. There is a clear negative impact from strict legislation of regular employment on FDI-related employment size while the impact of the legislation on temporary employment is much weaker. They use the OECD index in their analysis.

Another study also applying the OECD index is Leibrecht and Scharler (2009). These authors use a panel of bilateral FDI-flows to seven CEECs over the period 1995-2004 and find that tight employment protection legislation does not exert a statistically significant impact on FDI once a proxy for unit labor costs is included in their empirical model. They conclude that the labor markets in the CEECs are not rigid enough to impose sizable exit costs. They argue that the low level of employment protection is also due to the still weak enforcement of labor laws in CEECs.

Finally, Dewitt et al. (2009) provide estimates for the impact of differences in employment protection legislation between home and host countries of FDI. Based on an analysis of bilateral outward FDI-stocks of OECD countries for the period from 1986 to 1995 they find a negative impact of an increasing employment protection legislation differential between home and host country. They apply the same measure for labor market flexibility as Görg (2005) as well as the OECD index for employment protection stringency. Dewitt et al. (2009) also explore whether the negative impact of an increasing employment protection legislation differential is amplified by an increase in the level of investment costs (cost of capital index). However, they do not find such an amplifying effect.

### III. EMPIRICAL MODEL AND METHODOLOGY, VARIABLES AND DATA ISSUES

#### 1. Empirical Model and Methodology

The current study is based on inward FDI-stocks in industrial sectors. The empirical model relates the logarithm of the inward FDI-stock of country  $i$  and industry  $j$  in year  $t$  to a set of location factors:

$$\ln\text{FDI}_{ijt} = b_1 + b_2X_{it} + b_3Z_{ijt} + b_4I_{ijt} + c_t + a_{ij} + e_{ijt} \quad (1)$$

The matrix  $X_{it}$  contains FDI-relevant location factors which vary over countries and over time and  $Z_{ijt}$  includes variables varying over time and over country-industry pairs. The former reflect the economic environment which is the same across all industries, while the latter group of variables reflects specific industry conditions. The former matrix includes different proxies for a host country's level of employment protection legislation (henceforth  $\text{EPL}_{it}$ ). The latter matrix contains a variable (henceforth  $\text{HLS}_{ijt}$ ) signaling the low-skill intensity of a particular industrial sector-country pair. Note, the variables contained in matrices  $X_{it}$  and  $Z_{ijt}$  are specified in logs (to reduce the impact of outliers) and enter in a one-year lagged form (to consider that contemporary FDI reacts to certain information on location factors with a time lag (see Bevan and Estrin 2004) and to account to some degree for endogeneity (see Wooldridge 2002)<sup>6</sup>).

$c_t$  denotes a matrix of  $(T - 1)$  time dummies and  $a_{ij}$  are  $(n - 1)$  country-industry-pair-specific fixed effects capturing the impact of time-invariant country, industry and country-industry factors.  $e_{ijt}$  is the remainder error term.

To test the hypothesis that the effect of strict employment protection legislation on FDI differs across industries due to differences in the skill composition of the workforce we include an interaction term between  $\text{EPL}_{it}$  and  $\text{HLS}_{ijt}$  in the empirical model. The vector  $I_{ijt}$  captures this interaction effect.

The use of interaction terms is justified whenever conditional hypotheses are tested (e.g. Brambor et al. 2006). Including an interaction effect in our empirical model allows us to

---

<sup>6</sup> Note, to explore the importance of the endogeneity issue we also apply an Arellano-Bond-type-GMM estimator as a robustness check (cf. Table 6).

directly explore the impact of  $EPL_{it}$  on  $FDI_{ijt}$  at various levels of  $HLS_{ijt}$ .<sup>7</sup> In particular, based on Equation 1 the effect of  $EPL_{it}$  on  $FDI_{ijt}$  is derived as follows:

$$\delta \ln FDI_{ijt} / \delta \ln Epl_{it} = b_2 + b_4 \ln HLS_{ijt} \quad (2)$$

Equation 2 contains several important aspects for the interpretation of interaction models. First, it is evident that coefficients in interaction models (here  $b_2$  and  $b_3$ ) no longer show the marginal effect of the variables entering the interaction effects. Specifically, coefficient  $b_2$  captures the effect of a change in  $EPL_{it}$  if  $\ln HLS_{ijt} = 0$ . That is, this coefficient shows the impact of  $EPL_{it}$  if only higher skilled workers are engaged in the production process. Thereby, one should bear in mind that  $\ln HLS_{ijt} = 0$  if  $HLS_{ijt} = 1\%$ . Yet, the minimum value of  $HLS_{ijt}$  in our sample is about 4.3% and the mean value is about 22%. Thus, the value of coefficient  $b_2$  is per se not meaningful. Rather, one needs to evaluate the marginal effect of  $EPL_{it}$  on FDI at different values of  $HLS_{ijt}$  multiplied by coefficient  $b_4$ . Coefficient  $b_4$  signals how the marginal impact of  $EPL_{it}$  on  $FDI_{ijt}$  changes if more low-skilled workers are employed.

A second aspect concerns the statistical significance of coefficients in interaction models. Specifically, it is likely that  $EPL_{it}$  has a statistically significant impact on FDI at meaningful levels of  $HLS_{ijt}$  even if  $b_2$ ,  $b_4$  or both coefficients are not statistically different from zero (see Brambor et al. 2006 for details). To cope with this possibility we also present graphs showing not only the marginal effect of  $EPL_{it}$  on FDI at various levels of  $HLS_{ijt}$  but also its statistical significance (also see Wooldridge 2003, p. 194f on this issue).

To reduce the possibility of an omitted variable bias and to explore the robustness of our results to inclusion and exclusion of variables we apply a “general-to-specific-approach” starting with the most general model (including all location factors considered), the full model, and testing down until only statistically significant variables remain. Note, that we generally conduct one-sided tests with the alternative hypothesis based on the expected sign of the coefficient (cf. Table 2). The significance of coefficients with an *a priori* ambiguous sign is based on two-sided tests. Standard errors are calculated using a non-parametric

---

<sup>7</sup> To model conditional hypotheses via interaction effects receives increasing attention in the empirical literature. For instance, Dewitt et al. (2009) and Görg (2005) also use interactions effect in their analysis.

bootstrap approach over clusters (country-industry-pairs) and are thus fully robust with respect to heteroscedasticity and serial correlation.

## 2. Variables and Data issues

### i. Dependent variable: $\ln\text{FDI}_{ijt}$

We use the inward FDI-stocks of 10 manufacturing sectors in millions of current Euro as dependent variable. The data is taken from Eurostat's New Cronos database and the wiiw Database on Foreign Direct Investment (for CEECs).

### ii. Variables of main interest

#### a. Interaction between $\ln\text{EPL}_{it}$ and $\ln\text{HLS}_{ijt}$ : $I_{ijt}$

The interaction term is defined as the product of  $\ln\text{EPL}_{it}$  times  $\ln\text{HLS}_{ijt}$ . Given our prior expectations that tight employment protection legislation will affect FDI more negatively in low-skill intensive industries the coefficient of  $I_{ijt}$  should be negatively signed.

#### b. Employment protection legislation: $\text{EPL}_{it}$

We proxy the stringency of  $\text{EPL}_{it}$  with the indices developed and discussed in OECD (1999 and 2004). For Slovenia the data are obtained from Leibrecht and Scharler (2009; Table 2). Three different  $\text{EPL}_{it}$  indices are used: an overall summary index (henceforth  $\text{Eplov}_{it}$ ), a sub-index for protection of regular workers ( $\text{Eplreg}_{it}$ ) and a sub-index for regulations towards temporary employment ( $\text{Epltemp}_{it}$ ).

The methodology for calculating the three  $\text{EPL}_{it}$  indicators is detailed in OECD (2004) so we do not elaborate on this issue here. Yet, it is important to stress that we use version 1 of the  $\text{EPL}_{it}$  index. The OECD has also developed a version 2 index which captures regulations towards collective dismissals. However, due to lack of data we do not use the version 2 index in our analysis. Specifically, annual time series data for the version 1 index is available from 1985-2008 whereas version 2 indices are available for most countries from 1998 onwards

only. The version 1 index for  $Epl_{it}$  is calculated as unweighted average of the two sub-indices, which are themselves based on a weighted average of different variables.<sup>8</sup>

Advantages of the OECD index over other proxies for the stringency of employment protection legislation are that it is available in panel data form; that it is derived on an internationally comparable basis and that sub-indices, isolating the importance of different dimensions of labor market rigidity, are available.

Given that a higher level of  $EPL_{it}$  (that is tighter employment protection regulations) implies higher adjustment and exit costs it should be negatively related with FDI independently of an industry's skill intensity (i.e a negative direct effect of  $EPL_{it}$  is expected).

c. Share of low-skilled workers employed:  $HLS_{ijt}$

The share of low-skilled hours in total hours worked,  $HLS_{ijt}$ , is used as a proxy for the low-skill intensity of an industry. Skill variables are frequently used independently of any  $EPL_{it}$  to disentangle the underlying motive for FDI; i.e. whether it is vertically or horizontally motivated (e.g. Markusen and Maskus 2002; Davies 2008). In the first case the coefficient of  $\ln HLS_{ijt}$  should be positive. In this case MNEs exploit differences in factor endowments. In the second case, the sign should be negative, as firms duplicate plants (e.g. Barba Navaretti and Venables 2004, Chap. 2). Thus, in principle the sign of the  $\ln HLS_{ijt}$  coefficient is indeterminate *a priori*. However, the majority of empirical studies finds that FDI is more horizontally than vertically motivated, especially in case of OECD countries (e.g. Davies 2008; Bloningen et al. 2003). Thus, we expect the coefficient of  $\ln HLS_{ijt}$  to carry a negative sign. Data is taken from the EUKLEMS database.

**iii. Control variables**

The choice of control variables included in matrices  $X_{it}$  and  $Z_{ijt}$  is done with a focus on FDI theories (see Faeth 2009 for an overview). However, FDI theories provide only a rough guide for the choice of control variables. Therefore we base our selection of these variables mainly on related empirical studies (e.g. Markusen and Maskus 2002; Görg 2005; Benassy- Quéré et al. 2007a, b).

---

<sup>8</sup> Note that for Slovenia the available  $Epl_{it}$  follows the version 2 index. However, as the version 1 index is the simple unweighted average of  $Epl_{reg,it}$  and  $Epl_{temp,it}$  an unweighted average of these two variables is used as  $Epl_{it}$  in case of Slovenia.

Specifically, we include a proxy for market size ( $Pot_{it}$ ), GDP per capita ( $GDPcap_{it}$ ), the average effective tax rate on corporate profits ( $EATR_{it}$ ), public R&D expenditures as percent of GDP ( $Govgerd_{it}$ ), the political risk level ( $Risk_{it}$ ), the macroeconomic risk level ( $Cpi_{it}$ ), the information and communication (ICT) infrastructure endowment ( $Ict_{it}$ ), and the level of legal barriers to FDI ( $Freefdi_{it}$ ) in the matrix  $X_{it}$ . Control variables entering  $Z_{ijt}$  are labor costs ( $Labcost_{ijt}$ ) and labor productivity ( $Labprod_{ijt}$ ).

Variable  $Pot_{it}$  captures market size, and is expected to be positively correlated with FDI. The sign of the coefficient of  $GDPcap_{it}$  might be considered as ambiguous *a priori* (e.g. Benassy-Quéré et al. 2007a), pointing towards its role as a “catch-all” variable: On the one hand it might represent effects of labor costs on production costs (e.g. Mutti and Grubert 2004), implying a negatively signed coefficient. On the other hand, it captures positive effects on an FDI’s profit level via a favorable infrastructure endowment (e.g. Mutti 2004), a country’s purchasing power and labor productivity (e.g. Mutti and Grubert 2004), as well as better institutions and less economic and political risk (e.g. Benassy-Quéré et al. 2007a).

As we include most of these underlying variables in our model  $GDPcap_{it}$  is intended to capture FDI effects of an increasing purchasing power in our application (also see Görg 2005). Thus, a positively signed coefficient is expected.

Labor costs partly reflect to what extent FDI location decisions are driven by efficiency considerations. An increase in  $Labcost_{ijt}$ , *ceteris paribus*, increases production costs. We therefore expect a negatively signed coefficient. In addition, an increase in  $Labprod_{ijt}$  should impact positively on FDI, not least via its favorable impact on unit production costs.

The change in the consumer price index,  $Cpi_{it}$ , is used as a proxy for macroeconomic risk as a high inflation rate indicates macroeconomic uncertainty which deters FDI. Yet, as our endogenous variable is measured in nominal terms higher inflation rates might also have a positive impact on the volume of FDI (Buch and Lipponer 2007). Thus the sign of this variable’s coefficient is ambiguous *a priori*.

Similarly to  $Cpi_{it}$  a higher level of political risk,  $Risk_{it}$ , should impact negatively on FDI. Yet, due to the particular definition of the measure of  $Risk_{it}$  used we expect a positively signed coefficient. The variable  $Freefdi_{it}$  is intended to capture legal barriers to inward FDI. Legal barriers to FDI are lower the higher the score of  $Freefdi_{it}$ . Thus, we expect a positive sign for this variable.

The variable  $EATR_{it}$  is a summary measure for the taxation of FDI proceeds capturing both, the tax burden on a very profitable as well as on a marginal investment. More specifically, the after-tax profit from FDI is directly determined by the average tax rate (see Devereux and Griffith 1998a). A higher  $EATR_{it}$  implies lower after-tax profits and thus lower incentives to invest in a particular location. Thus, a negatively signed coefficient is expected.

As an increasing part of FDI constitutes R&D related activities (see e.g. Guimón 2009) a high level of public expenditures on R&D should be relevant for an MNE's location decision. Specifically, a country's R&D level can be considered as a type of public good with positive spill-over effects on firms. These in turn increase productivity without causing additional costs and lead to a higher profitability of an investment. Thus, an increase in the public R&D expenditures in GDP ( $Govgerd_{it}$ ) should have a positive impact on FDI.

A country's endowment with material infrastructure is generally considered to have a positive impact on FDI. Thereby a favorable endowment with ICT-infrastructure has been frequently shown to be particularly relevant for FDI attraction (e.g. Bellak et al. 2009; Mollick et al. 2006). Therefore we include a variable,  $Ict_{it}$ , capturing a country's endowment with ICT-infrastructure in the empirical model. However, it should be stressed, that other FDI relevant infrastructure components, like the transport or the power generation infrastructure, are captured to some extent by  $GDPcap_{it}$ . Moreover, as these infrastructure components are only slowly evolving over time, they also might be captured by the country-industry-specific fixed effects,  $a_{ij}$ , included in our empirical model.

#### iv. Data Issues

Our sample includes the countries listed in Tables 1a-c for the period 1995-2005 and in 10 industrial sectors DA, DB, DD/DE, DG, DH, DJ – DM (Nace Revision 1 classification).<sup>9</sup> Focusing on inward FDI-stock to the manufacturing sector implies that substantial shares of employment and of gross fixed capital formation in the host countries are covered by our analysis: The minimum share in domestic employment (in manufacturing sector national total<sup>10</sup>) is 6% in GER in 1998 and the maximum share is 44% in SVK in 2005; the minimum

<sup>9</sup> Industries DA, DB, DD/DE are typical examples of industries employing rather high shares of low-skilled workers. The mean values of  $Hls_{ijt}$  (1995-2005) are 25%, 25% and 41%. In the other industries the corresponding values are lower ranging from 16% (DK-DM) to 20% (DJ and DH).

<sup>10</sup> See:

[http://stats.oecd.org/OECDStat\\_Metadata/ShowMetadata.ashx?Dataset=AFA\\_CALC\\_IN3&ShowOnWeb=true&Lang=en](http://stats.oecd.org/OECDStat_Metadata/ShowMetadata.ashx?Dataset=AFA_CALC_IN3&ShowOnWeb=true&Lang=en).

share in domestic gross fixed capital formation is 6.5% in FIN and the maximum share is 70% in HUN and NLD in 2005.

The choice of years and countries is predominantly driven by data issues. FDI and EUKLEMS data was available until 2005 and data from the EUKLEMS database is only available from 1995 onwards for a couple of countries. FDI data at the industrial level have many missing values for a range of countries (e.g. Greece, Japan, Portugal and Switzerland). Moreover data on several exogenous variables are lacking for some countries. Especially data on  $EATR_{it}$  was available at an internationally comparable basis only for the countries included plus Italy, Poland, Romania, Bulgaria and Croatia. However, these countries are excluded for the following reasons: Data on  $HLS_{ijt}$  for Italy is questionable as rather low percentages of low-skilled workers employed are shown in the EUKLEMS database for this country; Poland is an “outlier” in the type of FDI received -most FDI is going into the primary and the tertiary sector; EUKLEMS data are not available for Romania, Bulgaria and Croatia.

Table 2 summarizes the above discussions with respect to the variables used also including the rationale behind these variables. It provides the expected sign of the estimated coefficients, the data sources used and a detailed description of the measurement and definition of the variables. Note, that only for one variable the expected sign is ambiguous *a priori* ( $Cpi_{it}$ ). Table 3 includes some descriptive statistics for the variables used in the analysis and Table 4 shows their pairwise correlations. Some correlations are rather pronounced, especially those with  $GDPcap_{it}$  which is consistent with the “catch all” character of this variable. We check the sensitivity of the results to this correlation in our estimations by excluding  $GDPcap_{it}$  in one specification (see Table 6, M2).

Table 2: Variable rationale, variable description and summary statistics

Variable	Rationale	Exp. Sign	Definition	Source
$FDI_{ijt}$	Endogenous variable.		Inward FDI-stock of 10 manufacturing sectors in mn of current Euro	Eurostat's New Cronos database and wiiw Database on FDI (for CEECs)
$Pot_{it}$	Larger markets should experience more inward FDI. Opportunities to generate profits are higher.	+	Own market potential; calculated as follows: $POT = (GDP / \text{internal distance})$ GDP in mn of current Euro	Eurostat's New Cronos database; CEPII internal distance measures: <a href="http://www.cepii.org/anglaisgraph/bdd/distances.html">http://www.cepii.org/anglaisgraph/bdd/distances.html</a>
$GDPcap_{it}$	Captures positive effects of higher purchasing power on FDI.	+	GDP per capita in Euro15-PPP	Eurostat's New Cronos database
$EATR_{it}$	A higher effective tax rate should decrease inward FDI, since it directly impacts negatively on the after-tax profit level of an FDI.	-	Effective average tax rate (in percent)	Own calculations based on Devereux and Griffith 1998b; assumptions follow Devereux and Griffith as well as the IFS data available under <a href="http://www.ifs.org.uk/publications.php?publication_id=3210">http://www.ifs.org.uk/publications.php?publication_id=3210</a> ; raw tax data are taken from the European Tax Handbook and KPMG's Corporate Tax Rate Surveys
$Govgerd_{it}$	Higher R&D expenditures in GDP should encourage inward FDI due to knowledge spill-over effects.	+	Government-financed expenditures on R&D in percent of GDP	OECD's Main Science and Technology Indicators database
$Freefdi_{it}$	Higher legal barriers towards FDI directly imply less inward FDI.	+	index ranges from 0 – 100 higher value means less restrictions	The Heritage Foundation <a href="http://www.heritage.org/index/faq.aspx">http://www.heritage.org/index/faq.aspx</a>
$HLS_{ijt}$	Depending on the motive of FDI, this	-	Share of low-skilled employees in total	EUKLEMS database

Variable	Rationale	Exp. Sign	Definition	Source
	variable signals either higher incentives to fragment production (vertical FDI) or lower possibilities to duplicate plants (horizontal FDI). Yet, empirically horizontal FDI is dominating.		employment	
Labcost <sub>ijt</sub>	Higher labor costs imply higher production costs and thus lower FDI.	–	Compensation of employees (in millions of Euro) / Total hours worked by employees (millions)	EUKLEMS database
Labprod <sub>ijt</sub>	Higher labor productivity attracts FDI via its favorable effect on production costs.	+	Gross value added in Euro15-PPP/ Total hours worked	EUKLEMS database
Ict <sub>it</sub>	Larger ICT-infrastructure endowment lowers production costs and thus increases FDI.	+	Sum of telephone mainlines, mobile phone subscribers, internet connections and personal computers per 1000 inhabitants	World Banks's World Development Indicators database
Epl <sub>it</sub> *	Tighter employment protection legislation increases adjustment and exit costs.	–	Indicators of the strictness of employment protection legislation (version 1) Scale: 0-6 with higher scores representing stricter regulation	OECD's Labor market statistics database; <a href="http://www.oecd.org/employment/protection">www.oecd.org/employment/protection</a> ; for SVN source is Leibrecht and Scharler (2009) Table 2
I <sub>ijt</sub> **	Stricter employment protection legislation matters particularly for industries with a large share of low-skilled workers employed.	–	Interaction effect between HLS <sub>ijt</sub> and the different types of Epl <sub>it</sub> *	See sources for HLS <sub>ijt</sub> and Epl <sub>it</sub>

Variable	Rationale	Exp. Sign	Definition	Source
Risk <sub>it</sub>	Politically riskier countries should receive less inward FDI due to higher uncertainty and larger possibilities of expropriation.	+***	Political risk ( 0 = high; 25 = low)	Euromoney
Cpi <sub>it</sub>	Riskier countries should receive less inward FDI due higher uncertainty; Yet one has to bear in mind that the endogenous variable is denominated in nominal terms.	?	Change in consumer price index	Eurostat's New Cronos database

Notes: \* Epl<sub>it</sub> captures all three proxies for employment protection legislation used in the analysis; \*\* interaction term of lnHLS<sub>ijt</sub> with each of the three indices contained in Epl<sub>it</sub>;

## IV. RESULTS

We start by commenting briefly on the control variables. The remainder of the results section is organized by the three types of  $Epl_{it}$ .

### 1. Control variables

Table 6 (M1 and M4) shows that we control for many different cost- and market-related determinants of FDI. In particular, Table 6 implies that the countries in our sample are host countries of FDI where (i) political and macroeconomic risk does not play a role; where (ii) relevant restrictions on FDI hardly exist anymore and where (iii) FDI are not productivity driven, but primarily labor cost driven. FDI directed to these countries reacts significantly positive to an increase in market size and purchasing power, as well as to an improvement of ICT-infrastructure and significantly negative to an increase in labor costs and taxes. These results are not implausible when compared to related empirical literature on the determinants of FDI (e.g. Bevan and Estrin, 2004). Moreover, the coefficients, which all represent elasticities, are of an economically meaningful size. Note, that Model (M1) includes the variable  $GDPcap_{it}$ , which due to its nature described above, may partly reflect other location factors included, e.g. infrastructure endowment or the risk level. Therefore, we re-estimate (M1) by excluding  $GDPcap_{it}$ . (M2) shows that dropping  $GDPcap_{it}$  changes only little.

### 2. Variables of main interest

Starting with  $Epl_{it}$  Table 6 suggests that strict employment protection has a direct, not interacted, negative effect on inward FDI-stock (see M1-M3).<sup>11</sup> The size of the coefficient on  $Epl_{it}$  (M1 -0.48 and similar sizes of coefficients in M2 and M3) implies that a 1% increase in the index of employment protection would lead to an almost 0.5% reduction in inward FDI-stocks. These results are consistent with the findings of prior empirical literature (see section 2).<sup>12</sup>

Before we turn to the interaction effect, a few words on the second variable which constitutes the interaction effect, i.e.  $HLS_{ijt}$ , are in order. Referring to Table 6 (M1-M5)  $\ln HLS_{ijt}$

<sup>11</sup> Note that model (M1) contains the full set of controls variables whereas stepwise exclusion of statistically insignificant variables leads to our preferred specifications (M3 and M5).

<sup>12</sup> For model (M3) the results of a bootstrapped Hausman-test (HT) is reported which shows that the  $H_0$  (i.e. Random Effects assumptions are valid) is rejected.

consistently carries a negative sign with an elasticity of 0.4-0.5. The negative sign points to the prevalence of horizontal FDI where firms duplicate their domestic activities abroad. This finding is plausible as the host countries included in our sample receive most of inward FDI from countries of similar level of development.<sup>13</sup>

The interaction effect,  $I_{ijt}$ , shows a negatively signed coefficient which is also statistically significant. Moreover, the F-test reported in Table 6 (M4 and M5) signals that the coefficients for  $\ln\text{Eplov}_{it}$  and  $I_{ijt}$  are jointly statistically significant different from zero at the 5% significance level, which underpins the effects derived. These results are consistent with the view that the impact of strict employment protection indeed increases with the share of low-skilled workers employed.

Note, that the coefficient on  $\text{Eplov}_{it}$  carries an unexpected positive sign in models (M4) and (M5). However, this coefficient shows the effect of a change in  $\text{Eplov}_{it}$  if  $\text{HLS}_{ijt} = 1\%$ . As already noted this value of  $\text{HLS}_{ijt}$  is not included in our sample. Moreover, as stressed by Kennedy (2005; example 8) it is not unusual that one of the interacting variables carries the “wrong” sign, with the model nevertheless showing the expected marginal effects over a meaningful range of sample values (cf. Figure 1).

As already stressed the marginal effect of  $\ln\text{Eplov}_{it}$  cannot be taken directly from the values given in Table 6 but needs to be calculated according to Equation 2 with changing values of  $\ln\text{HLS}_{ijt}$ . For instance, evaluated at the mean value of  $\ln\text{HLS}_{ijt}$  of about 2.95 the coefficients given in model (M5) imply that a 1% increase in  $\text{Eplov}_{it}$  would lead to a decrease in FDI by about 0.5%.<sup>14</sup> More generally, Figure 1 displays size and significance of the marginal effect of  $\ln\text{Eplov}_{it}$  across the range of sample values of  $\ln\text{HLS}_{ijt}$ . The effect is significantly negative in a statistical sense when  $\ln\text{HLS}_{ijt}$  is about 2.75 or above. In other words, about two-thirds of observations are in the region of significance. Moreover, the effect never turns positively significant.

Finally, as a robustness check, models (M3\_GMM) and (M5\_GMM) show results for  $\ln\text{Eplov}_{it}$ ,  $\ln\text{HLS}_{ijt}$  and  $I_{ijt}$  entering contemporaneously into matrices  $X_{it}$  and  $Z_{ijt}$ , respectively. Endogeneity is mitigated by using two-years and higher lagged values of these variables as instruments within an Arellano-Bond-type First Difference estimator. Moreover, the appendix to the paper contains a Figure A1 which is similar to Figure 1 but based on model

<sup>13</sup> Even the CEECs included in our sample are among the highest developed transition countries.

<sup>14</sup> Calculated according to Equation 2 as  $1.22 - 0.58 * 2.95$ .

(M5\_GMM). Models (M3\_GMM) and (M5\_GMM) as well as Figure A1 imply that our results remain qualitatively unchanged.<sup>15</sup> Thus, taken together our results suggest that a high value of  $Eplov_{it}$  deters FDI in general and in industries with high shares of low-skilled workers employed in particular.

Figure 1: Impact of  $\text{Eplov}_{it}$  on FDI as  $\text{HLS}_{ijt}$  changes

Source: Based on Stata code made available by Thomas Brambor:  
<http://homepages.nyu.edu/~mrg217/interaction.html#code>

As  $\text{Eplov}_{it}$  is a summary index it might hide structural differences, which are revealed by the underlying sub-indices,  $\text{Eplreg}_{it}$  and  $\text{Epltemp}_{it}$ . Table 7 includes the results.

Again starting with the model excluding the interaction effect (M6 as the preferred model), the coefficient on  $\text{Eplreg}_{it}$  is statistically significant and also carries a negative sign like

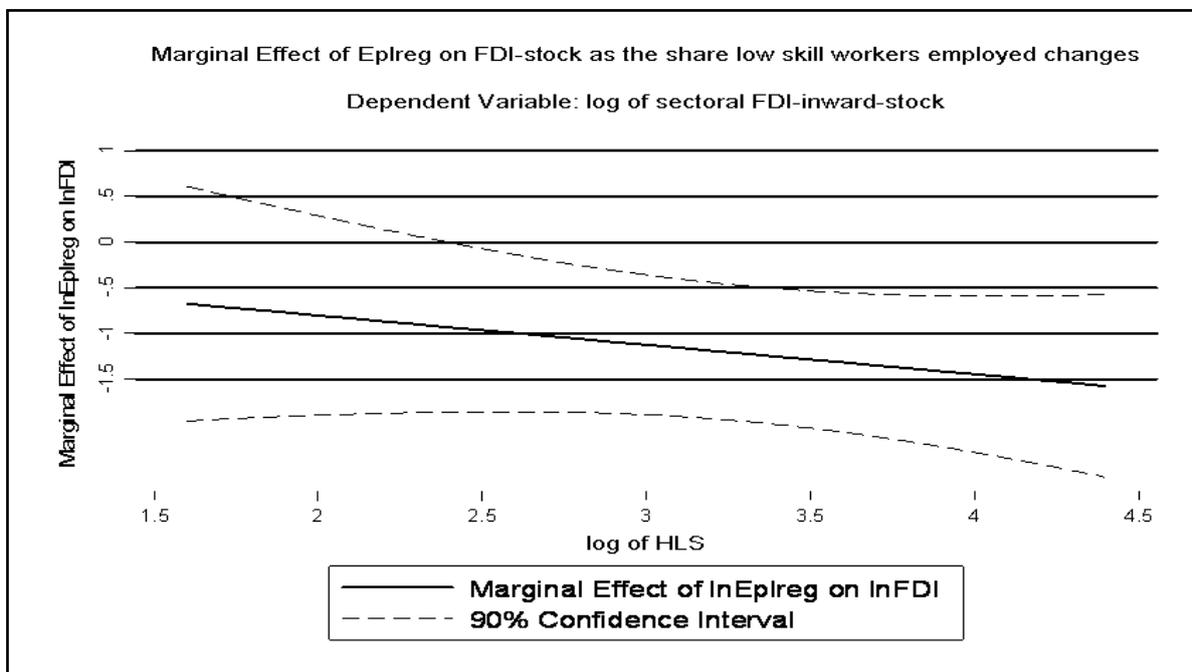

$Eplv_{it}$ , but implying a substantially higher elasticity. Thus, strict regulations towards regular employment have a significant direct effect on inward FDI.

Model (M7) in Table 7 shows the preferred specification with the interaction term included. Although none of the three coefficients of main interest is statistically significant this does not imply that no economically and statistically significant effect exists (cf. Figure 2) as outlined above and detailed in Brambor et al. (2006). Moreover,  $\ln Eplreg_{it}$  and  $I_{ijt}$  are jointly statistically different from zero.

The marginal effect of  $\ln Eplreg_{it}$  evaluated at the mean value of  $\ln HLS_{ijt}$  is  $-1.11$ .<sup>16</sup> Thus, evaluated at the mean value of  $\ln HLS_{ijt}$  the effect of  $Eplreg_{it}$  is larger than that of  $Eplv_{it}$ .

Turning to size and significance of the marginal effect of  $\ln Eplreg_{it}$  over different values of  $\ln HLS_{ijt}$ , Figure 2 clearly shows that – similar to  $Eplv_{it}$  – the marginal effect of  $\ln Eplreg_{it}$  is significant and negative for the majority of the sample values of  $\ln HLS_{ijt}$ . Only 16% of observations are outside the region of significance and the elasticity never turns significantly positive.

Figure 2: Impact of  $Eplreg_{it}$  as  $HLS_{ijt}$  changes

<sup>16</sup> Calculated according to Equation 2 as  $-0.16 + (-0.32 \cdot 2.95)$ .

The third indicator of  $Epl_{it}$  used in the analysis is  $Epltemp_{it}$ . In marked contrast to the previous results, the coefficient on  $\ln Epltemp_{it}$  is statistically not significant and has a substantially lower elasticity close to zero. Thus, regulations towards temporary employment seem not to have any impact on FDI. This result is in line with Gross and Ryan (2008) who conclude that although the protection of regular employment exerts a harmful effect on FDI, regulation with respect to temporary employment has a much weaker impact. More importantly, this result is not unexpected as the share of temporary employment in total employment remains below 15% in the countries in our sample (ILO 2008). Thus, the majority of labor contracts are on a regular basis.<sup>17</sup> This is consistent with the finding of a larger effect of  $Eplreg_{it}$  than  $Epltemp_{it}$  on FDI.

## V. CONCLUSIONS

Summarizing, for a country's overall regulations towards employment protection and for regulations towards regular employment the results confirm our expectations: the rigidity of labor markets matters for inward FDI-stock and the deterrent effect is larger in industries with high shares of low-skilled workers employed. Yet, for regulations towards temporary employment no impact on FDI is established. This is, however, not implausible given the arguments in the related empirical literature discussed above and the descriptive evidence presented.

Our findings suggest that governments can support structural change by tightening of labor market regulations. Such policies may lead to a change in the composition of manufacturing activities by deterring FDI into low-skill intensive sectors. Host country governments should simultaneously improve those location factors which are especially relevant for high-skill FDI (e.g. the economy's R&D intensity which is shown to have a positive impact on FDI). This has the potential to compensate investors into high-skill industries for higher labor-related costs and thus to stabilize the level of FDI into these sectors. Indeed, such policies have been used by several Asian countries (e.g. China, Taiwan, Singapore, Malaysia, South Korea) in order to climb up the ladder of production and product technologies (see e.g. Asian Development Bank 2004).

Finally, let us point out two aspects: First, one should bear in mind that the proxies for the degree of employment protection legislation used in this and earlier studies are often based on legal constraints that apply in host countries of FDI. Thus, they may not fully capture the degree of enforcement of employment protection across countries and over time. This is especially relevant in samples of heterogeneous countries as strict enforcement of labor laws needs well functioning labor tribunals. For example, in the CEECs the enforcement of

employment protection legislation is weak due to the limited capacities of the courts and labor inspectorates (see Leibrecht and Scharler, 2009).

Secondly, as most industries have segments of low- and high-skill activities, the sector view may be too broad (see Snower et al. 2009, p. 142) for analyzing the current issue. Yet, it is hoped that once more detailed micro-data become available, future research will be able to address this problem more thoroughly.

Due to geographic proximity and sizable Puerto Rican communities already present in the state, Florida has become a primary destination for in-migrants from Puerto Rico in recent years. Following a brief exposition of decennial census counts for 2000 and 2010, this article examines various aspects of Puerto Rican population growth in Florida – as well as for some other states – focusing especially on migration patterns; we also discuss some county-level patterns. The primary data source we use in this article includes 1-year estimates from the American Community Survey (ACS) from 2005 to 2016 as well as data from the 1-year Public Use Microdata Sample (PUMS) files of the ACS for those years. We close with comments about recent inflows from Puerto Rico to Florida following Hurricane Maria.

**Table 1. Puerto Rican Population in the United States, Puerto Rico, and the Top Five States**

	Puerto Rican Population				Numeric Change		Percentage Change	
	Census		ACS 1-year		Census	ACS	Census	ACS

Massachusetts	3.1	4.1	4.0	4.7	46.5	42.4	41.6	40.9

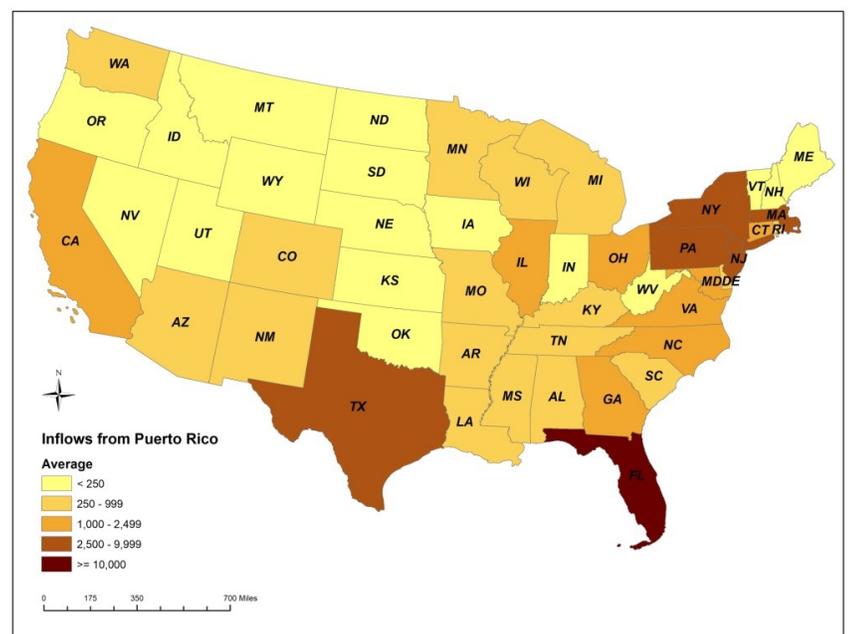

Table 1 shows that the number of Puerto Ricans living in the United State has increased by about 1.2 million (36%) between 2000 and 2010, while it decreased slightly in Puerto Rico. For comparison, Table 1 also displays the 1-year ACS estimates for 2010; while not identical, the 2010 1-year ACS estimates are generally quite close to the 2010 decennial census counts. For the United States, the 2000–2010 trend continued in 2010–2016, with the Puerto Rican population growing by another 750,000 (16%). The population declines accelerated in Puerto Rico, with the island’s population shrinking by about 300,000 (8%) since 2010. Among states, New York still has the largest resident population of Puerto Ricans, but it has hardly changed since 2000. In contrast, the Puerto Rican population living in Florida has grown rapidly since 2000, increasing by about 365,000 (76%) from 2000 to 2010, and by another 200,000 (24%) from 2010 to 2016. Other states with sizeable Puerto Rican populations include New Jersey, Pennsylvania, and Massachusetts; in all three states the Puerto Rican population increased more rapidly than in New York, though not as fast as in Florida. By 2016, about 3.38 million Puerto Ricans lived in the top 5 states, representing about 62% of all Puerto Ricans living on the U.S. mainland (the lower 48 states), Alaska, and Hawaii.

The bottom panel of Table 1 shows the shares of the Puerto Rican population of total population and of the Hispanic population. Between 2000 and 2016, the Puerto Rican share of total population increased for the nation overall as well as in Florida, Massachusetts, New Jersey, and Pennsylvania; it showed little change in New York. The Puerto Rican share of the Hispanic population increased only in Florida; it stayed about the same nationwide, and decreased in the other four states. The decreasing shares of Puerto Ricans among all Hispanics in New York, New Jersey, Pennsylvania, and Massachusetts mean that other Hispanic origin groups grew comparatively faster than the Puerto Rican population in those states.

### Inflows from Puerto Rico

We next examine the migration destinations of Puerto Ricans who moved to the United States mainland between 2005 and 2016. Figure 1 displays the average annual flows from Puerto Rico to each state over that period and gives us a picture of the geographic dispersal of the Puerto Rican migrants. Florida attracted the largest inflow from Puerto Rico. Other states with large inflows include several Northeastern states (New York, New Jersey, Pennsylvania, and Massachusetts), and Texas. In general, states east of the Mississippi recorded larger inflows than those in the western U.S., reflecting geographic proximity and earlier settlement patterns of the Puerto Rican population stateside.

**Figure 1. Average Annual Inflows from Puerto Rico to the Continental United States, 2005–2016**

As shown in Table 2, Florida's share (29%) of the total inflow from Puerto Rico to the United States between 2005 and 2016 far exceeded that of any other state. In fact, Florida's share was almost as large as the combined inflows to New York, Pennsylvania, Texas, and Massachusetts. New York still has the largest population of Puerto Ricans on the mainland (see Table 1). However, because of the much faster growth of the Puerto Rican population living in Florida, as well as that of several other states, New York's share of Puerto Ricans living in the United States has been declining over time, from about 31% in 2000 to 20% by 2016 (data not shown). Given these trends, it is possible that the 2017 ACS 1-year estimates, which are scheduled to be released in the fall of 2018, will show that Florida has become the state with the largest Puerto Rican population living on the mainland (see also the discussion about Hurricane Maria below).

**Table 2. The Top 10 Destination States for Migrants from Puerto Rico to the United States, 2005–2016**

Rank	State	Total Inflow	Share (in %)
1	Florida	242,134	29.0
2	New York	79,985	9.6
3	Pennsylvania	68,727	8.2
4	Texas	58,723	7.0
5	Massachusetts	50,231	6.0
6	New Jersey	44,360	5.3
7	Connecticut	29,809	3.6
8	Ohio	23,639	2.8
9	Georgia	22,438	2.7
10	California	20,555	2.5

Next, we focus in more detail on the migration flows from Puerto Rico to Florida. Figure 2 depicts the annual inflows from Puerto Rico to Florida between 2005 and 2016; these ranged from about 11,400 in 2005 to 24,000 in 2016, peaking at just over 31,000 in 2014. Although the 1-year ACS estimates fluctuate from year to year, the overall trend is upwards. In addition, the figure shows Florida's share of total inflows to the United States from Puerto Rico; it ranged from 24% (in 2010) to 36% (in 2014) over the period.

Figure 2. Annual Inflows from Puerto Rico to Florida, 2005–2016

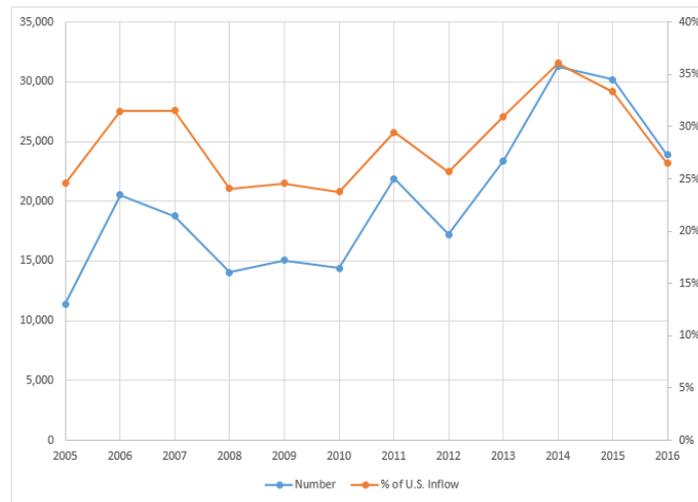

Figure 3 makes clear that migrants from Puerto Rico predominantly settled in Central and South Florida; the majority of counties in North Florida, in contrast, received fewer than 100 migrants on average per year. In fact, more than two thirds of all migrants from Puerto Rico to Florida moved to Central Florida, followed by South Florida (about 20%). Puerto Ricans are attracted to Central Florida due to the large population of Puerto Ricans already living in the area; the education system, job opportunities, and relatively inexpensive housing are further attractors. Orange County recorded the largest inflow of Puerto Ricans of all Florida counties between 2005 and 2016, as shown in Figure 3 and Table 3, followed by Osceola and Hillsborough counties. Rounding out the top five are Miami–Dade and Broward counties in South Florida.

Figure 3. Average Annual Inflows from Puerto Rico to Florida Counties, 2005–2016

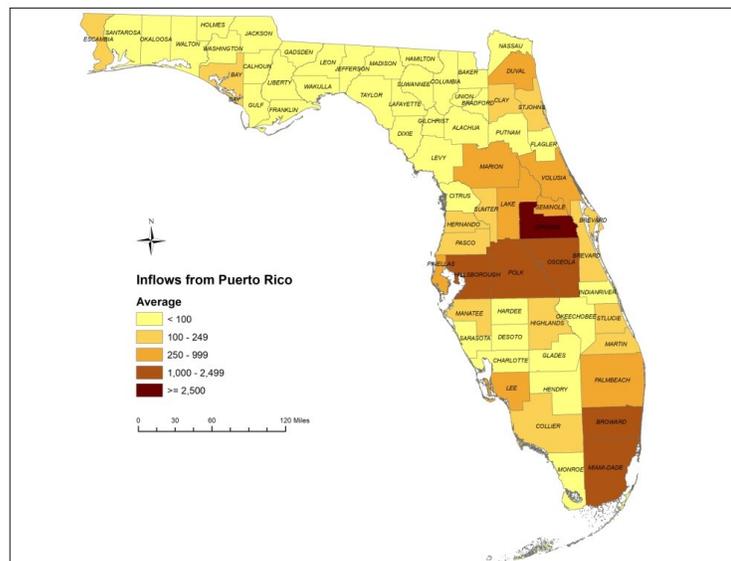

Table 3. The Top 10 Destination Counties for Total Inflows from Puerto Rico to Florida, 2005–2016

Rank	County	Total Inflow	Share (in %)
1	Orange	61,819	25.5
2	Osceola	29,949	12.4
3	Hillsborough	23,739	9.8
4	Miami-Dade	19,876	8.2
5	Broward	15,040	6.2
6	Polk	12,528	5.2
7	Volusia	9,151	3.8
8	Palm Beach	8,616	3.6
9	Pinellas	6,634	2.7
10	Seminole	6,329	2.6

Turning from Florida to the nation, Table 4 displays the 15 counties in the United States with the largest populations of Puerto Rican residents. Since the 1-year ACS estimates can fluctuate from year-to-year, we averaged three years of data to provide more stable results. We note that these are not identical to the 3-year ACS estimates, which have been discontinued in 2013. Table 4 shows estimates for 2005 to 2007 and 2014 to 2016; these represent the earliest and the most recent ACS data available. At the beginning of the period, four of the five boroughs of New York City – the Bronx, Brooklyn (Kings County), Manhattan (New York County), and Queens – were in top six; Cook County, Illinois, and Orange County, Florida were ranked third and fourth. By 2014–2016, while the Bronx remained in first place, Manhattan had dropped four spots to ninth, and Brooklyn fell from second to third rank. The Bronx, Brooklyn, and Manhattan recorded population decreases between 10% and 17% over the period, totaling a net loss of over 90,000 persons of Puerto Rican origin, while Queens recorded only a very slight increase. Chicago (Cook County, IL), which had the third largest Puerto Rican population in 2005–2007, also saw little growth over the period. In contrast, the largest numeric and percentage increases were in Florida: The Puerto Rican populations in Orange, Hillsborough, and Osceola counties grew between 50% and 78% over the period, and these three counties moved up between 2 and 4 spots in the ranking. Increases between 34% and 40% were recorded in the Connecticut River Valley (Hampden County, MA; Hartford County, CT; and New Haven County, CT), followed by Philadelphia (+28%). Growth was comparatively slower in South Florida, with Broward and Miami-Dade counties recording increases between 15% and 24%; both counties dropped in the ranking.

**Table 4. The Top 15 Counties for Puerto Rican Residents in the United States**

County	Population		Rank			Population Change	
	2005–07	2014–16	2005–07	2014–16	Change	Percentage	Numeric

## Migration Flows from Puerto Rico vs. from Other States

Inflows from Puerto Rico account for only part of the growth of the Puerto Rican population in Florida and other states. Puerto Ricans also move between states, and the population changes through natural increase<sup>[1]</sup> as well. Figure 4 compares the annual inflows from Puerto Rico to Florida to the migration flows of Puerto Ricans moving from other states to Florida during 2005–2016<sup>[2]</sup>. Interestingly, in all years but 2014 and 2015, there were more Puerto Ricans moving from other states to Florida than moving from the island itself. However, migration from Puerto Rico has increased over the period while the migration of Puerto Ricans from other states has been relatively flat. Furthermore, migration flows of Puerto Ricans from Florida to other states also exceeded flows from Florida to Puerto Rico over that period, making the net exchange more balanced (data not shown).

**Figure 4. Annual Inflows of Puerto Ricans to Florida, Puerto Rico vs. Other States, 2005–2016**

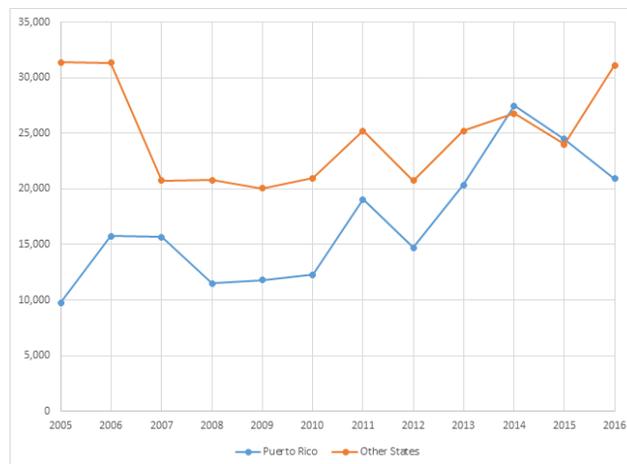

Table 5 displays Florida’s cumulative in-, out-, and net migration flows of Puerto Ricans with the nine states that recorded the largest inflows from Puerto Rico from 2005 to 2016; also shown are the total exchanges with all other states. Over the twelve year period, about 300,000 Puerto Ricans moved from other states to Florida, about 200,000 moved from Florida to other states, resulting in a net gain of about 100,000 Puerto Rican residents. The most lopsided exchanges were with New York and New

Jersey; inflows of Puerto Ricans from these two states to Florida exceeded outflows by about 150% and 235%, respectively. Over the period, about 53,400 more Puerto Ricans moved from New York to Florida than moved in the other direction; other sizable net gains were recorded with New Jersey (+19,300) and Pennsylvania (+11,000). Florida had positive net migration flows with only four of these nine states, as more Puerto Ricans moved from Florida to Texas, Massachusetts, Ohio, Georgia, and California than vice versa. However, except for Texas (-5,300), Florida's net migration losses to these states were quite small.

**Table 5. In-, Out-, and Net Migration of Puerto Ricans between Florida and Other States, 2005–2016**

State	In	Out	Net
New York	88,495	35,069	53,426
Pennsylvania	25,622	14,658	10,964
Texas	12,395	17,718	-5,323
Massachusetts	11,470	11,931	-461
New Jersey	27,455	8,184	19,271
Connecticut	17,594	12,365	5,229
Ohio	3,810	4,228	-418
Georgia	11,743	11,871	-128
California	7,661	8,559	-898
All Other States	298,380	198,968	99,412

### The Impact of Hurricane Maria

The Puerto Rican population in Florida has grown substantially since 2000, especially in Central Florida. The devastation brought about by Hurricane Maria that struck Puerto Rico and the U.S. Virgin Islands in late September of 2017 has raised questions about the demographic impacts on Florida. Since early October, large numbers of residents have been reported leaving Puerto Rico and moving to the U.S. mainland, with Florida being a prime destination. Data on actual flows, however, are still quite sparse, and estimates of the overall size of the flow – both current and for the near future – vary widely. Flight arrival data provide some information, but have historically overstated actual migration flows by wide margins. This is because most air passengers are not

migrants, but tourists, people traveling for business, those visiting family and friends, etc. It is likely that the proportion of migrants from Puerto Rico among air arrivals has been much higher after Hurricane Maria than was true in the past, but we don't yet know by how much.

The most recent Demographic Estimating Conference held December 5, 2017, in Tallahassee, FL, estimated about 53,000 Puerto Ricans and U.S. Virgin Islanders moving to Florida permanently in response to the impacts of Hurricane Maria.<sup>[3]</sup> This estimate was based on counts of Puerto Ricans that have visited Multi-Agency Resource Centers at Orlando International Airport, Miami International Airport, and the Port of Miami through the end of November 2017; flight arrivals and school enrollment data were also considered when making this estimate. It is a reasonable estimate, given the available information at the time, but the eventual number could turn out quite differently. To us, this estimate seems somewhat conservative; we note, however, that some of the higher estimates that have circulated in the news appear to be highly speculative given the available data. This is a good reminder that estimates, like the ACS PUMS data used in this article, include margins of error. However, they are still valuable when done with care, for they do provide information. While we don't yet know how many Puerto Ricans will ultimately decide to leave the island as a response to Hurricane Maria, a not inconsequential demographic impact on Florida seems likely, especially for the greater Orlando area.

# How do Firing Costs Affect Worker Flows in a World with Adverse Selection?\*

Adriana D. Kugler<sup>†</sup> and Gilles Saint-Paul<sup>‡</sup>

May 10, 2002

---

\*A previous version of this paper circulated under the name “Hiring and Firing Costs, Adverse Selection, and Long-term Unemployment.” We are especially grateful to George Akerlof, Josh Angrist, David Autor, Dan Hamermesh, an anonymous referee and the editor of this Journal for very useful comments. We would also like to thank Fernando Alvarez, Giuseppe Bertola, Hugo Hopenhayn, Jennifer Hunt, David Levine, Paul Oyer, Chris Pissarides and François Langot and Omar Licandro, our discussants at the First Macroeconomics Workshop in Toulouse, as well as seminar participants at the first SOLE/EALE Conference in Milan, the CEPR Macro Workshop in Tarragona, the EEEG Annual Conference in Southampton, University Carlos III, University of CEMA, CERGE-EI at Charles University, University College London, FEDEA, IIES, University of Maryland, University Pompeu Fabra, University of Southampton, University Torcuato Di Tella, and IFAW of Uppsala University. We also thank David Autor and Lynn Karoly for providing us with information on the adoption of wrongful-termination doctrines in the U.S.; Jonah Gelbach for providing us with state-level data on welfare benefits, and the Bureau of Labor Statistics for allowing us to use the NLSY’s Geocode file under their confidentiality agreement. Finally, we thank Rubén Segura for help with the extraction of the data. We acknowledge financial support for this project from Foundation BBV and from the Spanish Ministry of Education through CICYT grant No. SEC 98-0301.

## Abstract

This paper provides a theoretical and empirical analysis of a firing costs model with adverse selection. In a heterogeneous world, firms decide who to fire, so low-quality workers are more likely to be dismissed. Our theory suggests that as firing costs increase, firms may increasingly prefer to hire out of the pool of the employed, since the employed are less likely to be lemons. Estimates of re-employment and job-transition probabilities from the NLSY support this prediction. Unjust-dismissal provisions in U.S. states reduce the re-employment probabilities of unemployed workers but have little effect on job-transition rates for the employed. Consistent with a lemons story, the relative effects of unjust-dismissal provisions on the unemployed are generally smaller for union workers, who are subject to layoff-by-seniority rules, and for those who lost their previous jobs due the end of a contract.

# 1 Introduction

Job security regulations are widely believed to reduce firing and hiring. Reduced dismissal rates benefit employed workers, but reduced hiring rates hurt both the unemployed and those employed workers who would like to change jobs. The purpose of this paper is to present and test a theory which suggests that the reduction in hiring caused by firing costs can affect different groups of workers very differently. We show that the reduction in hiring is likely to be more severe for the unemployed than the employed. In a world with adverse selection, firing costs not only lengthen jobless-spells, they may also redistribute new employment opportunities from unemployed to employed workers.

The principal theoretical innovation in our paper is the introduction of adverse selection in a model of firing costs. A standard result in theoretical discussions of firing costs is that hiring and firing rates both fall when workers are protected (see, e.g., Bentolila and Bertola (1990) and Hopenhayn and Rogerson (1993)). Re-employment probabilities in models of adverse selection vary according to the type of separation (Gibbons and Katz (1991)). Our setup combines these features: worker quality is imperfectly observed, so firms must contend with the possibility of hiring a ‘lemon’ in addition to the possible expense of dismissal. When faced with an adverse shock, firms prefer dismissing bad workers who generate lower profits. As a result, in equilibrium, employed workers are more productive than the unemployed. Thus, firms concerned about firing costs will generally find it worthwhile to recruit new workers primarily from the pool of those already employed.

The central theoretical prediction of our model is that an increase in firing costs typically increases discrimination against unemployed job seekers. To test this model, we look at the effect of state unjust-dismissal provisions on the re-employment and job-transition probabilities of unemployed and employed workers using the NLSY. These data are useful for this purpose for three reasons. First, the NLSY allows us to identify job-to-job transitions. Second, we can identify employed and unemployed job seekers. Finally, the NLSY’s Geocode file allows us to identify workers covered by unjust-dismissal provisions.

Our results show reduced re-employment probabilities for the unemployed but not for employed workers over the 1980’s in states that introduced unjust-dismissal provisions. The results are unchanged when controlling for state and time effects, for time-specific and state-specific effects on the unem-

ployed, for interactions between region and time effects, for unemployment benefit receipt, for differential welfare benefits across states, and for differential effects of other variables on unemployed and employed workers. Finally, we check if the relative effect on the unemployed is greater for nonunionized than unionized workers, since unionized jobs are covered by layoff-by-seniority rules, and for dismissed workers than for workers who are unemployed because of the end of a contract. As the lemons story suggests, our empirical findings generally confirm greater effects on nonunionized than unionized workers and on dismissed workers than on end-of-contract workers.

As indicated above, our paper relates to the literatures on adverse selection and firing costs. We extend the influential work on adverse selection of Gibbons and Katz (1991) by including firing costs. More recent asymmetric information models also appear in papers by Montgomery (1999), Canziani and Petrongolo (2001), and Strand (2000). In contrast to our paper, these papers only consider re-employment transitions for the unemployed and not for employed workers.

This paper also relates to the extensive literature that examines the link between firing costs and labor market performance. In contrast to firing costs models without adverse selection, our model predicts a shift in hiring from unemployed to employed workers. Moreover, our work relates to the extensive empirical literature on the impact of firing costs using macro- and micro-data.<sup>1</sup> Our paper shares the methodology with papers using micro-data and the state variation in unjust-dismissal provisions exploited by Autor (2000), Dertouzos and Karoly (1992), Hamermesh (1993), and Miles (2000). Finally, we contribute to the literature contrasting job search outcomes for employed and unemployed workers (e.g., Holzer,1988; Blau and Robbins,1990).

The paper is organized as follows. Section 2 presents and solves the matching model with asymmetric information and on-the-job search. Section 3 extends this model to allow for endogenous meeting rates. In Section 4, we describe the data and present estimates of the effect of dismissal costs on re-employment and job-transition probabilities of unemployed and employed workers. We conclude in Section 5.

---

<sup>1</sup>Studies using aggregate data include: Lazear (1990), Bertola (1990), and Di Tella and McCulloch (1999) among others. There are also a handful of studies examining the impact of firing costs using microdata.

## 2 The Model

### 2.1 Description of the Model

The theoretical framework is based on Mortensen and Pissarides (1994), where we simplify some aspects to preserve tractability but introduce dismissal costs, on-the-job search and adverse selection to capture the phenomena of interest. We show that in contrast to a world without adverse selection, firing costs not only reduce hiring and firing but they could also shift hiring from unemployed to employed workers.

The total labor force is split between two types of workers, ‘good’ and ‘bad’. The proportion of ‘good’ workers is denoted by  $z$ , where the total labor force is normalized to 1. Prior to hiring, firms do not observe the quality of applicants nor their past labor history. They only observe the applicant’s current employment status. Immediately after hiring, however, firms observe the productivity of the worker.<sup>2</sup>

Firms freely enter the market by creating vacant positions. Once the position is created, firms face a cost  $C$  of holding a vacancy. Because of free entry, the value of a vacancy must always be equal to 0 in equilibrium. A job seeker meets a vacant job with probability  $a$  per unit of time, which we take to be exogenous in this section but endogenize in the following section. When meeting a worker, a firm decides whether to hire a worker or not depending on his labor market status. Below, we only consider the case where employed job seekers are hired for sure, which must hold in any equilibrium of interest.<sup>3</sup>

Once a position is filled, production takes place. The firm’s output per unit of time is  $m + \eta$ , where  $m$  is a match-specific component and  $\eta$  is worker-specific. We assume  $\eta = \eta_H$  for good workers and  $\eta = \eta_L < \eta_H$  for bad workers. When the match is initially formed the match-specific component is equal to  $\bar{m}$ , but with probability  $\gamma$  per unit of time the firm is hit by a

---

<sup>2</sup>This assumption is made for simplicity, as it reduces the number of individual states one has to keep track of. One could specify a learning process about the worker’s productivity (as in Jovanovic, 1979), but since we are not dealing with learning aspects we keep this part of the model as simple as possible.

<sup>3</sup>As it will be clear below, the pool of employed job seekers is of higher quality than that of unemployed job seekers, thus generating higher net expected profits. If firms did not hire employed applicants with probability one, then these profits would be negative or zero, implying strictly negative net expected profits out of unemployed applicants. The exit rate from unemployment would then be zero, so that the whole workforce would be unemployed in equilibrium.

shock that changes the productivity of the match. Every time such a shock occurs, the new productivity is drawn from a distribution  $G(m)$  over the interval  $[\underline{m}, \bar{m}]$ .

Wages are assumed to be equal to a base wage,  $\bar{w}$ , plus a constant fraction,  $\varphi$ , of output with worker productivity,  $\eta$ , and match productivity,  $m$ :

$$w(m, \eta) = \varphi(m + \eta) + (1 - \varphi)\bar{w}.$$

This assumption implies that firms make higher profits out of good workers than out of bad ones, which is central to our results.<sup>4</sup>

Production takes place until either the firm closes the position or the worker quits. Firms pay a tax  $F$  when dismissing a worker, which is paid to a third party. We specify firing costs as a tax because, as discussed below, a substantial fraction of firing costs go to third parties such as lawyers, insurers, and the government. In contrast, the firm does not have to pay  $F$  when the worker quits. The quit rate is endogenous and given by the probability of engaging in on-the-job search times the instantaneous probability of receiving an offer,  $a$ . Workers face a flow search cost,  $c$ , from searching on-the-job, but the benefit of searching is that they move to a match with the highest possible level of productivity. Whether the firm dismisses or the worker quits, the position is destroyed and the firm's value drops to zero.

## 2.2 Equilibrium

### 2.2.1 On-the-job Search

We first solve for on-the-job search, which is obtained by comparing the worker's value of being employed while searching and not searching. Let  $E(m, \eta, NS)$  be the value of being employed while not searching for an employed worker of productivity  $\eta$  and match-specific productivity  $m$ . The value of the employed worker who does not search is given by the following Bellman equation,

---

<sup>4</sup>While this holds in a wide variety of models of wage formation (except for the perfectly competitive case, which equates wages to marginal product), the extent to which the results are affected by other assumptions about wage determination is left for future work.

$$\begin{aligned}
rE(m, \eta, NS) &= \varphi(m_{\underline{z}} + \eta) + (1 - \varphi)\bar{w} \\
&\quad + \gamma \int_{m_c}^{\bar{m}} E(m, \eta) g(m) dm + G(m_c(\eta))U(\eta) \\
&\quad - E(m, \eta, NS)], \tag{1}
\end{aligned}$$

where  $U(\eta)$  is the value of an unemployed and  $m_c$  is the critical value of the match-specific productivity that triggers a dismissal, so the last term is the expected capital gain or loss from being hit by a shock. Similarly, the value of an employed job seeker is given by the following Bellman equation,

$$\begin{aligned}
rE(m, \eta, S) &= \varphi(m_{\underline{z}} + \eta) + (1 - \varphi)\bar{w} - c + a [E(\bar{m}, \eta) - E(m, \eta, S)] \\
&\quad + \gamma \int_{m_c}^{\bar{m}} E(m, \eta) g(m) dm + G(m_c(\eta))U(\eta) \\
&\quad - E(m, \eta, S)], \tag{2}
\end{aligned}$$

where the fourth term represents the expected capital gain from quitting into a new job.

Search on-the-job for an employed with match-specific productivity,  $m$ , takes place if  $E(m, \eta, S) \geq E(m, \eta, NS)$ . Since the cost of search is constant and the benefit from searching is that the person moves from the current match to the highest possible match-specific productivity, then the gains from searching on-the-job increase as the current match level decreases. This means that on-the-job search is given up at the unique value,  $\bar{\theta}$ , below which there is always on-the-job search, and which satisfies the condition,

$$E(\bar{\theta}, \eta, S) = E(\bar{\theta}, \eta, NS).$$

Substituting (1) and (2) into the above condition, we can solve for  $\bar{\theta}$  to obtain,

$$\bar{\theta} = \bar{m} - \frac{(r + \gamma)c}{\varphi a},$$

which means that search behavior is independent of worker type. Since the case of interest is given by the case when some workers engage in search, we limit ourselves to the case when the search threshold exceeds the dismissal threshold, i.e.,  $\bar{\theta} > m_c(\eta)$ , for one or both type of workers.<sup>5</sup>

---

<sup>5</sup>Sufficient conditions for the search thresholds to exceed the dismissal thresholds are given in footnote 7.

### 2.2.2 Firing and Hiring Decisions

Given that the residual value of firing the worker is zero, the firm fires the worker if  $J(m, \eta) < -F$ . The value of a job filled with an employed job seeker of productivity  $\eta$  and match-specific productivity  $m \leq \bar{m}$ ,  $J(m, \eta)$ , is given by the following Bellman equation,

$$rJ(m, \eta) = (1 - \varphi)(m + \eta - \bar{w}) - aJ(m, \eta) + \gamma \int_{m_c}^{\bar{m}} J(m, \eta)g(m)dm - G(m_c(\eta))F - J(m, \eta).$$

The second term in the RHS is the expected capital loss experienced by the firm if the worker quits, which conditional on on-the-job search happens with instantaneous probability  $a$ , and the last term is the expected capital gain or loss associated with a productivity shock. Solving for  $J(m, \eta)$  we obtain,

$$J(m, \eta) = \frac{\gamma \mathcal{J}(\eta) + (1 - \varphi)(m + \eta - \bar{w})}{(r + \gamma + a)}, \quad (3)$$

where  $\mathcal{J}(\eta) = \int_{m_c}^{\bar{m}} J(m, \eta)g(m)dm - G(m_c(\eta))F$  is the average value of the match to the firm over the current value of the shock. Similarly, the value of a job filled with an employed worker who does not search, i.e.,  $m > \bar{m}$ , is,

$$J(m, \eta) = \frac{\gamma \mathcal{J}(\eta) + (1 - \varphi)(m + \eta - \bar{w})}{(r + \gamma)}.$$

Since we consider the case in which some workers search before reaching the dismissal threshold, i.e.,  $m_c(\eta) \leq \bar{m}$ , and the dismissal threshold is given by  $J(m_c(\eta), \eta) = -F$ , we obtain the following solution for the dismissal threshold,

$$m_c(\eta) = \frac{-F(r + \gamma + a) - (1 - \varphi)\eta + (1 - \varphi)\bar{w} - \gamma \mathcal{J}(\eta)}{(1 - \varphi)}, \quad (4)$$

which defines a relationship between  $m_c(\eta)$  and  $\mathcal{J}(\eta)$ .<sup>6</sup> Substituting (3) and

---

<sup>6</sup>Without on-the-job search, this relationship is given by,

$$m_c(\eta) = \frac{-F(r + \gamma) - (1 - \varphi)\eta + (1 - \varphi)\bar{w} - \gamma \mathcal{J}(\eta)}{(1 - \varphi)},$$

(4) into  $\mathcal{J}(\eta)$  provides the other relationship between these two unknowns,

$$\mathcal{J}(\eta) = \frac{\int_{\bar{m}}^{\infty} \frac{(1-\varphi)(m+\eta-\bar{w})}{(r+\gamma)} g(m) dm + \int_{m_c}^{\infty} \frac{(1-\varphi)(m+\eta-\bar{w})}{(r+\gamma+a)} g(m) dm - FG(m_c(\eta))}{1 - \frac{\gamma}{(r+\gamma)} [G(\bar{m}) - G(\bar{w})] - \frac{\gamma}{(r+\gamma+a)} [G(\bar{w}) - G(m_c(\eta))]},$$

and substituting this equation into (4) determines  $m_c(\eta)$  uniquely.

Furthermore,  $m_c$  is falling with  $\eta$ , falling with  $F$ , and increasing with  $\bar{w}$ . This means that  $m_c(\eta_L) > m_c(\eta_H)$ , so that we may have two cases with on-the-job search: (a) only some workers search, i.e.,  $m_c(\eta_L) > \bar{w} \geq m_c(\eta_H)$ , in which case only good workers search, or (b) both types of workers search, i.e.,  $\bar{w} \geq m_c(\eta_L) > m_c(\eta_H)$ . We consider the second case which is the least restrictive one, although our results below are strengthened under the first case.<sup>7</sup> Moreover, the dismissal threshold of good workers is more responsive to changes in  $F$  and  $\bar{w}$  than the dismissal threshold of bad workers. Consequently,  $\frac{dm_c(\eta_L)}{dF} < \frac{dm_c(\eta_H)}{dF}$  and  $\frac{dm_c(\eta_L)}{d\bar{w}} < \frac{dm_c(\eta_H)}{d\bar{w}}$ , which is due to a discount effect since good workers are less likely to be fired (see the Appendix for proof).

We now compute the hiring decision of a firm faced with an applicant. The quality of the applicant is unobservable, but his status is observable and provides a signal to the firm. Let  $z_e$ , respectively  $z_u$ , be the proportion of good workers among employed, respectively unemployed, job seekers. Then,

indicating that on-the-job search lowers the dismissal threshold. As in Saint-Paul (1995), firms faced with firing costs may prefer to use attrition and wait until workers quit rather than dismiss at a cost,  $F$ .

<sup>7</sup>The condition for both types of workers to engage in on-the-job search before reaching the dismissal threshold is given by,

$$\bar{m} > \frac{-F(r+\gamma+a) - (1-\varphi)\eta + (1-\varphi)\bar{w} - \gamma\mathcal{J}(\eta)}{(1-\varphi)} + \frac{(r+\gamma)c}{\varphi a}.$$

A sufficient condition for this to hold is,

$$\frac{(r+\gamma)c}{\varphi a} \leq \bar{m} + \frac{F(r+2\gamma)}{(1-\varphi)} + \eta_L - \bar{w}.$$

Similarly, a sufficient condition for good workers to engage in on-the-job search is,

$$\frac{(r+\gamma)c}{\varphi a} \leq \bar{m} + \frac{F(r+2\gamma)}{(1-\varphi)} + \eta_H - \bar{w}.$$

the expected present discounted values associated with hiring an employed and an unemployed applicant are,

$$\Pi_e = z_e J(\bar{m}, \eta_H) + (1 - z_e) J(\bar{m}, \eta_L), \quad (5)$$

$$\Pi_u = z_u J(\bar{m}, \eta_H) + (1 - z_u) J(\bar{m}, \eta_L). \quad (6)$$

Firms prefer to hire an employed applicant rather than an unemployed one, i.e.,  $\Pi_e > \Pi_u$ , since good workers are dismissed less often than bad ones and, thus,  $z_e > z_u$ , and firms make more profits out of good workers,  $J(\bar{m}, \eta_H) > J(\bar{m}, \eta_L)$ .

The firm hires the worker if  $\Pi_i > 0$ , it does not hire if  $\Pi_i < 0$ , and it is indifferent if  $\Pi_i = 0$ . Letting  $p_u$  be the probability that an unemployed worker is hired, then the hiring behavior is represented in the  $(p_u, z_u)$  plane by the EB locus in Figure 1. If the economy is above the horizontal PP line, then  $\Pi_u > 0$ . In this case, all unemployed and employed applicants are hired. If the economy lies on PP, then  $\Pi_e > \Pi_u = 0$ .<sup>8</sup> In this case, all employed applicants are hired, while unemployed applicants are only hired with probability  $p_u$  and, thus, there is discrimination in hiring against the unemployed. The lower hiring rate of the unemployed relative to employed workers reflects statistical discrimination, since firms use employment status to predict productivity. If the economy lies on PP, the EB locus shifts upwards whenever one of the labor cost parameters,  $F$  or  $\bar{w}$ , increases. This is because any parameter change that reduces profits must be offset by an increase in the quality of unemployed applicants. Otherwise, the incentive to hire them would disappear (see Appendix for proof).

### 2.2.3 Steady State Analysis

We complete the joint determination of  $p_u$  and  $z_u$  by deriving a steady state relationship between the two. In steady state, inflows into unemployment must be equal to outflows for each group of workers. Letting  $u$  be the unemployment rate, then:

$$\gamma G_H(z - uz_u) = ap_u uz_u, \quad (7)$$

$$\gamma G_L(1 - z - u(1 - z_u)) = ap_u u(1 - z_u), \quad (8)$$

---

<sup>8</sup>We ignore the case where  $\Pi_u < 0$ , as it would imply a zero outflow from unemployment, so that all workers would be unemployed in steady state.

where  $G_i = G(m_c(\eta_i))$ ,  $i = H, L$ , and  $l_H = (z - uz_u)$  is total employment of good workers and  $l_L = (1 - z - u(1 - z_u))$  is total employment of bad workers. Eliminating  $u$  between these two equations allows us to derive the following steady state relationship between  $p_u$  and  $z_u$ ,

$$z_u = z \frac{\gamma + \frac{ap_u}{G_L}}{\gamma + ap_u \left( \frac{1-z}{G_H} + \frac{z}{G_L} \right)}. \quad (9)$$

This equation determines the steady state (S-S) locus, which provides a condition between  $p_u$  and  $z_u$  that keeps the composition of employment and unemployment time invariant. The S-S locus is downward sloping, because a lower  $p_u$ , i.e., a lower exit rate from unemployment, makes the steady state composition of the unemployment pool more similar to its source population - i.e., the employed, who are of better quality.

The equilibrium is determined by the point where the S-S locus crosses the EB locus. Hiring discrimination against the unemployed (i.e.,  $p_u < 1$ ) arises whenever the S-S locus cuts the EB locus along its horizontal portion PP (see Figure 2a). The job finding rates of employed and unemployed job seekers are the same if the S-S locus cuts the EB locus from above (see Figure 2b).

The total number of employed job seekers is given by the fraction of good workers who search among all good workers plus the fraction of bad workers who search among all bad workers,

$$l_s = l_H \frac{\tilde{A} \mathcal{G} - G_H}{1 - G_H} + l_L \frac{\tilde{A} \mathcal{G} - G_L}{1 - G_L}.$$

Consequently, using the steady state conditions, the proportion of good workers among employed job seekers is,

$$z_e = \frac{l_H \frac{\mathcal{G} - G_H}{1 - G_H}}{l_H \frac{\mathcal{G} - G_H}{1 - G_H} + l_L \frac{\mathcal{G} - G_L}{1 - G_L}}.$$

### 2.3 Effects of Firing Costs

The comparative statics relationship of interest is the effect of changes in firing costs,  $F$ , on the hiring of the unemployed. We have already seen that the EB locus shifts upwards when  $F$  increases. If the S-S locus did not

move, the increase in firing costs would make firms choosier and would lead to greater discrimination of the unemployed, i.e., a fall in  $p_u$ . However, the S-S locus does move when  $F$  increases because it affects the firing margins  $m_c(\eta_H)$  and  $m_c(\eta_L)$ . Both the inflow into unemployment of good and bad workers are reduced by firing costs. If the latter were reduced more than the former, then the quality of the unemployed would improve. However, if the inflow of bad workers was reduced more than the inflow of good workers, then the quality of the unemployed would worsen. The S-S locus could then move up or down. Proposition 1 shows that, under reasonable conditions about the distribution of the shocks, the S-S locus shifts down so that an increase in  $F$  unambiguously reduces  $p_u$ .

**PROPOSITION 1** - If the distribution  $G$  satisfies the nonincreasing hazard property, i.e.,

$$\frac{g(m)}{G(m)} \text{ is nonincreasing with } m, \quad (10)$$

the S-S locus moves down when firing costs,  $F$ , increase.

Proposition 1 which is proved in the Appendix shows that, given hiring policies, an increase in firing costs decreases the job loss rate more for good than for bad workers and, therefore, worsens the quality of the unemployed. This comes from two effects. First, as shown above, the dismissal threshold is more sensitive for good workers because of lower discounting. Second, if the nonincreasing hazards assumption holds, a given change in the dismissal threshold has a greater relative effect on the number of people being fired the smaller that number.<sup>9</sup> Since fewer good workers are fired, their firing rate falls proportionately more than for bad workers, thus, reducing the average quality of job losers.

Figure 3 illustrates Proposition 1. Higher firing costs exacerbate discrimination in hiring against unemployed workers, both because firms require better unemployed applicants and because under (10) firing costs reduce the quality of job losers.<sup>10</sup> In this model with adverse selection, higher firing

---

<sup>9</sup>Of course, the nonincreasing hazard assumption need not hold, but it holds for a wide range of distributions, including the uniform distribution and any distribution that does not have an accentuated interior mode. Even when property (10) does not hold, we can still establish that, under reasonable conditions, discrimination against the unemployed disappears with low enough firing costs (see Appendix).

<sup>10</sup>In contrast, while an increase in wages also shifts the EB locus up, its effect on the S-S locus goes in the opposite direction of the effect of firing costs when the nonincreasing hazard assumption holds.

costs are likely to reduce job transition probabilities for unemployed but not for employed workers, for whom it is given by the exogenous instantaneous probability of receiving an offer,  $a$ . When  $a$  is made endogenous, as in the next section, the job finding rate of employed job seekers may also fall with  $F$ , but by less than the unemployed's. Furthermore, as shown below, the job-to-job flow may even go up with  $F$  as a greater fraction of the employed engage in on-the-job search.

### 3 Endogenous Meeting Rates

In this section, the meeting rate between firms and workers is now determined by firms' optimal choices about vacancies. In particular, total contacts between searching firms and workers are generated by a matching function,

$$h = m(v, u + l_s),$$

where  $v$  is the number of vacant jobs. Consequently, the arrival rate of offers and the arrival rates of employed and unemployed job seekers are,

$$a = \frac{m(v, u + l_s)}{u + l_s} = m(\theta, 1),$$

$$\lambda_e = \frac{l_s}{u + l_s} \frac{m(v, u + l_s)}{v} = \frac{l_s}{u + l_s} m\left(1, \frac{1}{\theta}\right) = \frac{l_s}{u + l_s} q(a), \quad (11)$$

$$\lambda_u = \frac{u}{u + l_s} \frac{m(v, u + l_s)}{v} = \frac{u}{u + l_s} m\left(1, \frac{1}{\theta}\right) = \frac{u}{u + l_s} q(a), \quad (12)$$

where  $\theta = \frac{v}{u + l_s}$  and  $q(a) = m\left(1, \frac{1}{\theta}\right)$ , with  $q'(a) < 0$ .

The number of vacant jobs is determined by the entry decision of firms, where the value of a vacancy  $V$  satisfies,

$$rV = -C + \lambda_e (\Pi_e - V) + \lambda_u p_u (\Pi_u - V). \quad (13)$$

An equilibrium is a set of endogenous variables such that, in addition to the equilibrium conditions derived in the previous section, the equilibrium condition  $V = 0$  holds. Hence, eliminating  $\lambda_e$  and  $\lambda_u$ , we have one additional endogenous variable,  $a$ , and one additional equilibrium condition.

In equilibrium, free entry implies that  $V = 0$ , and this free entry condition determines the total number of vacancies,  $v$ . Given the equilibrium value

of  $a$ , the arrival rates and the number of vacancies can then be recursively computed using the preceding equations.

The following theorem (see proof in Appendix) tells us that an equilibrium always exists and that, when nontrivial, it is “well behaved.”

**THEOREM -**

(i) Either there exists a zero employment equilibrium such that  $a = 0$  and  $u = 1$ , or

(ii) there exists an equilibrium with  $a > 0$ , which is “stable” in the sense that the value of the firm is locally decreasing in  $a$ .

A sufficient condition for (i) to be ruled out is  $zJ(\bar{m}, \eta_H) + (1 - z)J(\bar{m}, \eta_L) > 0$ , where the  $J$ 's are computed using  $a = 0$ . This means that  $a = 0$  cannot be an equilibrium, since it would then be profitable for an atomistic firm to deviate by hiring an unemployed worker, who would never quit and is good with probability  $z$ . The last part of claim (ii) refers to the case where  $a$  is treated as exogenous, as in the previous section. This means that around the equilibrium value of  $a$ , the value of a vacancy,  $V$ , is negatively related to labor market tightness,  $a$ .

This stability property implies that any parameter shift which reduces the value of the firm given  $a$ , will reduce the equilibrium value of  $a$ . This is typically true of an increase in the firm's labor costs,  $F$ ,  $\bar{w}$ , and  $\varphi$ . Since it is difficult to say more analytically, we turn to numerical simulations.

The simulation results, reported in Table 1, suggest the following conclusions:

1. For low values of  $F$ , low quality workers do not engage in on-the-job search because the threshold value of  $m$  at which they are fired is higher than the threshold value of  $m$  below which they search. In this zone, an increase in  $F$  increases  $a$ . In this zone,  $p_u = 1$ , and  $z_e = 1$ , as all employed job seekers are of good quality. The economy then moves to a zone where both types of workers search on the job as  $F$  increases. In this zone,  $p_u$  and  $a$  fall monotonically with  $F$ , and one eventually reaches a zone where  $p_u < 1$ .

2. For  $F > 0.1$ , the unemployment-to-job flow, which is equal to  $ap_u$ , falls with  $F$ , and its fall accelerates in the zone where  $p_u < 1$ , where both  $a$  and  $p_u$  fall in response to  $F$ .

3. The job-to-job flow is hump-shaped, as a result of two conflicting effects. First, an increase in firing costs widens the distribution of productivity levels among employed workers, thus increasing the proportion of employed workers engaged in on-the-job search. Second, it reduces  $a$ , thus reducing the job finding rate of all job seekers. Our simulations suggest that at low

firing costs the first effect dominates, while the second does at high firing costs.

4. The job loss rate monotonically decreases with  $F$ , as expected.

5. In the zone where  $p_u = 1$ , the quality of unemployed job seekers falls with  $F$  for  $F > 0.2$ . This is because under the conditions of Proposition 1 the inflow into unemployment is more responsive to  $F$  for good than for bad workers. In the zone where  $p_u < 1$ , the quality of the unemployed goes up with  $F$ , due to the mechanisms already explained in the previous section. The quality of employed job seekers follows a similar U-shaped pattern.

6. The unemployment rate,  $u$ , falls with  $F$  in the zone where  $p_u = 1$ , implying that the effect of a lower job loss rate is stronger than that of a lower job finding rate. The unemployment rate goes up in the zone where  $p_u < 1$ , where the job finding rate falls much more rapidly in response to  $F$  due to the downward adjustment of the discrimination parameter  $p_u$ .

Similar to the results with exogenous meeting rates, these results show that as firing costs rise, the job finding rates of the unemployed decrease relative to those of the employed.

## 4 The Impact of Dismissal Costs on Accession Rates

This section provides evidence on the impact of unjust-dismissal provisions in the U.S. on the re-employment and job-transition probabilities of unemployed and employed workers. Before turning to the data and the empirical analysis, we provide a description of the changes in firing costs in U.S. states over the 1970's and 1980's.<sup>11</sup>

### 4.1 Exceptions to Employment-at-will

Until the 1959 ruling by California's Appellate Court imposing restrictions on dismissals, the common-law rule known as the employment-at-will doctrine applied in all U.S. states. The employment-at-will doctrine determined that employers could "discharge or retain employees at-will for good cause or for no cause, or even for bad cause without thereby being guilty of an unlawful

---

<sup>11</sup>Much of the description on the evolution of the legal environment that follows is based on Autor (2000), Dertouzos and Karoly (1992), and Miles (2000).

act per se.”<sup>12</sup> During the 1980’s the U.S. experienced a sharp and probably unanticipated rise in the recognition of exceptions to employment-at-will, leaving only four out of the fifty-one states as strictly employment-at-will states by the 1990’s.

The exceptions to at-will employment adopted during the last few decades in the U.S. can be grouped into three main categories: the implied contract doctrine, the public policy doctrine, and the covenant of good faith and fair dealing. The implied contract doctrine establishes that the employment relationship may be governed by implied contractual provisions restricting the ability of employers to terminate employees. The courts establish evidence of an implied contract from written and oral statements, employment practices and manuals, employees’s length of service, and the general context of the employment relationship. While only six states had recognized the implied contract doctrine by 1981, by the 1990’s forty two states had introduced exceptions to employment-at-will based on the implied contract rule.

Public policy exceptions bar employers from terminating employees for refusing to commit an act contrary to public policy or for committing an act protected by public policy. The public policy doctrine is usually defined to include only statutes. Only in a few cases, has it been applied more broadly to include regulations, administrative rules, and professional codes of ethics. For this reason, the public policy doctrine appears to be less restrictive to employers than the implied contract exception. The public policy doctrine was first recognized in 1959 by California, but it was only widely accepted by most states during the 1980’s. By the 1990’s, 42 states had recognized the public policy doctrine, but only eight of them in its broader form.

A third less-widely recognized exception is the covenant of good faith and fair dealing, which bars employers from dismissing workers in order to deprive them from earned benefits (e.g., pensions and bonuses). Many legal scholars have considered the covenant of good faith as being potentially the most far reaching of the three doctrines, in that it can imply that dismissal must always be for cause. However, in spite of the early recognition of this doctrine in 1974, only 12 other states had issued similar decisions in support of this exception by the 1990’s.

There is little information on the actual costs imposed by these unjust dismissal exceptions. A study of wrongful discharge cases by Dertouzos et al. (1988) in California, however, reported average compensatory damages

---

<sup>12</sup>Payne v. Western & Atlantic Railroad (1884), Tennessee Supreme Court.

of \$388,500 and average legal fees of \$98,000 in cases where the defense won and \$220,000 in cases where the plaintiff won. The costs going to third parties (i.e., lawyers) suggest the importance of the firing tax component of dismissal costs.

In the empirical analysis that follows, we distinguish among the three types of exceptions. We construct the dismissal legislation variables using the classifications of the doctrines in Autor (2000) and checked the robustness of our results using the classification provided by Dertouzos and Karoly (1992).<sup>13</sup>

## 4.2 Data Description

We use the random sample of 6,111 individuals in the NLSY for the years 1979-84 and 1996. In these years employed workers were asked about their job search activities and, in particular, were asked whether they were looking for another job. This allows us to contrast employed and unemployed job seekers. The unemployed are defined in the usual way as individuals who did not work during the survey week and were looking for work or on layoff. Employed job seekers are defined as those individuals who worked during the survey week and were looking for work. These same definitions were used by Blau and Robbins (1990) and Holzer (1988) in studies of job search by employed and unemployed workers.

The NLSY work history file allows us to track employer-specific data and to correctly identify job-to-job transitions. For multiple job holders, the ‘main job’ was identified as the job in which the worker earned the most during that week. Moreover, since observations are defined by search spells of employed and unemployed workers, an individual worker can contribute more than one observation if, for example, the worker is unemployed during two or more sample years or if the worker is an employed job seeker in one sample year and unemployed in another. We eliminated the following observations from the sample: all observations with a real wage less than one 1979 dollar, workers in the public sector, persons serving in the military, agricultural workers, and the self-employed.<sup>14</sup> In addition, while the youngest person in

---

<sup>13</sup>Since the results using the Dertouzos and Karoly (1992) classification were almost identical to those using the classification provided by Autor (2000), we only present the results based on the latter.

<sup>14</sup>Workers in the public sector and the military are eliminated because we want to concentrate on workers hired by profit-making businesses. Agricultural workers are eliminated

the NLSY enters the sample at 14, we restrict our sample to workers 17 years of age or older. The oldest workers reach age 39 in our sample period.

Most importantly for our purposes, the Geocode file allows to generate the job security provision variables, as it identifies the state of residence of each individual at the time of the interview. The Geocode file contains the unemployment rate in the respondent's county of residence.

### 4.3 Descriptive Statistics

Simple comparisons show that workers covered by unjust-dismissal provisions have higher job-finding rates than uncovered workers. This can be seen in the first row of Table 2, which reports the job-finding probability of workers covered by exceptions to be 0.026 higher than for uncovered workers. As Table 3 shows, this difference comes from the higher job-finding rates of the employed covered by exceptions, but hides the lower job-finding rates of unemployed workers covered by exceptions. Other comparisons by unjust-dismissal status show broadly similar characteristics between the two groups of workers. For example, the overall proportion of searchers unemployed is 41.3% and slightly higher among those covered by exceptions than among those in employment-at-will states, but the difference is not statistically significant.<sup>15</sup>

To illustrate the differential impact of unjust-dismissal provisions on unemployed and employed job seekers, Table 3 presents a set of contrasts in accession rates between unemployed and employed individuals in adopting and non-adopting states. The first panel of Table 3 shows differences in average accession rates for workers in covered states (i.e., adopting states after adoption of the doctrines) and uncovered states (i.e., non-adopting states as well as adopting states before adoption), for unemployed and employed workers. For example, the first and second rows in the first column show that the average job-finding rate of unemployed workers in covered states is 0.503, while the average job-finding rate of unemployed workers in uncovered states is 0.53. The third row presents the difference in average job-finding

---

because these workers are likely to have seasonal contracts and unlikely to be subject to unjust-dismissal doctrines. The self-employed are eliminated because they are not subject to adverse selection problems.

<sup>15</sup>This implies that about 60% of searchers in our sample are employed. Statistics not shown in the table indicate that about 20% of employed workers search, with about equal proportions searching in covered and non-covered states.

rates between covered and uncovered workers. These results show that the average job-finding rate is 0.03 lower for unemployed workers and 0.05 higher for employed workers in adopting compared to non-adopting states. The last row in Panel A contrasts the difference in average job-finding rates between covered and uncovered workers for those employed and unemployed. The results show that the employed-unemployed difference in average job-finding rates increased for workers living in states that introduced unjust-dismissal exceptions relative to the control group living in non-adopting states.

Panels B, C, and D show similar estimates for unemployed and employed workers, where coverage status is defined for the implied contract, public policy, and good faith doctrines separately. The results in the last row of Panels B, C, and D show that the employed-unemployed job-finding difference increased in those states that introduced each of these doctrines compared to those that did not.

#### 4.4 Probit Estimates

To estimate the impact of unjust-dismissal exceptions on the re-employment probabilities of unemployed relative to employed workers while controlling for other variables, we estimate the following reduced-form probit model:

$$\Pr(y_{ijt} = 1|x_{ijt}, u_{ijt-1}) = \Phi(\alpha'x_{ijt} + \tau_t + \theta_j + \delta u_{ijt-1} + \beta_{0t}u_{ijt-1} + \beta_{1j}u_{ijt-1} + \beta_2'd_{jt} + \beta_3'd_{jt} \times u_{ijt-1}),$$

where the dependent variable  $y_{ijt}$  takes the value of one if an unemployed or employed worker was observed searching for a job at time  $t - 1$  and has found a job by the next calendar year and zero if he did not find a job within that calendar year. The vector  $x_{ijt}$  includes a set of individual controls for individual  $i$  living in state  $j$  at time  $t$ . The terms  $\theta_j$  and  $\tau_t$  are state and year effects, and  $u_{ijt-1}$  is an unemployment dummy which takes the value of 1 if the person was unemployed and the value of 0 if the person was employed and searching for another job at time  $t - 1$ . The parameter  $\beta_{0t}$  captures differences in year effects by employment status and  $\beta_{1j}$  captures differences in state effects by employment status. The set of dummies,  $d_{jt}$ , indicate coverage by the three unjust-dismissal exceptions, which take the value of 1 if the individual is observed living in a state  $j$  that has adopted the implied contract, public policy, or good faith exceptions at time  $t$  and zero otherwise.

The vector  $\beta_2$  thus measures the direct impact of unjust-dismissal exceptions on employed workers. Finally, the vector  $\beta_3$  measures the differential impact of unjust-dismissal exceptions on the unemployed relative to employed workers.

Table 4 presents estimates from the probit of the direct impact of unjust-dismissal exceptions on employed workers and their relative impact on the unemployed,  $\beta_2$  and  $\beta_3$ , as well as the impact of unemployment status on job-finding probabilities,  $\delta$ . The first four columns of Table 4 present the results for the probit with basic controls.<sup>16</sup> The coefficient  $\beta_3$  in Column (1) shows that the implied contract exception reduces the job finding probability of unemployed workers by 0.175 relative to employed workers. Columns (2) and (3) show smaller effects for unemployed relative to employed workers covered by the public policy and good faith doctrines, 0.091 and 0.073 respectively. Column (4) shows similar results when all three exceptions are included.<sup>17</sup> These results also indicate that the job-finding probability of unemployed workers is about 0.4 higher than for employed workers.

Columns (5)-(8) in Table 4 show the results of the probits with the basic controls as well as all first-level and second-level main effects: time and state effects, and time-unemployed and state-unemployed interactions. Time effects are included to capture the possibility that the introduction of exceptions may have coincided with other changes that were instead responsible for the low job-finding rates. State effects are included because the exceptions may be capturing the low job-finding rates of workers in those states that introduced exceptions for reasons unrelated to the exceptions. The time-unemployed and state-unemployed interactions are included to control for time-specific and state-specific factors affecting the unemployed but unrelated to the unjust-dismissal doctrines. In addition, these probits include interaction between time and region effects to control for time-varying regional shocks that may affect accession rates. Columns (5) and (6) in Table 4 indicate smaller effects of the implied contract and public policy exceptions on the job-finding probability of the unemployed relative to employed

---

<sup>16</sup>The controls include: age, education, number of children, tenure, wage, non-wage income, local unemployment rate, dummies for race, sex, and marital status, a manufacturing dummy, a union dummy, and a white-collar dummy. The job related variables (i.e., tenure, wage, union, sector, and occupation) for the unemployed refer to their previous job.

<sup>17</sup>The estimates in Columns (1)-(4) are quite precise because these models omit main state and year effects.

workers, after controlling for time, state, time, and time-unemployed, state-unemployed and time-region interaction terms. Column (7), however, shows a larger effect of the good faith exception when all first-level and second-level terms are included, indicating that this exception reduces the job-finding probability of unemployed workers by 0.122. This corresponds to a reduction of about 23% in the unemployed's job-finding probability from 0.516 to 0.394. The results in Column (8), including all exceptions, show that the exceptions together reduced the job-finding probability of the unemployed by 0.161 relative to employed workers.

Columns (9)-(12) in Table 4 present results for the probits including the basic controls, all first- and second-level main effects, and also an unemployment benefit receipt variable. The unemployment benefit variable is included because the lower job-finding probability for the unemployed in states with exceptions may be capturing the higher propensity for the unemployed to claim benefits in these states. Column (9)-(12) show very similar effects of the exceptions after controlling for unemployment benefit receipt.

The results in Table 4 show a negative impact of dismissal costs on the job-finding probabilities of unemployed relative to employed workers. Our results are robust to the inclusion of time and state effects, time-specific and state-specific effects on the unemployed, time-region interactions and unemployment benefit receipt.<sup>18</sup>

Tables 5 and 6 present additional evidence consistent with the lemons story. Following Gibbons and Katz (1991), in Table 5 we examine the impact of dismissal costs on nonunion and union workers. Since firms have less discretion firing workers covered by collective-bargaining agreements, the lemons effect generated by dismissal costs should be smaller for union workers. Columns (1)-(4) in Table 5 show the results for the nonunion sub-

---

<sup>18</sup>To further probe the robustness of the results, we estimate probits which control for the maximum available welfare benefits (including AFDC benefits and food stamps) in a state at each point in time, since during this time period not only did unjust-dismissal legislation change differentially across states but also the generosity of welfare benefits. The results including welfare benefits are similar to those reported in Table 4 and even slightly larger. In addition, we estimate models allowing for differential effects of the basic controls on unemployed and employed workers. The magnitude of the effects is somewhat smaller but remains large and significant. Finally, we estimate analogous linear probability and logit models with and without individual fixed-effects. The resulting individual fixed-effects estimates are less precise but also suggest that the exceptions had large negative effects on the unemployed relative to employed workers.

sample and Columns (5)-(8) for the union sub-sample.<sup>19</sup> Consistent with a lemons story, the estimates suggest that the implied contract and public policy doctrines had larger effects on nonunionized than unionized workers.

Table 6 presents results by reason for separation. It is widely believed that firms use temporary contracts as a way of avoiding dismissal costs and also as a way of screening workers (see, e.g., Autor (2000, 2001)). One may thus expect for workers who have separated due to the end of one of these contracts to be stigmatized by unemployment in the same way dismissed workers are. At the same time, stigma effects should become less important for those under temporary contracts relative to those under permanent contracts as dismissal costs rise. As dismissal costs rise, firms will use more discretion in dismissing those under permanent contracts but not those under temporary contracts. Table 6 shows estimates of models including interactions with a dismissal dummy.<sup>20</sup> These results indicate higher job-finding probabilities of dismissed relative to end-of-contract workers in employment-at-will states, but smaller relative job-finding probabilities for dismissed workers covered by the exceptions.

## 5 Conclusion

The matching model with asymmetric information presented in this paper shows that firing costs are likely to generate hiring discrimination against the unemployed. This is true whether or not meeting rates are endogenous. Estimates using the NLSY indicate increased discrimination in hiring against the unemployed in the U.S. over the 1980's in those states that introduced exceptions to employment-at-will. These results are unchanged by including state and time effects, time-specific and state-specific effects on the unemployed, interactions between region and time effects, unemployment benefit receipt, and welfare benefits. Moreover, consistent with a lemons story, we find that the relative effect of the exceptions on the unemployed is generally

---

<sup>19</sup>There are too few observations in the union/good faith sample to be able to estimate the impact of the good faith doctrine on unionized workers.

<sup>20</sup>In this case, the sub-samples of dismissed and end-of-contract workers are too small for the completely separate analysis to be informative. Since our model does not make predictions about voluntary quitters into unemployment, we exclude them from our sample and consider only dismissed and end-of-contract workers. Effects on voluntary quitters are harder to interpret since this sort of exit may be taken as a signal of weak labor market attachment.

smaller for unionized workers, who are subject to layoff-by-seniority rules, and for those who lost their jobs due to an end-of-contract and, thus, are not subject to dismissal costs.

While our empirical analysis used U.S. data, the results also have implications for European labor markets. Since European countries have high dismissal costs compared to North-America, European firms should discriminate even more against unemployed job seekers. These predictions are consistent with the findings in Bertola and Rogerson (1997) and Boeri (1999), which show much lower flows into and out of unemployment but similar job-to-job flows in the two continents. Our paper suggests that employment protection legislation together with information asymmetries probably play an important role in explaining these differences.

## Appendix

**PROPERTIES OF EQUATION (4)** - The RHS of equation (4) is increasing in the dismissal threshold  $m_c(\eta)$ , so that equation (4) determines  $m_c$  uniquely. Totally differentiating equation (4) with respect to  $\eta$ ,  $\bar{w}$ , and  $F$  we get,

$$\begin{aligned}\frac{dm_c}{d\eta} &= -1 - \frac{\gamma}{(1-\varphi)} \frac{d\mathfrak{P}(\eta)}{d\eta}, \\ \frac{dm_c}{d\bar{w}} &= 1 - \frac{\gamma}{(1-\varphi)} \frac{d\mathfrak{P}(\eta)}{d\bar{w}}, \\ \frac{dm_c}{dF} &= -\frac{(r+\gamma+a)}{(1-\varphi)} - \frac{\gamma}{(1-\varphi)} \frac{d\mathfrak{P}(\eta)}{dF},\end{aligned}$$

and differentiating equation (5) with respect to  $\eta$ ,  $\bar{w}$ , and  $F$  and using the envelope theorem we obtain,

$$\begin{aligned}\frac{d\mathfrak{P}(\eta)}{d\eta} &= \frac{\frac{(1-\varphi)}{(r+\gamma)} (G(\bar{m}) - G(\bar{\theta})) + \frac{(1-\varphi)}{(r+\gamma+a)} (G(\bar{\theta}) - G(m_c))}{1 - \frac{\gamma}{(r+\gamma)} (G(\bar{m}) - G(\bar{\theta})) + \frac{\gamma}{(r+\gamma+a)} (G(\bar{\theta}) - G(m_c))} > 0, \\ \frac{d\mathfrak{P}(\eta)}{d\bar{w}} &= -\frac{d\mathfrak{P}(\eta)}{d\eta} < 0, \\ \frac{d\mathfrak{P}(\eta)}{dF} &= \frac{-G(m_c(\eta))}{1 - \frac{\gamma}{(r+\gamma)} (G(\bar{m}) - G(\bar{\theta})) + \frac{\gamma}{(r+\gamma+a)} (G(\bar{\theta}) - G(m_c))} < 0.\end{aligned}$$

Substituting these into the above equations, we obtain that,  $\frac{dm_c}{d\eta} < 0$ ,  $\frac{dm_c}{d\bar{w}} > 0$ , and  $\frac{dm_c}{dF} < 0$ .

Furthermore, we can see that the dismissal threshold of good workers responds more to changes in labor costs than the dismissal threshold of bad workers. Given that  $\frac{dm_c}{d\eta} < 0$  and, thus,  $m_c(\eta_H) < m_c(\eta_L)$ , then  $0 > \frac{d\mathfrak{P}(\eta_H)}{dF} > \frac{d\mathfrak{P}(\eta_L)}{dF}$  and we get that,

$$0 > \frac{dm_c(\eta_L)}{dF} > \frac{dm_c(\eta_H)}{dF}.$$

Similarly, given that  $m_c(\eta_H) < m_c(\eta_L)$ , then  $0 > \frac{d\mathfrak{P}(\eta_L)}{d\bar{w}} > \frac{d\mathfrak{P}(\eta_H)}{d\bar{w}}$  and,

$$\frac{dm_c(\eta_H)}{d\bar{w}} > \frac{dm_c(\eta_L)}{d\bar{w}} > 0,$$

which proves that there is a greater response of  $m_c(\eta_H)$  than of  $m_c(\eta_L)$  to changes in  $F$  and  $\bar{w}$ .

**PROPERTIES OF EB** -  $\Pi_u$  can be written as a function of  $z_u$  and the exogenous parameters of the model.  $J(\bar{m}, \eta_H)$  and  $J(\bar{m}, \eta_L)$  can be computed using (3) and substituting  $\mathfrak{p}(\eta)$ , which only depends on  $m_c(\eta)$  and on exogenous parameters. Given that  $m_c(\eta)$  is a sole function of such parameters,  $\Pi_u$  can be written as a function of  $z_u$  and exogenous parameters,

$$\begin{aligned} 0 &= \Pi_u = z_u J(\bar{m}, \eta_H) + (1 - z_u) J(\bar{m}, \eta_L) \\ &= z_u \left[ \frac{(1 - \varphi)(\bar{m} + \eta_H - \bar{w})}{(r + \gamma + a)} \right. \\ &\quad \left. + \frac{\gamma \int_{\bar{m}}^{\infty} \frac{(1 - \varphi)(m + \eta_H - \bar{w})}{(r + \gamma)} g(m) dm + \int_{m_c(\eta_H)}^{\infty} \frac{(1 - \varphi)(m + \eta_H - \bar{w})}{(r + \gamma + a)} g(m) dm - FG(m_c(\eta_H))}{(r + \gamma + a) \left[ 1 - \frac{\gamma}{(r + \gamma)} [G(\bar{m}) - G(m_c(\eta_H))] - \frac{\gamma}{(r + \gamma + a)} [G(m_c(\eta_H)) - G(m_c(\eta_H))] \right]} \right] \\ &\quad + (1 - z_u) \left[ \frac{(1 - \varphi)(\bar{m} + \eta_L - \bar{w})}{(r + \gamma + a)} \right. \\ &\quad \left. + \frac{\gamma \int_{\bar{m}}^{\infty} \frac{(1 - \varphi)(m + \eta_L - \bar{w})}{(r + \gamma)} g(m) dm + \int_{m_c(\eta_L)}^{\infty} \frac{(1 - \varphi)(m + \eta_L - \bar{w})}{(r + \gamma + a)} g(m) dm - FG(m_c(\eta_L))}{(r + \gamma + a) \left[ 1 - \frac{\gamma}{(r + \gamma)} [G(\bar{m}) - G(m_c(\eta_L))] - \frac{\gamma}{(r + \gamma + a)} [G(m_c(\eta_L)) - G(m_c(\eta_L))] \right]} \right]. \end{aligned} \tag{14}$$

Furthermore,  $\frac{\partial \Pi_u}{\partial z_u} = J(\bar{m}, \eta_H) - J(\bar{m}, \eta_L) > 0$ . Therefore, there exists a unique value of  $\bar{z}_u$  such that the condition  $\Pi_u = 0$  is satisfied. This defines a horizontal line PP, which delimits the plane between a region where  $\Pi_u > 0$ , in which case  $p_u = 1$ , and a region where  $\Pi_u < 0$ , in which case  $p_u = 0$ . This establishes the shape of the EB locus.

Next, totally differentiating (14), we obtain that the derivatives of the second and fourth terms in the brackets with respect to  $m_c(\eta)$  are zero. Thus, the effects of  $F$  and  $\bar{w}$  on  $z_u$  reduce to the direct effects of these parameters on profits,

$$\frac{dz_u}{dF} = \frac{\gamma \frac{z_u G(m_c(\eta_H))}{D_H} + \frac{(1 - z_u) G(m_c(\eta_L))}{D_L}}{(r + \gamma + a) (J(\bar{m}, \eta_H) - J(\bar{m}, \eta_L))} > 0,$$

$$\frac{dz_u}{d\bar{w}} = \frac{(1-\varphi) \frac{z_u}{D_H} + \frac{(1-z_u)}{D_L}}{(r+\gamma+a)(J(\bar{m}, \eta_H) - J(\bar{m}, \eta_L))} > 0,$$

where  $D_H = 1 - \frac{\gamma}{(r+\gamma)} [G(\bar{m}) - G(\bar{\theta})] - \frac{\gamma}{(r+\gamma+a)} [G(\bar{\theta}) - G(m_c(\eta_H))]$  and  $D_L = 1 - \frac{\gamma}{(r+\gamma)} [G(\bar{m}) - G(\bar{\theta})] - \frac{\gamma}{(r+\gamma+a)} [G(\bar{\theta}) - G(m_c(\eta_L))]$ .

**PROOF THAT S-S IS DOWNWARD SLOPING** - Differentiating equation (9) with respect to  $p_u$ , shows that the sign of the slope is equal to the sign of the following expression,

$$\frac{dz_u}{dp_u} \propto \gamma a z (1-z) \left( \frac{1}{G_L} - \frac{1}{G_H} \right),$$

which is negative since  $G_H < G_L$ . Q.E.D.

**PROOF OF PROPOSITION 1** - Differentiating equation (9), while holding  $p_u$  constant, the direction of the move of the S-S locus in response to an increase in  $F$  is of the same sign as,

$$\begin{aligned} \frac{dz_u}{dF} \propto & -\gamma \frac{g_L}{(G_L)^2} \frac{dm(\eta_L)}{dF} - \frac{g_H}{(G_H)^2} \frac{dm(\eta_H)}{dF} \\ & - \frac{ap_u}{G_H G_L} \frac{g_L}{G_L} \frac{dm(\eta_L)}{dF} - \frac{g_H}{G_H} \frac{dm(\eta_H)}{dF}, \end{aligned}$$

We know from the properties of equation (4) that  $0 > \frac{dm_c(\eta_L)}{dF} > \frac{dm_c(\eta_H)}{dF}$ . Thus, given that  $G_L > G_H$  and the nonincreasing hazard assumption,  $\frac{dz_u}{dF}$  is clearly negative. Q.E.D.

**PROOF THAT IF  $F$  IS LOW ENOUGH,  $p_u = 1$**  - Assume  $\bar{m} + \eta_H > \bar{w}$ . This means that it is at least profitable for firms to employ good workers in the best possible state. At  $F = 0$ , one has  $J(\bar{m}, \eta_H) > -F = 0$  and  $J(\bar{m}, \eta_L) \geq -F = 0$ , implying  $\Pi_u > 0$  for all  $z_u$ . By continuity, this property holds in the neighborhood of  $\bar{F} = 0$ . Q.E.D.

**PROOF OF THEOREM** - Equation (13) is equivalent to

$$C = \lambda_e \Pi_e + \lambda_u p_u \Pi_u. \quad (15)$$

The equations of Section 2 as well as (11) and (12) determine, in a reduced form, the RHS of (15) as a function of  $a$ . Inspection of the relevant equations reveals that this function is continuous.<sup>21</sup> Call it  $H(a)$ . Next, note that as  $a$

<sup>21</sup>Note that  $J(m, \eta)$  has a discontinuity as  $m$  goes through  $\bar{m}$ . However what intervenes in the determination of the RHS of (15) is  $J(\bar{m}, \eta)$ , which is clearly continuous in  $a$ .

goes from any  $a_0$  to infinity, the  $\lambda'$ s are bounded from above by  $q(a_0)$ , while (3) implies that  $\Pi_e$  and  $\Pi_u$  go to zero. Consequently,

$$\lim_{a \rightarrow \infty} H(a) = 0.$$

Finally, if  $H(0) \leq C$ , then there exists an equilibrium such that  $a = 0$ ,  $u = 1$ , i.e. where no hiring is profitable. If not, then  $H(0) > C$ , in which case, by continuity, there exists an  $a$  such that  $H(a) = C$  and  $H(\cdot)$  is locally decreasing around  $a$ . Q.E.D.

Unemployed-Employed Difference in Differences		-0.052 (0.025)

Notes: The first and second rows in each panel of the table report average job finding rates for unemployed and employed workers covered and not covered by unjust-dismissal doctrines. Covered workers are those living in adopting states after adoption and uncovered workers are those living in non-adopting states and in adopting states before adoption. The third and fourth rows in each panel report differences of the average job finding rates. Standard errors are in parenthesis.

Table 4: Job Finding Results

		Sample											
		Basic controls				Basic + main effects, and region x time				Basic + main effects, region x time and UI			
Exception	Regressor	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)
Implied Contract	Effect on Employed	0.086 (0.005)			0.088 (0.009)	-0.013 (0.011)			-0.029 (0.03)	-0.009 (0.011)			-0.026 (0.034)
	Unemp. Interaction	-0.175 (0.001)			-0.174 (0.009)	-0.074 (0.033)			-0.062 (0.004)	-0.075 (0.039)			-0.06 (0.005)
Public Policy	Effect on Employed		0.064 (0.005)		0.046 (0.01)		0.059 (0.011)		0.069 (0.014)		0.069 (0.013)		0.077 (0.012)
	Unemp. Interaction		-0.091 (0.001)		-0.033 (0.01)		-0.032 (0.001)		-0.019 (0.019)		-0.048 (0.006)		-0.035 (0.021)
Good Faith	Effect on Employed			0.008 (0.006)	-0.053 (0.002)			-0.001 (0.009)	0.021 (0.016)			-0.001 (0.009)	0.021 (0.018)
	Unemp. Interaction			-0.073 (0.001)	0.046 (0.001)			-0.122 (0.048)	-0.099 (0.041)			-0.122 (0.048)	-0.114 (0.054)
Unemp. Main Effect		0.429 (0.025)	0.409 (0.028)	0.379 (0.01)	0.436 (0.018)	0.481 (0.247)	0.476 (0.365)	0.516 (0.172)	0.501 (0.433)	0.524 (0.21)	0.522 (0.327)	0.516 (0.172)	0.549 (0.39)

Notes: The table reports marginal effects from regressions of re-employment probabilities on the interaction terms and main effects listed in the regressor column. The interaction terms capture the effects of the exceptions on unemployed relative to employed workers. All models include: age, education, number of children, tenure, wage, non-wage income, local unemployment rate, a manufacturing dummy, a union dummy, a white-collar dummy, and dummies for race, sex, and marital status. Columns (5)-(8) include year effects, state effects, year-unemployed interactions, state-unemployed interactions, and region-time interactions. Column (9)-(12) include, in addition, an unemployment benefit receipt dummy. Robust standard errors are reported in parenthesis.

Table 5: Job Finding Results in Union and Non-union Samples

Exception	Regressor	Sample							
		Non-Union				Union			
		(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)

# Structural reforms in Italy: impact on growth and employment

STRUCTURAL REFORMS IN ITALY: IMPACT ON GROWTH AND EMPLOYMENT .....	1
KEY FINDINGS .....	2
QUANTIFYING THE EFFECTS OF THE REFORMS: DETAILS AND ANALYSES .....	3
THE IMPACT OF REFORMS ON THE PUBLIC DEBT-TO-GDP RATIO.....	7
ANNEX 1. REFORMS TAKEN INTO ACCOUNT IN THE QUANTIFICATION EXERCISE.....	8
REFERENCES .....	11

## Key findings

To improve Italy's long-term growth prospects, comprehensive structural reforms are needed to boost competitiveness and support job creation. Prime Minister Matteo Renzi's government has set out an ambitious structural reform agenda across many policy areas including product markets, labour markets, taxation, public administration and civil justice, among others. Some reforms have already been made, such as new provisions for labour contracts, revisions to unemployment benefits, some corporate tax reforms, and measures to improve administrative justice and anti-corruption policies. Others are under way but not complete, such as plans to improve active labour market policy, further administrative simplification and tax reforms. Still more are in the pipeline, such as further liberalisation and strengthening of competition, measures on education, public administration and criminal justice.

There has been an increased focus in Italy on rapid implementation: significant parts of the labour market reform were in place by the beginning of 2015. In addition, the backlog of subsidiary legislation from laws passed in 2012 and 2013 has been reduced significantly. Moreover, the government has also started to put great emphasis on changes in the political and institutional frameworks and judicial system to remove impediments to full implementation of reforms. Such institutional impediments in the past often deprived the economy of the full benefits of good reform projects due to a lack of their full implementation.

Drawing on the 2015 OECD Economic Survey of Italy, this paper provides a snapshot of the government's reform agenda. It also assesses the impact on productivity, employment and GDP of the reforms that have been introduced since 2012, which is estimated to have been significant. After five years, GDP will be 3.5% higher than would otherwise be the case in the absence of the reforms. This means that GDP will grow 0.7% faster per year on average over this period thanks to the reforms. The number of additional jobs created over that period is estimated at 340,000. In the following five years a further gain of similar magnitude can be expected. These estimates assume swift and full implementation of the reforms - delays, or less than full implementation, would reduce the gains.

- The *product market reforms* are estimated to boost GDP by around 1.5% after five years and 2.6% after ten years. This GDP increase is driven by higher productivity growth as lighter regulation encourages competition, which in turn speeds up the pace of convergence in productivity levels to the most technologically advanced economies. Lighter regulation also encourages firms to experiment with new ideas and technologies and improves facilitates the shift of resources from slow- to fast-growing sectors.
- The *labour market reforms* that the government is implementing as a result of the Jobs Act that was adopted in December 2014 are expected to boost GDP by 0.6% after five years and 1.2% after ten years. The positive GDP effect comes through higher employment, with 150,000 new jobs created after five years and 270,000 new jobs created after ten years. The reforms focus on four key areas: rationalising employment protection, expanding active labour market policy, making social protection more effective, and boosting female labour force participation.
- The *tax reforms* are expected to boost GDP by 0.7% after five years and 1.6% after ten years. The effect of the personal income tax cut for low-income earners will come through higher employment, which is estimated to increase by 180,000 jobs after five years and 380,000 jobs after ten years. The 10% cut in the tax on productive activities affecting businesses, the exclusion of workers' pay from the base of that tax, and the strengthening of the tax credit for hiring personnel with a PhD or engaged in R&D activities will affect GDP through higher productivity.
- The government is also making wide-ranging reforms to the *public administration* and the *judicial system*, which will boost GDP both directly by reducing administrative burdens on firms and indirectly by securing the timely and complete implementation of other reforms. Among the various reforms in this area, only the impact of the creation of single access points for foreign investors can be quantified in this paper. The reform is expected to increase the level of GDP by 0.6% after five years and 0.9% after ten years by easing the entry of foreign firms.

## Quantifying the effects of the reforms: details and analyses

After a long period of stagnation, Italy has started to undertake ambitious reforms to boost growth. This paper offers an estimate of the impact of improving the countries' product and labour market regulations, the structure of its tax system as well as its public administration and judicial system on productivity, employment and GDP. The assessment suggests that the reforms could increase the level of GDP by 3.4% within five years and by 6.3% within ten years (Table 1). At the 10-year horizon, about 40% of the effect is due to higher employment, while the remaining part is due to higher productivity. Details on the reforms considered are found in Annex 1.

**Table 1. Impact of reforms on the level of productivity, employment and GDP**

in percent

	Impact after five years			Impact after ten year2		
	GDP	Via employment growth	Via productivity growth	GDP	Via employment growth	Via productivity growth
Product market reform <sup>1</sup>	1.5		1.5	2.6		2.6
Labour market reform (Jobs Act) <sup>2</sup>	0.6	0.5	0.1	1.2	1.1	0.1
Tax reform	0.7	0.5	0.2	1.6	1.6	0.0
Public administration and judicial system reform	0.6		0.6	0.9		0.9
Total	3.4	1.0	2.4	6.3	2.7	3.6
<i>Average annual growth</i>	<i>0.7</i>	<i>0.2</i>	<i>0.5</i>	<i>0.6</i>	<i>0.3</i>	<i>0.4</i>

Notes:

1. OECD estimates for the impact of product market reform include the results of reforms from 2012 onwards. Approximately two thirds of the quoted impact are due to measures taken in 2012-13.
2. The impact of the labour market reform is based on a judgement, based on the Jobs Act Legge Delega (enabling law), although not all details are defined yet.
3. Reforms that are planned (and announced) for 2015 and 2016, or in 2014 but not yet legislated in detail, have not been included, with the exception of those under the Jobs Act as described in note 2.
4. The employment effects assume that all persons entering the labour market find work.

Source: OECD calculations.

The quantitative assessment is based on a previous work by the OECD for the G20 which evaluated the Comprehensive Growth Strategy by the Italian government. This previous work looked at the reforms announced and adopted in 2014. This time, the quantitative assessment broadens the scope so that it also includes:

- past reforms for which the current government is responsible in their implementation;
- additional measures which have been announced and adopted since the previous work for the G20 (among others, the 2015 budget as well as the Jobs Act enabling law and its application decrees).

The quantitative assessment therefore adopts the same methodology as in the previous work for the G20. It investigates the expected effects from each reform measure. First, each reform measure is evaluated in terms of quantifiable variables, including standard OECD indicators where necessary. These indicators are typically the Product Market Regulation (PMR) indicators and the Employment Protection Legislation (EPL) indicators. Then a series of equations relate each reform measure or packages thereof to their expected effects on productivity and/or employment. These effects are added up to produce the total effects.

The quantitative assessment primarily focuses on reform measures for which the estimated effects are relatively well-established and straightforward to be understood. It relies on existing OECD empirical studies of the links between structural policies and productivity or employment, and covers the following areas: *i*) product market reform; *ii*) labour market reform (employment protection legislation, unemployment benefits, active labour market policies, female labour force participation), and *iii*) tax reform. Reforms of the public administration and the justice system are taken into account where possible (for example, those which apparently improve the functioning of the product or labour market and are possible to be interpreted in terms of the standard OECD indicators).

### Product market reform

Reforming product market regulation (PMR) in a way to enhance competition can speed up the pace of convergence in productivity levels to the most technologically advanced economies. More competition encourages firms to pursue efficiency and invest in innovation and knowledge-based capital. Lowering barriers to entrepreneurship facilitates the entry of firms that experiment with new ideas and technologies. PMR reforms can also boost aggregate productivity by raising the capacity of the economy to allocate capital and labour resources to fast-growing sectors. Product market competition can also be good for jobs by encouraging the creation of new companies and the expansion of existing ones that can take advantage of new markets, products or processes.

Italy's product market does not seem to function in a competitive way, given the limited number of start-ups. The resource allocation mechanism is impaired, as it does not channel resources to the most productive firms. To tackle this issue, a number of reforms to the competition and regulatory frameworks were launched. Specifically, the government significantly extended the powers of the Antitrust Agency and established new independent regulators in transport sectors. In addition, regulatory restrictions in professional services and retail trade were eased, market access in the telecom sector was improved and the unbundling requirements in the gas sector were strengthened. Italy is also committed to implement reforms as part of the completion of the European Telecom Single Market, the Third EU Energy Package and the EU's commitment to open the railway market for competition. Together, the already implemented reforms and the reforms to which Italy is committed because of EU membership should boost productivity and GDP by around 1.5% within the first five years after the reforms and by another 1.1% within the following five years.

### Labour market reform

With the Jobs Act adopted in December 2014, the government has a mandate to introduce measures to rationalise employment protection, expand active labour market policy, make social protection more effective, and boost female labour force participation:<sup>1</sup>

- Less stringent *employment protection legislation* (EPL) promotes an efficient allocation of labour resources by making it easier for firms to respond quickly to changes in technology or product demand that require reallocation of staff or downsizing. Therefore, EPL reforms that reduce the costs of hiring and firing can support higher productivity. Indeed, stringent EPL has been found to weaken productivity in sectors where labour turnover is "naturally" high (Bassanini et al., 2009). To rebalance job protection, a standard contract with employment protection increasing with tenure was introduced in early 2015. This new arrangement implies quite radical changes for Italy and to avoid unwarranted disruption, it is applied only to new employment contracts ("grandfathering" existing rights). As part of the Jobs Act the government also introduced a new form of out-of-court procedure for dismissals, under which the employer pays the worker an indemnity equal to 1 monthly wage per year of service. The acceptance of this transaction prevents any further dispute by the worker. Both parties have a strong incentive to settle the dispute through this procedure, since the sum paid is not subject to social contribution or fiscal taxation.
- *Active labour market policies* (ALMPs) aim to improve the efficiency of the matching process in the labour market, reducing frictions in vacancy filling by assisting job seekers. ALMPs act on recruitment costs (through job counselling, placement services, etc.) as well as on after-tax wages (making work pay). Such

---

1. The Jobs Act also foresees the introduction of a legal minimum wage, but no details have yet been announced.

measures encourage firms to open new vacancies and unemployed workers to accept jobs. The Jobs Act will strengthen ALMPs and create a National Employment Agency, which will be responsible for coordinating ALMP policy. So far, only parts of the reform have been legislated.

- An efficient *social benefit system* is important so that displaced workers are protected against poverty and given facilities to help finding new jobs, while avoiding pervasive disincentives for labour supply. In Italy, the unemployment benefit system has been very generous for certain workers, notably those in the industrial sector, while other workers have had little cover. As part of the Jobs Act the coverage of unemployment benefits was extended, bringing Italy closer to a “flexicurity” approach. Moreover, the “Assicurazione Sociale per l’Impiego” (ASpl) and mini-ASpl which were introduced in 2012 were integrated, thus harmonising their different eligibility requirements and durations. The new legislation also introduced conditionality for unemployment benefits, requiring recipients to participate in activating measures proposed by the employment service, and reforms the social assistance provided to vulnerable people.
- The *female labour force participation* rate has been increasing steadily, due to the cohort effect reflecting higher educational attainment of the current generation, and is expected to continue doing so. However, its level still remains well below the OECD average. Encouraging greater participation is very important for Italy, since the working age population will soon begin to diminish due to demographic factors, while immigration is expected to have a very limited influence over the long run. Family-friendly policies and working conditions which enable fathers and mothers to balance their working hours and their family responsibilities facilitate women’s labour force participation or longer working hours. To encourage female labour force participation, the Italian government is planning to reshape tax deductions for dependent spouses, reform maternity allowances and improve the availability of care facilities. Moreover, it has introduced a tax credit for low- and medium-income families with children.

Many of the above listed elements of the Jobs Act can be quantified in terms of their impact on productivity, employment and GDP. This includes all EPL reforms with the exception of the new out-of court settlement procedure, all ALMPs reforms, the strengthening of the link between unemployment benefits and individual job-search efforts, and all measures to foster female labour force participation. Together, these reforms will boost GDP by 0.6% in the first five years after the reform. In the following five years an effect of similar magnitude is expected, so that the total GDP effect after ten years amounts to around 1.2%. The majority of this effect comes through higher employment. The Jobs Act is estimated to create around 150,000 new jobs in the first five years after the reform and another 120,000 jobs in the following five years.<sup>2</sup> This assumes that the ALMP that have not been legislated so far and the reforms to strengthen the participation of women will be legislated in due course.

### Tax reform

High taxes on labour income depress labour supply and can reduce firms’ labour demand by driving up the cost of labour (due to high employers’ contributions or payroll taxes). Such detrimental effects are stronger for young and low-skilled workers facing foremost labour demand-side obstacles, and second earners and lone parents often facing high disincentives for full-time labour participation. Therefore, reforms that reduce the labour tax wedge can increase employment and also reduce labour informality (Bassanini and Duval, 2006). As part of its reform agenda, the government cut the personal income tax for low-income earners. The reform will create around 180,000 jobs within the first five years of the reform and additional 200,000 jobs within the next five years. The greater labour supply will boost GDP by 0.3% within the first five years and by another 0.9% within the following five years.<sup>3</sup>

Tax reforms can impact economic growth also via private investment and productivity (Arnold et al., 2011; Bouis et al., 2012). A more growth-friendly tax system can be achieved by shifting the tax burden away from

---

2. The contribution of employment growth to GDP growth is disproportionately larger at the 10-year horizon than at the 5-year horizon despite the similar pace of employment growth because the 10-year effect assumes that the capital stock increases by as much as employment to recover the pre-reform level of the return to capital.

3. The much larger contribution of employment growth to GDP growth at the 10-year horizon relative to the 5-year horizon is again due to the capital stock adjustment that feeds through only in the long run.

direct income toward consumption, immovable property and the environment. In this spirit, the Italian government cut the regional tax on productive activities (IRAP) affecting businesses by 10% in 2014, from 3.9% to 3.5%. In addition, the 2014 Budget Law strengthened the tax credit for hiring personnel with high skills to facilitate the employment of persons with a PhD or engaged in R&D activities and extended the tax credit for investments in R&D. The government is also working to pass a law (“delega fiscale”) aimed at reforming the cadastre and defining a more equitable, transparent, simplified and growth-oriented tax system, while ensuring stability and legal certainty. The measures to modernize and make the tax code more growth friendly are needed complements to the crowding in effect from the spending review. Together, these measures are estimated to raise the levels of productivity and GDP by 0.4%, with the full impact of the reforms seen already after five years. This assumes that also the “delega fiscal” will be rapidly and fully legislated.

### **Reform of the public administration and the judicial system**

Important steps have been taken to improve the efficiency of the judicial system. The government has modified the application of the statute of limitations to reduce the incentive to prevarication and took measures to gain economies of scope and scale through the amalgamation of small courts, thus allowing some specialisation by judges. Other measures already legislated include the strengthening of mechanism of alternative dispute resolution and making greater use of ICT to simplify judicial processes and make them more efficient. The government is also planning to establish specialised business courts.

The government is also planning to reform the public administration, progressively lowering the mean working age of civil servants, launching a new system for public management and a national plan for workers’ mobility and adopting measures to enhance integrity. In addition, the public administration is to be reorganized to achieve cost savings, the efficiency of public procurement is to be strengthened, and governance is to be simplified and improved to attract more foreign direct investment.

As the quantitative assessment only considers reforms which directly impact productivity and/or employment, the coverage of reforms related to the efficiency in public administration and the justice system is limited. The only reform that is taken into account is the creation of single access points for foreign investors, which increases productivity by facilitating the dialogue with the public administration in the preparation of investment solutions as well as by guaranteeing the legality of investment-related regulatory practices at all stages of the investment process and the stability of contracts. Assuming that that the measure is fully implemented in due course, it will boost GDP by almost 0.6% within the five years of the reform and by an additional 0.3% within the following five years.

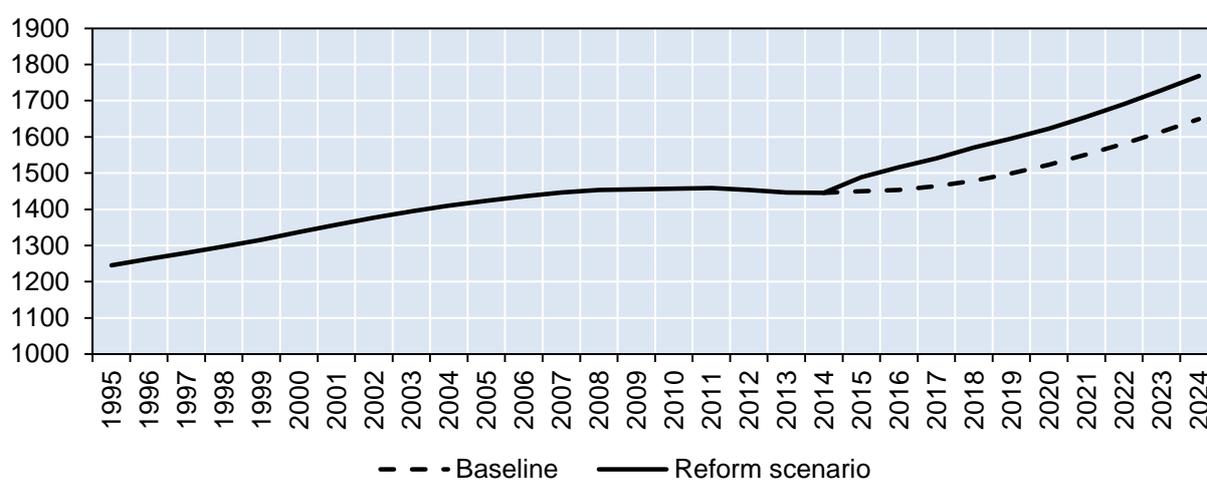

## The impact of reforms on the public debt-to-GDP ratio

The reform package can be considered in an integrated macroeconomic framework, using the OECD Economic Department's long-term baseline model. This framework allows computing the trajectories of GDP, public finances and the current account balance in a consistent way, while taking into account the reform measures jointly with other macroeconomic forces.

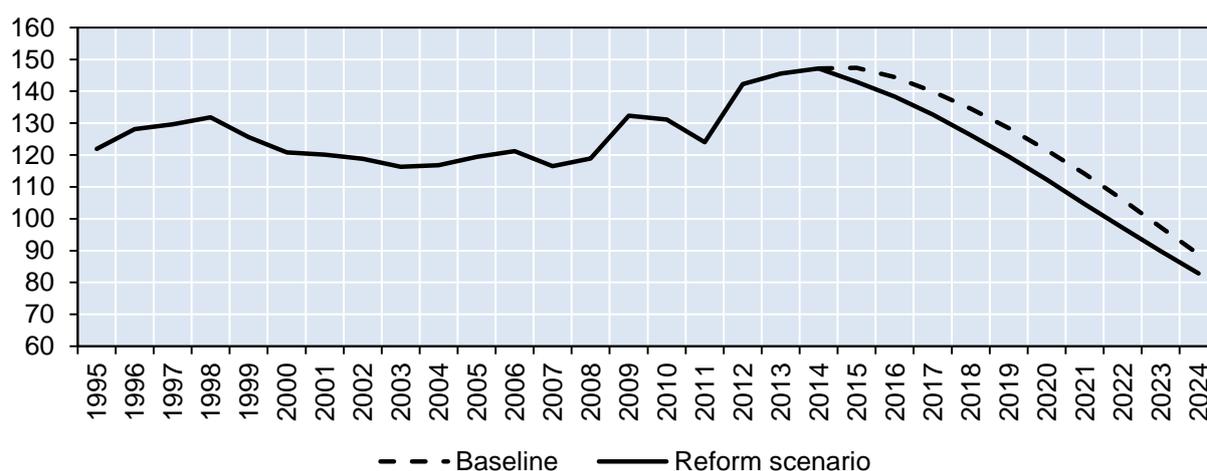

In association with higher growth rates, the reforms will lower the debt-to-GDP ratio. The path of the debt-to-GDP ratio is now lower compared with the baseline scenario in each period, with the difference narrower as the 60% target is being reached. This difference arises to a large extent from the employment side. The result is underpinned by a long-term equality between government and private sector wages, as well as program expenditures that are linked to economic growth through indexation on wage increases (for details, see Chapter 4 in OECD, 2010).

**Figure 1. The reforms will accelerate the reduction in the debt-to-GDP ratio**

A. Potential GDP in billion EUR (constant 2005 prices)

B. Debt-to-GDP ratio in %

## Annex 1. Reforms taken into account in the quantification exercise

Reform area	Reform content
Product market reforms	
Antitrust Agency	The powers of the Antitrust Agency (AGCM) have been significantly extended. It can now appeal through the regional administrative court (TAR) against the actions of any public administration at the national, regional or local level violating the principles of competition. To raise the incentives of local authorities to award services through public tender, exclusive contracts for local public service provision in municipalities with more than ten 000 inhabitants have been subjected to a mandatory opinion by the AGCM regarding the existence of suitable and sufficient reasons for assigning such exclusive rights.
Regulatory oversight	In transport, the Cresci Italia law from March 2012 legislated to establish a new independent regulatory authority, to be responsible for highways, airports, ports, taxis and railways both at the national and local level. The surveillance of the water and postal sectors has been assigned to the Energy and Communication Authorities, respectively.
Telecom sector	The Communications Authority (AGCOM) approved the break-up of the fixed telecommunications infrastructure owned by Telecom, in order to ensure to all operators access to the network at non-discriminatory rates.
Gas sector	The further unbundling of the gas network operator (SNAM) from the incumbent gas operator (ENI) should create more effective competition and transparency in the market for natural gas.
Professional services	Some restrictions to professional services have been reduced. For example, standard pricing has been eliminated and it has become easier for young people to begin practising, by allowing them to complete part of the compulsory practical training in parallel with university education. Pharmaceutical distribution services have been enhanced through an increase in the number of pharmacies (one per 3 300 inhabitants), and allowing the sale of certain pharmaceuticals outside pharmacies. On the other hand, the period within which a person inheriting a pharmacy, but who is not enrolled in the profession's register, must sell the property was shortened from 2 years to 6 months, providing members of the register with greater leverage in sales negotiations.
Retail trade	In retail trade, the Salva Italia law has extended the freedom of opening hours to all shops, not only those located in tourist resorts or artistic cities, and has reduced unjustified restrictions on the exercise of a business activity, such as minimum distances between commercial outlets.  Fuel distribution at the retail level has been substantially deregulated by allowing petrol stations to source part of their supply from producers other than their mother company, removing limitations to self-service at stations outside cities and to locating near supermarkets, and expanding the range of articles that are allowed to be sold at petrol stations.
EU commitment on Single Telecom Market	A legislative package for the completion of the European Telecom Single Market was voted by the European Parliament in April 2014 and has to be approved by the EU Council. The proposed package would strengthen network neutrality rules across borders and cut international roaming charges in the EU. Following an agreement reached with the EP in February 2014, the Council adopted the Directive on broadband cost reduction on 8 May. EU Member States must now adopt national provisions to comply with the new Directive by 1 January 2016 and they must apply the new measures from 1 July 2016.

EU commitment in the energy sector	In the energy sector the priority for the coming years should be the completion of the energy internal market through the transposition and implementation of the Third Energy Package, which should be achieved by the end of 2014. Its major elements concern the unbundling of networks, the strengthening of the independence and power of national regulators, and the improvement of the functioning of retail markets. Fees for the purchase of natural gas have also been made more competitive, and the Electronic Markets Operator (GME) is developing a platform for the logistics market for oil and mineral oils to bolster competition in the oil industry.
EU commitment in rail transport	In transport, the main priority is the opening of the railway market for competition through, among other things, the separation between infrastructure and services and open procedures for public service obligations. These issues are addressed by the Fourth Railway package proposed by the European Commission. In June 2014, the Council reached political agreement on the draft directives on the interoperability and safety of European railways and the draft regulation on the European Railway Agency. Together, these three legislative acts make up the technical pillar of the Fourth Railway package. The rules regarding the fees for access to the railway network have changed so as to guarantee to all competitors non-discriminatory access to the market.
<b>Labour markets reforms</b>	
Active Labour Market Policies	The Jobs Act strengthens employment services and active policies by: a) establishing a National Employment Agency for the integrated management of active and passive labour policies; b) strengthening and enhancing public-private partnerships; c) ensuring a proper division of labour between the national level, in charge of defining the basic level of assistance, and the local authorities, in charge of planning active labour market policies; d) ensuring the active involvement of job seekers; e) improving the IT system for managing and monitoring purposes.
Unemployment Benefits	Taking over the previous reform in 2012, the Jobs Act ensures the unification of the standard unemployment benefit and some specific benefits ( <i>Indennità di Mobilità</i> for collective dismissal, for example). It will also phase out other specific benefits (for example, <i>Cassa Integrazione Straordinaria</i> , for those who work in firms facing crisis and/or restructuring in the industry sector or other designated sectors, whose replacement ratio and duration have been more generous than the standard unemployment benefit).
Employment Protection Legislation	<p>For fixed-term contracts lasting up to 3 years (instead of 1 year before the reform), employers no longer need to specify the reason of the termination of the contract.</p> <p>For businesses employing more than a certain number of employees, the maximum share of the total workforce that can be subject to this contract is 20 per cent; for businesses employing less than a certain number of employees there is no limit to the use of this contract typology. The ability to modify the quantitative limit of 20 per cent and the possibility of deviating from the 20 per cent threshold for reasons connected with replacement and seasonality are left to collective bargaining. The possibility to extend the duration of the contract period within the limit of 36 months was also extended from one to eight times.</p> <p>A new standard employment contract was introduced, implying less rigid dismissal protection than the previous open-ended contract. This new standard contract limits further the possibility of reinstatement of workers following unfair dismissal and excludes this possibility for the case of redundancy (dismissal for objective reasons "motivo oggettivo"). Instead, workers unfairly dismissed for objective reasons receive monetary compensation. This monetary compensation increases with tenure: equal to 2 monthly wages per year of service (a minimum amount equivalent to 2 months and a maximum amount equivalent to 24 monthly wages).</p>

Labour force participation	The Jobs Act aims at: a) introducing a universal maternity allowance (guaranteeing the right to mothers working under a non-standard contract to benefit from a maternity allowance even in the event of non-payment of contributions by the employer); b) introducing a tax credit for low- and medium-income families with little children; c) supporting collective agreements designed to facilitate flexible working conditions; d) facilitating an integrated provision of services to childhood by companies within the public-private system of personal care services.
----------------------------	---

#### Tax Reforms

Labour tax wedge	The government introduced a EUR ten billion overall tax reduction benefitting low-income dependent workers with an annual labour income of less than EUR 26000. A lump sum tax reduction equivalent to EUR 80 per month is paid on incomes up to EUR 24000, and gradually phased out as labour income attains EUR 26000. This tax reduction is estimated to benefit about ten million employees (those with a take-home pay of less than EUR 1500 per month). The government financed this measure broadly in a finance-neutral way. This measure is extended to the year 2015 and will become permanent.
------------------	---

Tax structure	<p>The tax on productive activities (IRAP) (affecting businesses) was cut by ten percent.</p> <p>The 2015 Budget Law a) strengthened the tax credit for hiring personnel with high skills and b) extended the tax credit for investments in R&amp;D.</p> <p>The government is also working to pass a law (“delega fiscale”) aimed at reforming the cadastre and defining a more equitable, transparent, simplified and growth-oriented tax system, while ensuring stability and legal certainty.</p>
---------------	--

#### Reform of the Public Administration and Judicial System

	The administrative burden will be reduced through the creation of a single access point to facilitate entry of foreign investors: facilitating the dialogue with the public administration in the preparation of investment solutions, and guaranteeing the legality of investment-related regulatory practices at all stages of the investment process and the stability of contracts.

## **ORGANISATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT**

The OECD is a unique forum where governments work together to address the economic, social and environmental challenges of globalisation. The OECD is also at the forefront of efforts to understand and to help governments respond to new developments and concerns, such as corporate governance, the information economy and the challenges of an ageing population. The Organisation provides a setting where governments can compare policy experiences, seek answers to common problems, identify good practice and work to co-ordinate domestic and international policies.

The OECD member countries are: Australia, Austria, Belgium, Canada, Chile, the Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Israel, Italy, Japan, Korea, Luxembourg, Mexico, the Netherlands, New Zealand, Norway, Poland, Portugal, the Slovak Republic, Slovenia, Spain, Sweden, Switzerland, Turkey, the United Kingdom and the United States. The European Union takes part in the work of the OECD.

OECD Publishing disseminates widely the results of the Organisation's statistics gathering and research on economic, social and environmental issues, as well as the conventions, guidelines and standards agreed by its members.

## Key lessons for labour market reforms: evidence from OECD countries' experiences

Jørgen Elmeskov, John P. Martin, and  
Stefano Scarpetta\*

### Summary

■ Since 1992, the OECD has been intensively researching into the causes and consequences of high, persistent unemployment and effective remedies to tackle it. In particular, since the *Jobs Study* was published in 1994, the OECD has elaborated detailed policy recommendations for each of its member countries and closely monitored their progress (or lack of it) in implementing these recommendations. This process identified six countries that have succeeded in reducing unemployment significantly in the 1990s, together with a few other countries that have maintained unemployment at relatively low levels.

The purpose of this paper is to distil the lessons for labour market reforms from the *successes* and *failures*. It begins by discussing the structural unemployment indicator that the OECD has used to identify the successful countries. This is followed by a review of the cross-country determinants of structural unemployment that focuses on the role of labour market policies and certain institutional factors. One novelty is the specific attention paid to potential interactions between labour market policies and institutional features of the collective bargaining system. The paper also highlights several key lessons for labour market reforms drawing on recent OECD research. In particular, it discusses the role played by labour market insiders in the process of reform. It considers the way in which concerns about the equity effects of labour market reforms have played a role in shaping policies. Finally, it discusses the role of crises as a potential catalyst for needed reforms. ■

\* Jørgen Elmeskov and Stefano Scarpetta are, respectively, deputy director and principal administrator in the OECD Economics Department. John P. Martin is deputy director in the OECD Directorate for Education, Employment, Labour and Social Affairs.

## Key lessons for labour market reforms: evidence from OECD countries' experiences

Jørgen Elmeskov, John P. Martin and Stefano Scarpetta\*

High and persistent unemployment has been a major blot on the economic and social record of most OECD countries during the past two decades or more. In 1992, OECD ministers gave the organisation a mandate to analyse the causes and consequences of high and persistent unemployment and propose effective remedies to tackle the problem. The first fruits of this work, published in 1994 under the title *The OECD Jobs Study*, included a list of more than 60 detailed policy recommendations backed by two volumes of research; see OECD (1994a, 1994b). Ministers then mandated the organisation to continue its analytical work in certain areas. They also asked the organisation to flesh out detailed policy recommendations for each OECD country (considering each country's historical, institutional and political contexts) and to monitor progress in the implementation of these recommendations and their impacts on labour market performance.<sup>1</sup>

The OECD work since 1994 has produced a series of additional publications; see OECD (1996a, 1996b, 1997a). This work culminated in a major report in 1997, *Implementing the OECD Jobs Strategy: Member Countries' Experience*.<sup>2</sup> And it enabled the organisation to identify several country success stories and failures in terms of implementing OECD recommendations and the resulting labour market

\* We acknowledge helpful comments from Lars Calmfors, the referee, and participants at the Stockholm conference. We are grateful to Martine Levasseur for statistical assistance and to Léa Duboscq for secretarial assistance. The views expressed in this paper are our own and should not be held to represent those of the OECD or its member governments.

<sup>1</sup> The results of this monitoring exercise were published in OECD Economic Surveys of individual countries.

<sup>2</sup> OECD (1998a) presents a short update of the 1997 report.

outcomes. In assessing needs for reform, the work relied heavily on the econometric analysis in Scarpetta (1996) that quantified the role of a range of labour market policies and institutional factors in explaining differences in unemployment rates across OECD countries.

The aim of this paper is to distil the main lessons for labour market reforms from the successes and failures revealed by recent OECD research. In short, the paper tries to answer this question: Why did a few OECD countries succeed in the task of significantly reducing structural unemployment during the past decade while most have failed so far?

The paper has three main sections. Section 1 presents estimates of the structural unemployment rate indicator that the OECD used to identify successes and failures and briefly discusses its pros and cons. This is followed by a review of the main determinants of unemployment rates across countries, which is essentially an update and extension of the cross-country results in Scarpetta (1996). In particular, it focuses on possible interactions between labour market policies and institutional features of the collective bargaining system. Section 3 highlights some key lessons for labour market reforms revealed by OECD research. The final section contains concluding remarks.

## **1. Identification of country successes and failures**

### **1.1. Structural unemployment rates**

Because the ultimate goal of policy is to reduce high and persistent unemployment, it is natural to use an unemployment-rate measure as the criterion to distinguish success from failure. To abstract from business-cycle effects, the OECD opted for a measure of the structural or equilibrium unemployment rate as its criterion. Table 1 presents estimates of the *non-accelerating wage rate of unemployment* (NAWRU) that indicate the possible level and evolution of non-cyclical unemployment in OECD countries over the past decade; see Appendix A.

Estimates of the NAWRU are used to split the OECD countries into three groups consisting of countries where structural unemployment has: (1) increased during the 1990s; (2) shown little change; and (3) decreased. (A change in the structural unemployment rate between 1990 and 1997 is considered significant, and hence determines which of the three groups a country is assigned to, if it exceeds one standard deviation.)

**Table 1. Structural unemployment in the OECD countries as a per cent of the total labour force<sup>a</sup>***In the 1990s, the structural unemployment rate has...*

<i>...increased in</i>	1986	1990	1997
Finland	5.5	7.0	12.8
Sweden	2.1	3.2	6.7
Germany	7.3	6.9	9.6

Ireland	14.6	14.6	11.0
OECD structural unemployment rate <sup>b</sup>	6.9	6.8	7.1
OECD actual unemployment rate <sup>b</sup>	7.7	6.0	7.5

*Notes:*

<sup>a</sup> Structural unemployment data are based on estimates of the NAWRU made for the *OECD Economic Outlook*, 63, 1998. A change is considered significant (in absolute terms) if it exceeds one standard deviation. The latter was calculated for each series and country during the 1986-97 period.

<sup>b</sup> Weighted averages of the countries reported in the table.

*Source:* OECD Secretariat.

These estimates suggest that structural unemployment rates significantly increased in the 1990s in 10 countries, including Sweden, remained stable in another six, and significantly declined in the remaining six countries. This latter group, designated the success stories for the purposes of this paper, consists of Australia, Denmark, Ire-

land, the Netherlands, New Zealand, and the UK. Note that the success stories are not confined to English-speaking countries but also include two continental European countries: Denmark and the Netherlands. Several countries in the second group in Table 1 also managed to maintain structural unemployment rates at relatively low levels. This group includes Japan, Norway, Portugal, and the US. OECD (1997b) argues that some of these countries managed to maintain low structural unemployment because their policies in important respects followed the main thrust in the *Jobs Strategy*, though with clear differences of emphasis among countries. Also note that some of the countries in the first group, e.g., Austria, Iceland, and Switzerland, while experiencing rising structural unemployment in the 1990s, managed to maintain relatively low levels of unemployment.

### **1.2. The pros and cons of using estimates of structural unemployment rates as an indicator of success or failure**

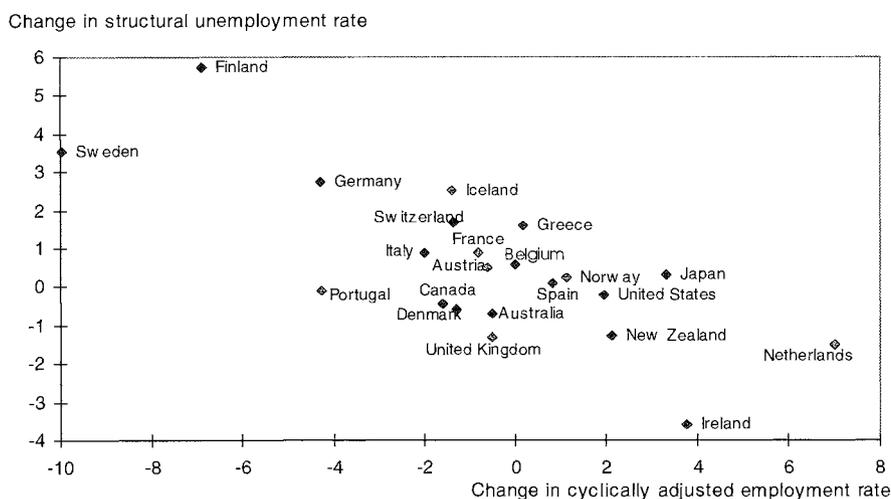

Because by definition the structural unemployment rate is an unobservable variable, serious questions can be raised about its use in this way to classify cross-country performance. And many economists question the analytical usefulness of the concept itself—witness the different views expressed on the concept in a symposium in the *Journal of Economic Perspectives*, Winter 1997.

Because differing views on the use of the concept for analytical and empirical purposes are well known, we do not rehearse the case again. All we are saying is that the OECD Secretariat has found the concept to be a useful one in its analyses of the unemployment problem, and the relevant OECD bodies that oversee work on implementing the OECD *Jobs Strategy* largely share this view.<sup>3</sup> Even if one accepts that the concept is a useful analytical device, there still remains the issue of deriving satisfactory empirical proxies for it. The previously cited OECD work has opted to proxy the structural unemployment rate by estimates of the NAWRU. Of course these time-varying estimates of NAWRUs are somewhat fragile, but similar concepts based on the unemployment rate that is associated with some average vacancy rate or some average capacity-utilisation rate, tend to give broadly similar numerical estimates (Elmeskov, 1993). The OECD NAWRU estimates are broadly aligned with those of other

<sup>3</sup> Here, it is interesting to note the trenchant defence of the concept by Stiglitz (1997). He was formerly chairman of the OECD's Economic Policy Committee.

studies.<sup>4</sup> We also examined the correlations between changes in estimated structural unemployment rates during the 1990-97 period with corresponding movements in a range of *observable* labour market indicators, such as long-term unemployment, unemployment rates for low-skilled workers, and employment rates (OECD, 1997b). In all cases, relatively high correlation exists between movements in the different series. Figure 1 illustrates the correlation between changes in structural unemployment and changes in the cyclically adjusted employment rate.

**Figure 1. Change in the structural unemployment rate plotted against the change in the employment rate, 1990-97**

*Note:* Correlation coefficient = -0.7. t-statistic = -5.0. The cyclically adjusted employment rate was estimated by regressing the actual employment/population ratio against an estimate of the output gap based on the proportional difference between actual and trend output. The latter has been estimated using a Hodrick-Prescott filter.

<sup>4</sup> See the set of country studies on "The NAIRU: Concept, Measurement and Policy Implications" in the *OECD Economics Department Working Papers* series. However, Holden and Nymoer (1998) argue that estimates of rising NAWRUs for the Nordic countries may be misleading. While some of their conclusions may reflect conceptual differences in the definition of structural unemployment, and the strength of their evidence may be assessed differently, it must be acknowledged that estimates of structural unemployment are particularly uncertain where economies were subject to large shocks, as was the case in Finland and Sweden in the early 1990s.

In sum, while OECD estimates of structural unemployment rates are subject to conceptual and numerical uncertainties, the evidence suggests that changes in estimated structural unemployment rates in the 1990s matched real changes in labour market conditions in OECD countries. This, in turn, suggests that the three-way classification of countries in Table 1 permits a meaningful identification of successes and failures.

## 2. Determinants of structural unemployment in OECD countries

The preceding section identifies several countries that have either maintained low structural unemployment rates during the past decade or have managed to significantly reduce them. This section explores the possible determinants of the significant cross-country disparities in structural unemployment rates, drawing on the Scarpetta (1996) approach. Our empirical analysis extends Scarpetta's work in three main directions by:

- Considering a larger number of countries (from 17 to 19) and extending the time period;
- Exploiting recent information on the evolution of collective bargaining structures and employment protection legislation (EPL);
- Focusing on potential interactions between labour market policies and institutional factors.

### 2.1. A reduced-form unemployment equation

The theoretical framework for the analysis follows the familiar Layard-Nickell-Jackman (1991) model characterised by an upward sloping *wage-setting* schedule, based on the assumption that real wages are the results of a bargaining process between employers and employees, and a downward-sloping *labour-demand* schedule. Product market conditions, including the price mark-up over marginal costs, influence the latter, while a range of wage-push factors influence the wage-setting schedule.

It can be easily shown that the intersection of the labour demand curve and the wage-setting schedule identifies the structural (or equilibrium) unemployment rate and the equilibrium level of real wages. In this framework, structural unemployment is a function of wage-push factors, price-push factors, and the elasticities of real wages and price mark-ups to unemployment.

In our empirical analysis of the determinants of structural unemployment, we tested several potential wage- and price-push factors, including income-support schemes for the unemployed; active labour market policies; the tax wedge; EPL; the structure of collective bargaining; and minimum wages.<sup>5</sup> To quantify the relative importance of these policy and institutional variables in determining the wide disparities in structural unemployment across OECD countries, we estimated a static model over the 1983-1995 period. The period corresponds, more or less, to a full business cycle, over which structural unemployment has changed only moderately in most OECD countries, at least compared with the sharp increases of the 1970s and early 1980s. This is also the period for which most of the information is available on labour market institutions and labour market policies.

Pooling data for 19 countries<sup>6</sup> over the 1983-95 period and adding an explanatory variable to account for the effects of aggregate demand fluctuations over the cycle,<sup>7</sup> the determinants of the actual unemployment rate were modelled by a reduced-form equation with this structure:

$$u_{it} = \mu_0 + \mu_i + \sum_k \beta_k x_{kit} + \gamma z_t + \phi g_{it} + \nu_{it} \quad (1)$$

where  $i$  indexes countries,  $t$  the years,  $u$  is the unemployment rate,  $x$  denotes a set of time-varying explanatory variables,  $z$  is our measure of public spending on active labour market policies per unemployed person,<sup>8</sup>  $g$  is the output gap included to account for changes in the

<sup>5</sup> The OECD has produced quantitative indicators for each of these factors (see Scarpetta, 1996, for definitions and sources for all the variables except statutory minimum wages, which are described in OECD, 1998b). We used these data as regressors in our reduced-form unemployment equation.

<sup>6</sup> The set of 19 countries includes: Japan, western Germany, France, Italy, Canada, Australia, Austria, Belgium, Denmark, Finland, Ireland, Netherlands, New Zealand, Norway, Portugal, Spain, Sweden, the US and UK.

<sup>7</sup> Different variables are used in the literature to proxy aggregate demand effects. Layard and Nickell (1997) and Phelps (1994) used changes in inflation, while Coe (1990) used changes in capacity utilisation, as did Sargent and Sheikh (1996) who also included the output gap in their equation. We used the latter variable but also tested for the effects of replacing it by the change in inflation. The results were less satisfactory, most likely because in some countries factors other than aggregate demand (e.g., changes in macroeconomic policy regimes or income policy agreements) affected inflation.

<sup>8</sup> By construction, active spending per unemployed relative to GDP per worker (ALMPU) is highly endogenous and must be instrumented. We used the average of ALMPU over the entire sample period as the instrument. We also experimented

business cycle,<sup>9</sup>  $\mu_0$  is a constant,  $\mu_i$  is the country-specific effect not accounted for by the available explanatory variables, and  $v$  is the usual error term.<sup>10</sup> Table B1 shows the key characteristics of the data set (see Scarpetta, 1996 for more details).

Table 2 presents the results of estimating different specifications of the reduced-form, unemployment-rate equation. The first three columns of the table focus, in turn, on key features of collective bargaining arrangements—namely, the degree of co-ordination in bargaining (column 1), the predominant bargaining level at which wages are negotiated (centralisation/decentralisation) (column 2), and a summary measure that combines the degree of centralisation/co-ordination (column 3).<sup>11</sup> Column 4 introduces the tax wedge in the

with using government spending (less net interest paid and labour market spending) as the instrument: first active spending as a share of GDP was instrumented with government spending, and then the instrumented variable was normalised with a smoothed employment/unemployment (E/U) ratio. The approach was not pursued because of the limited power of government spending in explaining the variations in active spending in some countries, and because the explanatory power of the overall instrument variable in the reduced-form unemployment equation was extremely sensitive to the choice of the smoothing factor for the E/U ratio.

<sup>9</sup> The gap variable is defined as the proportional difference between actual and trend output, where the latter is estimated by applying the Hodrick-Prescott filter to GDP. To minimise possible problems in estimating trend output at the two extremes of the series (1983 and 1995), we used a longer time series from 1970 to 1998 (the latter based on the latest OECD projections). Note that the assumption of an identical parameter for the gap variable across all cross-sectional units does not significantly affect estimated coefficients for the other explanatory variables.

<sup>10</sup> The conventional F-test was used to check for unobservable, country-specific effects and when the null hypothesis was rejected at conventional significance levels, random-effects models were considered. The assumption that country-specific effects are random was tested using the Breusch-Pagan test, and Hausman's (1978) orthogonal test was used to test for the correlation between the random country-specific effects and the other regressors. Finally, the following observations were removed from the sample because the diagnostic analysis revealed that they severely affected the standard error of the regression and/or the estimated coefficients: 1983 and 1984 for Portugal; 1993, 1994, and 1995 for Finland; 1983 and 1994 for New Zealand; 1995 for Sweden and for Spain. See Scarpetta (1996) for details on the tests used to identify outliers in the data set.

<sup>11</sup> In Tables 2 and 3, the reference group includes countries with either decentralised wage bargaining, low co-ordination or a low index of centralisation/co-ordination. Thus the estimated coefficients on the other two groups refer to the performance of these systems *relative to* decentralised/uncoordinated bargaining systems. A positive coefficient implies, other things being equal, a positive effect on the unemployment rate of the bargaining system relative to the decentralised

analysis, while column 5 replicates the same specification on a sample that excludes Sweden to test for changes in the estimated parameter for active labour market policy (ALMPU).<sup>12</sup> Finally, equation 6 tests for the possible influence of statutory minimum wages on aggregate unemployment rates. Statutory minimum wages exist in only nine of the 19 countries considered in our analysis. So the coefficients for the other explanatory variables in column 6 are not necessarily comparable with those in the other columns.

There is clear evidence in Table 2 that different collective bargaining arrangements affect labour market outcomes. A high degree of co-ordination on employer and employee sides (HGCOOR) can significantly reduce structural unemployment insofar as such co-ordination provides a mechanism by which economy-wide labour market conditions can be internalised in the wage-setting process, increasing the sensitivity of real wages to shocks. There is also some evidence (see column 2) that highly centralised (HGCENTR) and fully decentralised bargaining systems lead to somewhat lower structural unemployment compared with intermediate (sectoral) systems (INTCENTR).

The summary measure of collective bargaining structures (INTCORP and HGCORP) brings together the different features of co-ordination and the bargaining levels into a single indicator. For example, the summary measure allows us to consider cases where cross-industry co-ordination between employers and unions in an industry bargaining setting (e.g., Germany and Austria and more recently, Ireland and the Netherlands, with centralised income policy agreements) may be an alternative or functionally equivalent to centralised systems.

system, and *vice versa*. In the table, the INT acronym represents *intermediate*, HG represents *high*. Appendix B discusses changes in these country groupings over time.

<sup>12</sup> Sweden has been characterised by extremely high expenditures on active labour market programmes (four times the OECD average) in the 1983-1995 period and by levels of unemployment which, albeit low (until the early 1990s), are comparable with those of countries that spent much less on ALMPs.

Notes: Each coefficient represents the expected change in the unemployment rate in response to a unitary change in the independent variable.

\* = Statistically significant at 10% level

\*\* = Statistically significant at 5% level

\*\*\* = Statistically significant at 1% level

<sup>a</sup> All regressions include a constant term, standard errors in *italic*.

<sup>b</sup> Sweden is excluded from the panel data set for this regression.

<sup>c</sup> Due to the limited number of countries in the HGCORP group in the equation 6 specification, HGCORP includes low & high centralisation/co-ordination countries.

<sup>d</sup> F-test of the hypothesis of absence of country-specific fixed effects.

<sup>e</sup> Breusch and Pagan LM test of the hypothesis of randomness of country-specific effects. The statistic is distributed as an  $\chi^2(1)$ .

<sup>f</sup> Hausman (1978) structural test, distributed as an  $\chi^2$ .

The estimated coefficients for the measures of centralisation/co-ordination (decentralised countries are the reference group) give some support to the hump-shaped hypothesis (Calmfors and Driffill, 1988), whereby highly centralised/co-ordinated systems and fully decentralised systems help to restrain the insiders' wage claims and thereby serve to lower structural unemployment.

It is also interesting to note that union density (UDENS), per se, does not help to explain cross-country differences in structural unemployment, once other features of the collective bargaining system are considered. Moreover, the empirical analysis did not detect a statistically significant impact of statutory minimum wages (relative to the average wage) on aggregate unemployment.<sup>13</sup>

Turning to the role of labour market policies, there is strong evidence that more generous unemployment benefits (UB) lead to higher structural unemployment. The implicit average elasticity of unemployment with respect to the OECD summary measure of benefit entitlements is around 0.4, a value that is close to those often found in the microeconomic literature (Holmlund, 1998).

The econometric evidence is mixed concerning the role of active labour market policies. The results in the first four columns of Table 2 show that our measure of spending on active labour market policies always has a negative coefficient; however, it is only marginally significant. But as Scarpetta (1996) has demonstrated, the presence of Sweden in the panel is crucial for this inconclusive result: if Sweden is excluded on the grounds that it is an outlier in the panel data set, the magnitude and statistical significance of the estimated coefficient for ALMPU increases sharply (the estimated coefficient becomes -0.53 in equation 5 in Table 2).

For employment-protection legislation (EPL), our results point to a positive impact of strict regulations on firing on structural unemployment. These results are somewhat more robust than those previously found by Scarpetta (1996). A possible explanation for this is that the measure of EPL used in Table 2 accounts for recent changes in regulations.

Finally, the tax wedge (TWEDGE) is statistically significant in all equations. The estimated elasticity of unemployment with respect to the tax wedge is moderate (around 0.5), which implies that the ob-

<sup>13</sup> But econometric analysis for the same panel of nine OECD countries, reported in OECD (1998b), shows that high levels of the minimum relative to average earnings reduce youth employment.

served reduction in the OECD average tax wedge of 7 percentage points during the 1983-1995 period could have contributed to reduce structural unemployment by about 0.7 percentage points.

It is of interest to compare our results with those of Layard and Nickell (1997) for 20 OECD countries based on two cross-sections for 1983-88 and 1989-94. The first point to note is that there is quite a high concordance between the two sets of results regarding the determinants of unemployment rates across OECD countries. Both studies assign significant roles to unemployment benefits, collective bargaining structures, active labour market policies (allowing for the caveat about the exclusion of Sweden), and the tax wedge—even if the variables in question are defined somewhat differently between the two studies. There are also some notable differences. For example, Layard and Nickell (1997) do not find a significant effect from EPL on the total unemployment rate. Their equation also includes the owner-occupier rate that is not included in our regressions, and they use changes in inflation to account for cyclical fluctuations of the unemployment rate, while we use the output gap.

## **2.2. Structural unemployment and reforms in the successful countries**

How do these results help to explain the role of labour market and institutional reforms on the estimated changes in structural unemployment? To answer this question we do not use the NAWRU estimates in Table 1. Instead, we proxy structural unemployment by adjusting the actual unemployment rate by the estimated cyclical component based on the coefficients of the output gap in Table 2. Then, Table 3 breaks down the estimated changes in structural unemployment into the contributions of the main determinants, namely changes in unemployment benefits, the tax wedge, and institutional settings (i.e., the joint impact of collective bargaining systems and EPL) plus a residual that accounts for changes in unobserved country-specific factors.<sup>14</sup> For each country, the estimated parameters of equation 4 in Table 2 were used to compute the expected changes in unemployment that result from the observed changes in each of the explanatory variables. The calculations were made for two time peri-

<sup>14</sup> A positive value of the country-specific effect means that other (omitted) factors have contributed to raise structural unemployment, while a negative value suggests that omitted factors have contributed to reduce structural unemployment.

ods, the full 1983-1995 sample period and the 1990-95 sub-period. In Ireland, the Netherlands, and the UK—which began introducing reforms in the early to mid-1980s—structural unemployment fell over the entire period covered in the empirical analysis (Table 3a.). In New Zealand, Australia, and Denmark, where most reforms were introduced somewhat later, falls in structural unemployment were recorded in the 1990s. For the latter countries, the decomposition over the 1990-95 period (Table 3b) is more meaningful.

An important fraction of the estimated change in structural unemployment cannot be accounted for by changes in the explanatory variables included in our analysis. Other omitted factors probably played important roles. And possible interactions between labour market policies and institutional factors, albeit difficult to identify (see below), have not been considered in the decomposition of Table 3. Bearing these caveats in mind, we can see that reforms in the key policy areas in the six *success* countries have generally gone in the direction of reducing structural unemployment, although there are noticeable differences between them in the contribution that can be assigned to each of the policies and institutional reforms.

To draw some lessons from the success stories, it is of interest to specify in somewhat greater detail what policy reforms were undertaken in these countries. Evidently, policy settings in many areas, including importantly product markets, have the scope to affect labour market outcomes, but the focus here is restricted to policies that impinge directly on labour markets.

During the past 15 years, while several OECD countries have increased the generosity of *unemployment benefits* by altering one or other of the central parameters of the system (i.e., replacement rates and duration of benefits), five of the six success countries either kept them unchanged or curtailed them.<sup>15</sup> As an illustration, in countries

<sup>15</sup> Australia is the exception. For Denmark, the OECD summary measure does not pick up the fact that the abolition in 1993 of the possibility of renewing benefit eligibility through participation in ALMPs effectively implied a cut in maximum duration, which has been followed by further cuts and recently, by a combined cut in duration and the replacement rate for young workers. For Ireland, the abolition of the earnings-related benefit in 1995 implied a significant cut in replacement rates. In the UK, the recent introduction of the Job-Seekers Allowance implied a halving in the duration of unemployment insurance benefits to six months. The Netherlands reduced the maximum duration of benefits (from 2.5 years to 1.5 years), and benefits were not raised in line with increases in earnings. In New

such as Ireland, New Zealand, and the Netherlands, the estimated impact of changes in benefits during the 1990s on structural unemployment is in the order of 0.2 to 0.6 percentage points. Moreover, the six countries (like several others) tightened up on various aspects of eligibility and job-availability conditions for receipt of unemployment benefits that are not accounted for in the OECD summary measure of benefit generosity.<sup>16</sup>

*Notes:*

<sup>a</sup> Structural unemployment is proxied by actual unemployment minus the cyclical component estimated from the coefficient of the output gap in col. 4 of Table 2.

<sup>b</sup> The degree of centralisation/co-ordination and the index of employment protection legislation (EPL).

Measured relative to GDP, spending on *active labour market programmes* shows large variations across the six countries. But three of them, Denmark, Ireland (in the 1990s), and the Netherlands, are well above average regarding spending on active policies. These countries also managed to shift more of their spending on labour market policies toward active policies and away from unemployment benefits during the 1985-97 period. In Australia, New Zealand, and the UK, there has also been a shift in the orientation of spending on active policies toward job-search assistance and counselling for groups with particular disadvantages in the labour market. In Denmark, this shift in emphasis was a key element of the 1994 labour market policy re-

form, which laid down that individual action plans must be prepared for all people with more than three months of unemployment.

The overall *tax wedge on labour use* has been reduced in several OECD countries over the past decade, including the six success stories. The tax burden was reduced by more than 5 percentage points in the UK, Ireland and New Zealand, and by almost 8 percentage points in the Netherlands (albeit from an extremely high level in the early 1980s). According to our econometric estimates, these reductions could have lowered structural unemployment by about 0.2 to 0.5 percentage points. Australia recorded a decline in the tax wedge in the late 1980s that was subsequently reversed.

Because of their direct effect on labour costs, employer social security contributions were cut in recent years in several countries, sometimes targeted to encourage the hiring of low-wage workers. Thus, the Netherlands, Ireland, and to a minor extent the UK, reduced these contributions together with France and Sweden. But in the latter two countries, the tight fiscal position meant that other taxes had to be raised to offset the revenue loss.

Though there are marked differences in the strictness of EPL across OECD countries, there has been a tendency toward less constraining hiring and firing practices in several of them, including some of the six success cases. In particular, there has been some relaxation of EPL in the case of individual and/or collective dismissals in the UK (1993), and in Italy (1991), Portugal (1989, 1991), Spain and, more recently, in Germany and the Netherlands. In Australia, in response to employers' concerns about the 1993 tightening of regulations, new legislation was introduced in 1994 and 1995 to reduce legal costs to employers and to simplify procedures for dismissal in justified circumstances. But France moved in the opposite direction, with some easing of dismissal procedures (abolition of the administrative authorisations) in 1986 being followed by tightening in 1989 and 1993 for collective redundancies (the introduction of social plans).

As previously stressed, there are several relevant dimensions to *wage formation* that make it difficult to characterise a country as having done better or worse over time in this field. In addition, many aspects of wage formation are only indirectly amenable to policy influence, resting principally on private-sector decisions. Notwithstanding these difficulties, the six countries seem to have moved away from uncoordinated, sectoral, wage bargaining to either higher co-ordination or full decentralisation, both leading to greater wage mod-

eration and lower structural unemployment, at least according to our empirical results (see Table 3). Widespread decentralisation of wage bargaining has been the result of a deliberate policy aimed at reducing union power in the UK and New Zealand. Wage bargaining has also been substantially decentralised in Denmark, though employers maintain a significant element of co-ordination, and Australia has also moved toward decentralisation since the late 1980s, if from a very particular starting point. By contrast, Ireland (since 1988) and the Netherlands (since 1983) have conducted wage bargaining with close co-ordination among the government, employers' associations, and trade unions.

At the end of the day, what appears to set apart the six success stories from those countries that have failed to prevent a rise in structural unemployment in the 1990s is that they have implemented policy reforms across most of the key policy areas identified in the empirical analysis. Indeed, the six countries stand out as a group more in terms of the *comprehensive* coverage of reforms than in terms of their having taken particularly bold steps in specific areas—with industrial relations reform in New Zealand and to some extent in the UK, standing out as exceptions. To this comprehensive approach must be added the effects of relatively successful macroeconomic policies (see below).

Comprehensiveness seems indeed to be a crucial feature of any successful strategy to reduce unemployment because reforms in different areas can reinforce each other's effects. Conversely, policies that tend to drive up unemployment may also be mutually reinforcing. An example is that an increase in payroll taxes may have a larger effect on unemployment if introduced in a context of a high minimum wage, which prevents backward shifting of the tax hike into wages.<sup>17</sup>

### **2.3. Are there significant interactions between labour market policies and institutions?**

Labour market policies may have a different impact on the functioning of the labour market depending upon the institutional framework within which they operate. Interaction mechanisms are generally

<sup>17</sup> Such interaction effects have recently received theoretical backing in Coe and Snower (1997). At the practical level, the OECD's reviews of individual countries' progress in implementing the *Jobs Strategy* have thrown up many examples of such interactions between policies in different fields—for details, see OECD (1997b).

complex and may not be fully accounted for by the analytical approach used in this study. But to shed some preliminary light on this issue, Table 4 presents the results of reduced-form unemployment rate regressions in which some policy parameters are allowed to vary across different policy and institutional settings. The results reported refer to those interactions that were statistically significant.

Column 1 in Table 4 suggests that unemployment benefits probably have different effects on structural unemployment depending on the intensity of public spending on active labour market policies. In countries that spend a lot on active programmes, per person unemployed, unemployment benefits have a slightly stronger impact than they do in the intermediate group of countries.<sup>18</sup> This result has intuitive appeal: the joint effect of generous benefits and high spending on active programmes serves to raise the reservation wage of the unemployed over and above what each policy in isolation would have done and thus leads to an even stronger aggregate impact on unemployment. But given this reasoning, one would expect to find the largest interaction effect for the countries with the highest spending on ALMPs, followed by the group of intermediate and low-spending countries in that order. The fact that our estimates do not match this pattern is a finding for which we have no satisfactory explanation.

Buti et al. (1998) argued that strict EPL may act as a substitute for unemployment insurance benefits. Under this hypothesis, countries might opt for either generous unemployment benefits and lax EPL or *vice versa*, and a combination of generous benefits with strict EPL could lead to higher structural unemployment. But the evidence in column 2 of Table 4 does not support this hypothesis: the estimated effect of unemployment benefits is not statistically different in countries with either strict or lax EPL.

Table 4 suggests that different collective bargaining arrangements influence the way in which EPL and the tax wedge affect unemployment. In both cases, the positive impact on aggregate unemployment is stronger and statistically significant in countries with an intermediate degree of centralisation/co-ordination, i.e., where sectoral wage bargaining predominates with limited co-ordination, while neither EPL nor the tax wedge are statistically significant in either highly

<sup>18</sup> The Wald test rejects the restriction that the coefficients of UB are equal for the three groups of countries according to their spending on ALMPs.

centralised/co-ordinated or decentralised countries.<sup>19</sup> These results are consistent with the hypothesis that when insiders have strong bargaining power, they may more easily resist employers' attempts to reflect higher payroll taxes and/or high turnover costs (due to strict EPL) in lower wages, even if this works to the detriment of outsiders.

Bearing in mind the tentative nature of these results, they may have some implications for the understanding of the determinants of changes in structural unemployment discussed above. In particular, the impact of significant changes in the tax wedge may have been less marked in countries with either a high degree of centralisation/co-ordination (i.e., Austria and Germany) or decentralised wage bargaining systems (i.e., Canada and Japan). Conversely, the impact could have been stronger in countries with intermediate wage bargaining settings (e.g., Belgium, Finland, France, and Spain). Similarly, the tightening of EPL in France in 1989 and 1993 might have produced a more important increase in structural unemployment than that calculated in Table 3, while the loosening of EPL in Portugal in the 1990s might have contributed more strongly to the estimated reduction in structural unemployment.

#### 2.4. The role of macroeconomic policies

Sound macroeconomic policies are an important element in any comprehensive strategy to combat high and persistent unemployment. This is in part because large macroeconomic fluctuations are likely to contribute to rising structural unemployment as increases in unemployment, which are initially cyclical, tend, over time, to become structural.<sup>20</sup>

<sup>19</sup> Daveri and Tabellini (1997) obtained a similar result for the differentiated impact of the tax wedge on unemployment, although they included a smaller number of countries in their analysis and used a slightly different classification of countries according to the collective bargaining system.

<sup>20</sup> This would also occur if the impact of unemployment on wage inflation is non-linear (the Phillips curve). For example, if the difference between the log of unemployment and the log of the natural rate drives changes in inflation, the average level of unemployment will be larger, the greater the variance of unemployment, even if the log of unemployment is on average equal to the log of the natural rate. Indeed, if  $(\log U - \log U^*)$  is normally distributed with mean zero and variance  $\sigma^2$ , then the expected value of  $U$  is:  $E(U) = \exp(\log U^* + \frac{1}{2}\sigma^2)$ . Turner (1995) presents estimation results that suggest that, for three of the G7 countries, the inflationary effects of a positive output gap (output being above trend) are much bigger than the disinflationary effects of a corresponding negative output gap.

INTCORP the list of countries in each group and changes over time, see Table  
LWCORP B2.

<sup>a</sup> Sweden is not included in the sample.

Across countries, a positive correlation exists between the degree of annual volatility of unemployment and the extent of the rise over time in structural unemployment (Figure 2). Thus, stable conditions may help to maintain low structural unemployment. As a corollary, countries with macroeconomic room for manoeuvre to counteract prolonged slumps in macroeconomic conditions (e.g., Norway) have often avoided strong increases in actual unemployment.

**Figure 2. Cyclical variability and structural unemployment,<sup>a</sup> 1985-97 (percentage points)**

Notes:

<sup>a</sup> Structural unemployment data are based on estimates of the NAWRU made for the OECD *Economic Outlook*, 63, 1998.

<sup>b</sup> Measured by the standard deviation of yearly changes in unemployment rates.

Source: OECD.

There are also potentially important interactions between macroeconomic and structural policy settings. Thus labour market policies can help determine to what extent cyclical unemployment increases

are translated into higher structural unemployment.<sup>21</sup> The policy implications of this include:

- For countries with very rigid labour markets, macroeconomic instability carries a particularly high price in terms of structural unemployment, whereas countries with flexible labour markets, most notably the US, have experienced large cyclical fluctuations in unemployment around a rather stable level of structural unemployment.<sup>22</sup>
- Moves toward medium-term macroeconomic targets will often be less costly in terms of unemployment if the appropriate structural policies have been implemented first (Ball, 1996). Conversely, a sequencing that involves moving toward macroeconomic targets before implementing structural reform may be expensive in terms of unemployment.

The medium-term orientation of macroeconomic policies will probably also be important. This is mainly due to the effects over the longer term of sound public finances and price stability on unemployment *via* the channel of real interest rates:

- A fall of real interest rates may lower production costs in much the same way that lower payroll taxes or energy prices would do, and it may raise capital accumulation and thereby labour productivity. Where wage earners do not receive a corresponding increase in real wages, unemployment might fall.
- In some cases, lower real interest rates may affect the bargaining attitudes of workers and the labour-demand behaviour of enterprises, leading to the end result of lower unemployment.<sup>23</sup>

<sup>21</sup> Scarpetta (1996) links slow adjustment of unemployment to strict employment protection, generous unemployment benefits, and aspects of wage bargaining systems. Layard (1989) finds that long benefit durations slow adjustment whereas centralised bargaining and expenditure on active labour market policies speed it up.

<sup>22</sup> Bean (1997) provides some empirical evidence of the long-lasting effect of a demand shock in EU countries compared with the US.

<sup>23</sup> Phelps (1992) argues that real interest rates affect the value that firms put on their customer base and their stock of employees familiarised with the firm, and thereby labour demand. Similarly, in a context where current employment raises the chances of future employment, a lower real interest rate may soften the bargaining stance of wage earners because the discounted value of future earnings associated with having a current job will increase.

- Lower real interest rates could also favourably affect productivity growth, either temporarily—while the capital-intensity of production responds, or more long lastingly—if the rate of innovation and its diffusion are affected. Increased productivity growth again might cause unemployment to fall. This would be the case to the extent it reduced the incidence of downward wage stickiness or facilitated wage bargaining by increasing the scope for real-wage gains.<sup>24</sup>

Empirical estimates of the effects of real interest rates on cross-country differences in unemployment yielded results that are variable but suggestive of significant impacts in some countries.<sup>25</sup>

### 3. Overcoming resistance to labour market reform

The analysis in the previous section treats a range of institutional and labour market policies as exogenous factors. On this view, unemployment is basically the result of misguided policies. But an alternative view sees the policy settings that influence unemployment as determined by political-economy considerations. This may also explain why it is so difficult to introduce policy reforms that will reduce unemployment. This section discusses the role that resistance by labour market insiders may have played as a hindrance to effective labour market reform; the role of equity considerations in shaping policies; and some evidence on the role of crises in overcoming resistance to reforms.

#### 3.1 Insider resistance as a hindrance to reform

There can be little doubt that the insider-outsider distinction is an important one. Figure 3 shows a cross-country breakdown of em-

<sup>24</sup> Manning (1992) argues that higher productivity and real-wage growth increase the incentives to set wages so that a job is retained.

<sup>25</sup> Scarpetta (1996) finds that the rise in real interest rates accounted for between 1 and 3 percentage points of the rise in the unemployment rate across 17 OECD countries during the 1971-93 period. Manning (1992), in a study of 19 OECD countries, finds effects suggesting that a 1 percentage point increase in real interest rates may increase unemployment by between 0 and 1 percentage point. In a study of 17 OECD countries, Phelps (1994) finds an impact of 0.1 to 0.4 percentage points on unemployment. Cotis et al. (1996) report estimates suggesting that rising real interest rates accounted for about half of the rise in the French equilibrium unemployment rate between 1974 and the mid-1990s.

ployment rates by age and gender. What sets countries apart in terms of overall employment/population rates is largely the extent to which *outsider* groups are employed. The young, older workers, and adult women represent outsiders in Figure 3. By contrast, the employment/population rates of prime-age males, a group dominated by *insiders* are much more similar across countries.

Arguments why insiders may oppose reforms that would produce higher employment for outsiders come in different forms. One such argument is that insiders are virtually unaffected by the unemployment consequences of labour market rigidities, but that the same rigidities may enhance their bargaining power in wage negotiations.

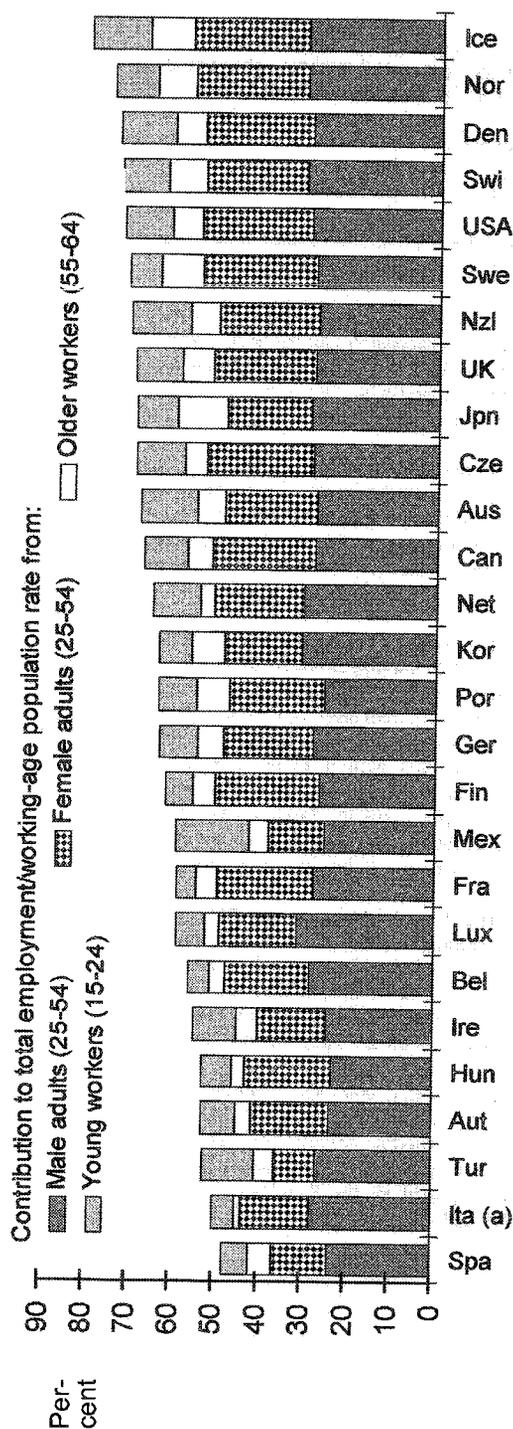

In these circumstances, insiders will have an interest in raising rigidities to the point where the extra gain in terms of higher real wages is offset by the loss in terms of added risk of unemployment and related income loss.<sup>26</sup>

Some empirical observations are consistent with such an insider-outsider view of policy determination:

- Across countries, there is a positive correlation between strictness of EPL for permanent workers and *excess coverage of wage contracts*, which is a measure of the extent to which union wage agreements are extended to non-union members (Figure 4). This suggests that the insiders, who benefit from strict EPL, may press for administrative extension of wage agreements as a protection against underbidding of their wages by outsiders.
- Spending on active labour market policies should empower labour market outsiders to compete more effectively with insiders. It may be no coincidence that Figure 5 shows a positive correlation between the extent of such spending (per unemployed and relative to per capita GDP) and the extent of union density. Where large parts of the labour market (including those with an outsider or near-outsider status) are organised, there may be greater internalisation of the gains from integrating outsiders and greater pressure to do so.

<sup>26</sup> Seeing policy settings as endogenously determined has potential implications for the Section 2 analysis. In principle, it could raise questions about the direction of causality of the links between unemployment and policy settings and about the extent to which coefficients in Table 2 may be biased as estimates of the impact of policy settings on unemployment. To spotlight this issue, we ran some Granger causality tests to explore the possibility of reverse causality (see Appendix B). The results mostly tend to support interpretations of the empirical results in Section 2.

**Figure 3. Decomposition of the employment rate, 1996**

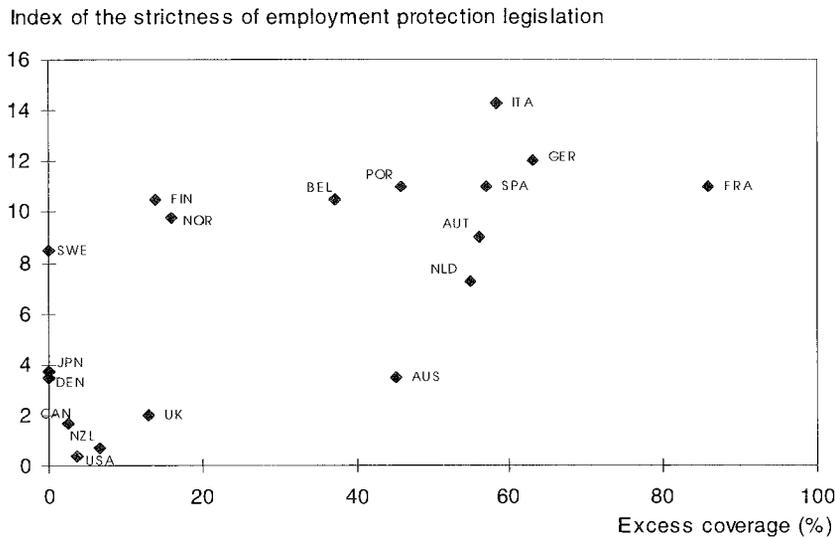

Notes:

<sup>a</sup> Italy 1997. Adults = 25-59 years of age.

The contributions of individual demographic groups to the overall employment/working-age population rate were calculated as the group-specific employment rates multiplied by the share of individual groups in the population of working age. The countries are ordered from left to right in ascending order of the total employment population rate.

Source: OECD Labour Force Statistics, Analytical Data Base.

**Figure 4. Employment protection legislation and coverage of wage agreements**

*Note.* The excess coverage index is the difference between the coverage rate (proportion of workers covered by the terms of wage agreements) and union density rate.

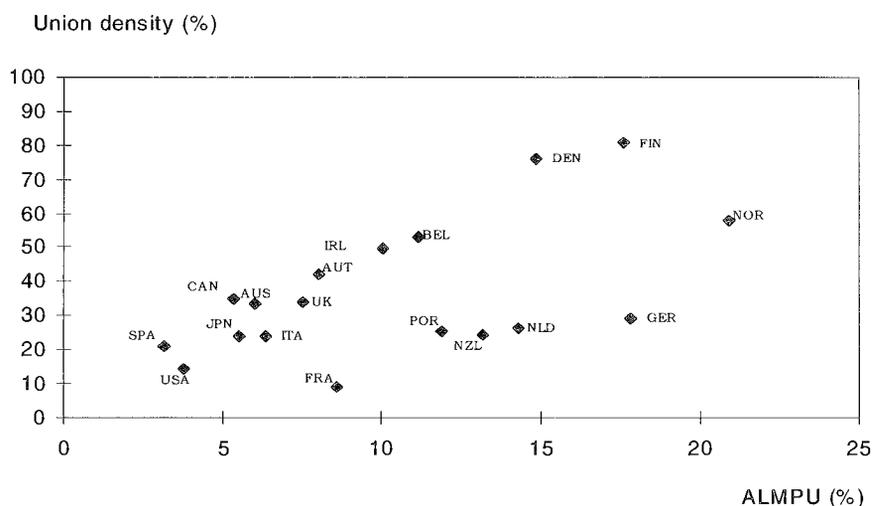

Evidence in OECD (1997b, 1998a) suggests that successful countries may have succeeded where others failed, in part, because their reform efforts to a greater extent were directed at reducing the bargaining power of insiders:

- Many countries have tightened up the eligibility conditions of their unemployment benefit schemes—a move that is unlikely to affect the insiders who, by definition, enjoy high job tenure. By contrast, central parameters of unemployment and related welfare benefit systems such as replacement rates and duration of benefits, which may affect the bargaining positions of insiders, were left relatively untouched in most countries outside the group of success stories.
- In a similar vein, many countries have eased up on the regulation of fixed-term contracts that expanded the supply of temporary jobs for outsiders, but it has typically been much more difficult to lower employment protection for permanent workers. In this context, Bentolila and Dolado (1994) argue that the existence of a group of temporary workers, who are easy to lay off, effectively

reduces the unemployment risk of the secure insiders, and thus strengthens their position in wage bargaining.

This raises the question why successful countries could introduce policy reforms that affected insiders whereas other countries could not. Initial weakening of insider power may be part of the answer.

**Figure 5. Union density and active labour market programmes**

*Note.* ALMPU is spending on active labour market programmes per unemployed relative to GDP per capita.

Thus in some of the successful countries, in particular the UK and New Zealand, governments took determined action at the outset of the reform process to weaken the bargaining power of insiders, notably through curbs on union rights and privileges. In other success countries, including Ireland, the Netherlands and Australia (at least in the initial phase of reform in the 1980s), there were moves toward increased centralisation of wage bargaining and a more corporatist attitude toward the setting of labour market policies, which may have led to a greater internalisation of outsider interests. But these are only proximate answers, because they do not explain why the weakening of insider power occurred in the first place.

In some cases, insider resistance may also have been reduced because individual reforms were seen as part of a comprehensive strategy of structural reforms. The argument would be that any individual

reform might hurt the insiders who will therefore resist it. But when individual reforms are part of a much wider strategy, affecting all groups, they may be seen as more fair, the losses suffered by any particular group may not appear excessive, and there may be a stronger likelihood of economy-wide gains that may compensate some of the losses.

### 3.2. Equity concerns as a hindrance to reform

A reason often cited by countries to account for slow and sporadic implementation of the *OECD Jobs Strategy* recommendations is the perception that undertaking reform of, in particular, wage formation, EPL and social transfer systems involves conflict with policy objectives concerning income distribution.

Reflecting the many complicated mechanisms operating in this area, OECD research as to the nature and magnitudes of any potential trade-offs has provided no conclusive evidence. Nevertheless, it has been suggested that equity and efficiency objectives do not necessarily conflict, or at least that the terms of the trade-off may change, when they are seen in a dynamic perspective. Three reasons have been quoted for this:

1. Increased employment, because of policy reform, will tend to offset, at least partly, the impact of increased wage dispersion and restricted social transfers on income distribution. Thus, a wider distribution of wage rates is likely to enhance the employment prospects of workers at the bottom of the qualifications scale. But little agreement exists about the magnitude of such employment effects, with econometric estimates of elasticities between relative wage rates and demands for different categories of labour being highly uncertain and variable across studies.<sup>27</sup>
2. There is evidence of considerable mobility of individuals over time within the earnings distribution, showing that in some cases low-paid jobs are a stepping-stone to good careers. Across countries, with large differences in the static distribution of earnings,

<sup>27</sup> For example, estimates of elasticities of substitution between different categories of labour substantially above one were found by Bound and Johnson (1992) and Katz and Murphy (1992) for the US, and by Risager (1992) for Denmark. In contrast, Machin et al. (1996) find an elasticity of around one for the US and less than one-half for the UK, Denmark and Sweden.

the degree of mobility seems remarkably similar.<sup>28</sup> OECD (1997c, Chapter 2) shows that, as a rule of thumb, after a period of five years only about one-third of those full-time workers initially receiving low earnings (belonging to the lowest earnings quintile) do so at the end of the period. A large part of the workers who left low-paid employment had moved up in the earnings distribution, though in some countries a significant fraction had also moved out of employment (in particular, this was the case in the US).

3. Lower relative incomes at the bottom of the scale may raise incentives for investment in human capital by groups who would otherwise have made little such investment; the existence of this kind of linkage is supported by evidence that, across countries, university graduation rates tend to be higher where the financial reward to such education is higher (Figure 6).<sup>29</sup> Such an effect, in turn, could reduce income dispersion over the longer run and assist the adaptation of the workforce to changing skills requirements.

Nevertheless, there are also arguments that might suggest that the equity-efficiency trade-off is even starker. For example, there is concern about the effectiveness of relative wage signals in influencing human-capital investment, not least because increased inequality of income, in a context of imperfect capital markets, may prevent those at the bottom of the income distribution from investing in their own or their children's education.<sup>30</sup>

In the context of the conflicting evidence on the strength, and perhaps even the sign, of the equity-efficiency trade-off, the Nordic countries have tended to take a strong position against wider dispersion of wage rates as a means of reducing unemployment. Instead, policies are directed toward validating the existing, relatively compressed earnings distributions in these countries by creating a similarly narrow distribution of individual productivities. The emphasis is

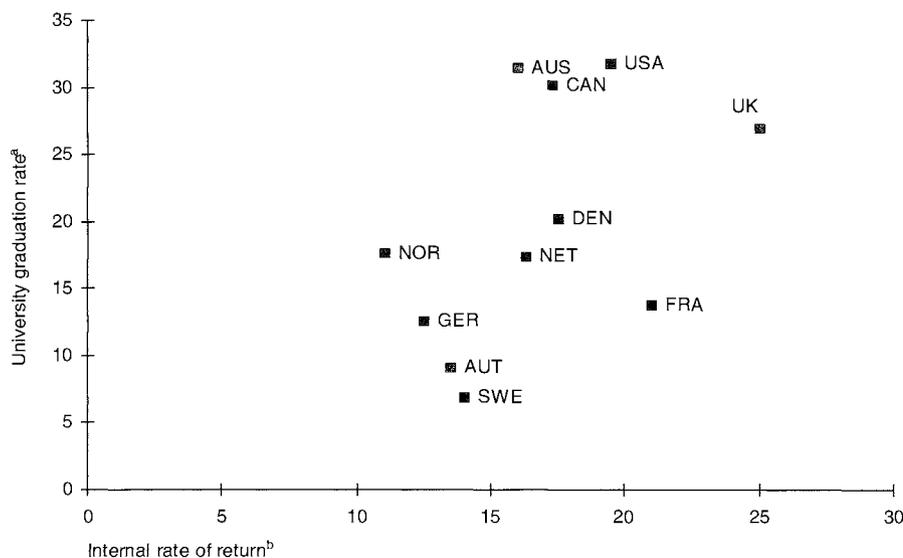

<sup>28</sup> This is based on the comparative data on earnings mobility in several countries presented in OECD (1996c, 1997c). Aaberge et al. (1996) also supported the finding of broadly similar mobility patterns across countries.

<sup>29</sup> The rates of return in Figure 6 do not account for the effects of tax-transfer systems, including support for students or different unemployment risks across education categories.

<sup>30</sup> Benabou (1996) presents a model that illustrates this point.

put, in particular, on education and active labour market policies to achieve this latter goal. But beyond a certain level of spending, active labour market policies may suffer from declining returns to scale. Even abstracting from this consideration, the results in Section 2 suggest that quite sizeable public spending in this area, with accompanying effects on taxes, could be required to validate relatively compressed earnings distributions. Moreover, there is a question as to how effective government subsidies to education, through near-free provision and generous grants, can be as an instrument to offset the disincentives arising from compressed wages and progressive taxes.

**Figure 6. Internal rate of return and university graduation rates**

### 3.3. The role of crises in facilitating reform

OECD (1988) argued that crisis conditions are often necessary to change the general orientation of macroeconomic policies. In a similar vein, crises may help to overcome resistance to labour market reforms, be it based on insider intransigence or equity considerations. Indeed, it has been argued that many of the successful countries embarked on reform programmes because "existing policies could no longer be sustained" (OECD, 1997b).

Taking a more systematic view on the role of crises should begin with an attempt to date the beginning of the reform process. For the six successful countries, this produces the following picture:

- In Australia, the re-orientation of policies has been a gradual process, beginning with trade liberalisation and tri-partite wage Accords after the new Labour government took office in 1983. This process gathered speed in the late 1980s and early 1990s with moves toward decentralisation of wage bargaining and an increasingly medium-term orientation of macroeconomic policies.
- In Denmark, the 1982 change of government marks a relatively clear break, with an immediate shift toward a medium-term orientation for macroeconomic policies, based on a fixed exchange rate vis-à-vis the DM and fiscal consolidation, and the abolition of indexation of private and public-sector wages and income transfers.
- For Ireland, the shift in policy stance also dates back to the early 1980s when the incoming coalition government embarked on a major shift in the orientation of fiscal policies, emphasising the imperative need to halt the debt spiral. The 1987 change in government led to a strong focus on wage moderation achieved through tri-partite national agreements, and with a tax-based element as government finances improved. The 1990s have seen sustained attempts to raise work incentives via reforms to the tax/benefit system, cuts in the tax wedge, and increased spending on ALMPs.
- In the Netherlands, 1982 is also a watershed year, with a change of government, a shift toward fiscal consolidation (eventually to be followed by tax cuts) and deregulation, and the conclusion of the tri-partite so-called Wassenaar agreement on wage moderation.
- In New Zealand, the change of government in 1984 marks a clear shift in economic philosophy toward one of stability-oriented macroeconomic policies and market deregulation—a series of re-

forms to the collective bargaining system culminated in the Employment Contracts Act in 1991.

- In the UK, the change in government that occurred in 1979 also led to increased emphasis on market deregulation and macroeconomic stability—even if the latter proved to be rather elusive, at least until recently.

One notable lesson from this dating exercise is the role that changes in government seem to have played in the context of radical shifts in policy orientation. Not surprisingly, it is easier for a new government to break with past policies and strike out on a new path. A second lesson is that it can take a long time for a radical shift in policy orientation to bear fruits in terms of making significant inroads into structural unemployment. In most cases, the reform process in the successful countries got underway in the early or mid-1980s, but it took up to a decade before this was translated into success.

Even if a change of government was involved at the start of the reform process in the success countries, this does not explain why shifts in government in other countries did not lead to sustained reforms capable of reducing structural unemployment. We tried to examine whether particular features of economic developments might explain why reform programmes were enacted. The main results are:

- Major hikes in unemployment occurred in the years before the beginning of the reform process in Australia, Denmark, Ireland, and the Netherlands (Table 5). But for the other two success countries, it is difficult to argue that a sharp rise in unemployment was a major trigger of reform. And, some other countries experienced periods of significant rises in unemployment without embarking on sustained reforms. In other cases, though, sharp hikes in unemployment may have prompted a change in policy orientation that has not yet had sufficient time to work.
- A misery index, constructed by summing unemployment rates, government budget deficits, and external deficits relative to GDP, is not suggestive of crisis as a major common factor among the six countries. Denmark and Ireland are the only countries with a sharp rise in the misery index just before reform; Australia and the Netherlands had recorded a steady, but fairly slow, rise in the index; and, if anything, the index had tended to decline in the UK. Several other countries also recorded increases in the misery index that match those of the successful countries.

- Exchange-rate pressures are capable of precipitating or exacerbating crises, and they were strong at the time of policy change in Denmark, Ireland, and New Zealand. Moreover, while pressures may not have been as strong, the Netherlands actually devalued in 1982, and the UK exchange rate declined significantly through 1978 and into 1979 (the winter of discontent). But Australia did not really experience exchange-rate pressures before 1986, that is, after the reform programme had been launched.

**Table 5. Unemployment developments and policy reform 1961-96<sup>a</sup>**

Country <sup>b</sup>	Change in unemployment preceding policy reform		Maximum rise in unemployment over <sup>c</sup>	
	2 years	3 years	2 years	3 years
Australia (1983)	4.2	3.9	4.2 (83)	4.6 (92)
Denmark (1982)	2.8	3.6	4.5 (75)	4.5 (76)
Ireland (1982)	4.0	4.1	4.0 (84)	6.5 (83)
Netherlands (1982)	4.5	4.9	5.2 (83)	7.0 (83)
New Zealand (1984)	0.9	1.1	3.2 (91)	4.7 (91)
UK (1979)	-0.6	-0.3	4.5 (81)	5.9 (82)
US			3.6 (75)	3.9 (82)
Japan			0.7 (94)	1.0 (95)
Germany			3.4 (83)	4.7 (83)
France			2.3 (93)	2.8 (94)
Italy			2.5 (94)	3.1 (95)
Canada			4.3 (83)	4.4 (83)
Austria			1.8 (83)	2.2 (83)
Belgium			4.0 (82)	5.3 (83)
Finland			10.2 (93)	14.4 (93)
Greece			3.8 (83)	5.1 (83)
Iceland			2.9 (93)	3.3 (94)
Norway			2.8 (89)	3.1 (90)
Portugal			3.8 (76)	5.2 (77)
Spain			6.4 (93)	7.9 (94)
Sweden			5.3 (93)	6.6 (93)
Switzerland			3.4 (93)	4.0 (93)

Notes:

<sup>a</sup> Data availability restricts the period for some countries.

<sup>b</sup> Year when policy reform began in parentheses.

<sup>c</sup> End-year of rise in parentheses.

Overall, it is difficult to argue that the existence of a crisis, in the narrow sense of a sharp rise in unemployment, or in the misery index or in exchange-market pressures, was a common factor triggering policy reform in the success countries and setting them apart from other countries. Clearly, other countries went through crises without introducing policies sufficient to reduce structural unemployment. But the success countries generally began their policy reforms against a background of either full-blown crisis or, at least, critical developments. In sum, while the evidence is not very conclusive, it might tentatively be argued that crises tend to create a groundswell of support for reforms, though the ability to harness such support and translate it into actions depends on political factors, such as shifts in government.

#### 4. Concluding remarks

Recent OECD work on remedies for the unemployment problem has highlighted an important message: countries can reduce high and persistent unemployment significantly if they implement the right policies in a determined fashion.

This message is important because it runs counter to the sense of pessimism about tackling the unemployment problem that pervades much of the debate in the media and general public in many OECD countries today, especially in Europe. Hence, there is nothing inevitable about high unemployment, even if the evidence suggests that it can take quite some time for a successful strategy to bear its fruits.

It is also important to add that the six country successes highlighted by recent OECD research span a wide range of social, economic, and political models that include four EU countries.

When one reviews the experiences of the country successes and failures, one is struck by the great diversity in their experiences. There is no unique golden road to implement the policies required for success.

This paper identifies several policy settings and institutional features of the labour market that are associated with high structural unemployment. At the same time, it tries to highlight some important common features across those countries that were successful in reducing structural unemployment. In particular, we emphasise the importance of opting for a *comprehensive* set of reforms to all the policies and institutional factors that are the main determinants of structural unemployment, and to exploiting the synergies between these re-

forms and macroeconomic policies. We also draw attention to the important role played by changes of government, often against the backdrop of crises, in implementing effective reforms.

We also discuss some of the obstacles to implementation of the OECD *Jobs Strategy*. Some of the medicine prescribed under the OECD recommendations is bitter and hard for many countries to swallow, especially insofar as it appears to raise concerns about equity and appears to threaten some of the rents and privileges of insiders. As a result, there is natural tendency in many countries to delay needed reforms in certain areas and/or to search for alternative, sweeter remedies.

It requires strong political will and leadership to convince electorates that it is necessary to swallow all the medicine, and that it will take time before this treatment leads to improved labour market performance and falling unemployment. But the success stories show that it can be done.

## Appendix A. OECD indicator of structural unemployment

The OECD indicator of structural unemployment is based on the notion of a non-accelerating wage rate of unemployment, *NAWRU*. Estimates are derived under the assumption that changes in wage inflation are proportional to the gap between actual unemployment and the *NAWRU*:

$$D^2 \log W = -a \cdot (U - \text{NAWRU}), a > 0, \quad (\text{A1})$$

where  $D$  is the first-difference operator, and  $W$  and  $U$  are levels of wages and the unemployment rate, respectively. Using consecutive observations, and assuming the *NAWRU* to be constant between two consecutive years, an estimate of  $a$  can be calculated as:

$$a = -D^3 \log W / DU \quad (\text{A2})$$

which yields an estimate of the *NAWRU* as

$$\text{NAWRU} = U - ((DU / D^3 \log W) \cdot D^2 \log W). \quad (\text{A3})$$

Conceptually, the *NAWRU* estimated in this way is a short-run concept, i.e., it indicates the unemployment rate which, in a given year and based on the *actual* history of unemployment, would be associated with a constant rate of nominal wage increases.<sup>31</sup> In practice, the OECD indicator of structural unemployment takes into account not only the (suitably smoothed) mechanical estimates based on the above method but also the views of country experts (Giorno et al., 1995).

<sup>31</sup> In the presence of speed-limit effects or slow adjustment, a lower (or higher) unemployment rate may be associated with stable wage inflation in the long run, but this unemployment rate cannot be reached in the short term without setting off changes in inflation.

## Appendix B. The empirical analysis

Table B.1 shows basic characteristics of variables used in the regression analysis in Tables 2 and 4. More details are in Scarpetta (1996).

**Table B.1. Basic characteristics of the variables used**

Variables	Averages of values over the 1983-95 period				No. of countries
	Mean	Standard deviation	Minimum	Maximum	
UR	7.96	4.23	1.46	22.60	19
ALMPU	14.03	16.29	3.11	78.94	19
UB	29.77	12.92	0.35	70.97	19
EPL	6.88	4.34	0.36	14.25	19
UDENS	41.44	20.09	8.83	91.00	19
GAP	-0.29	2.50	-7.88	8.72	19
TWEDGE	38.39	9.40	17.70	54.51	19
MINWAGE	47.57	10.12	29.33	65.34	9

Acronym	Explanation
UR	For all countries but Denmark (administrative data), the OECD standardised unemployment rate.
ALMPU	Public expenditures for active labour market programmes per person unemployed relative to GDP per capita (in per cent).
UB	The OECD summary measure of benefit entitlements that is computed as the average of unemployment benefit replacement rates for two earnings levels, three family situations, and three duration categories.
EPL	Index of the strictness of employment protection legislation (see below).
UDENS	The proportion of workers who are members of a trade union (in per cent).
GAP	Output gap = $[(A_o/T_o)-1] \cdot 100$ ; where $A_o$ is actual output and $T_o$ is trend output computed by applying the Hodrick-Prescott filter to actual output.
TWEDGE	The total value of employers' and employees' social security contributions and personal income tax paid divided by gross earnings plus employers' social security contributions.
MINWAGE	Gross statutory minimum wage relative to the average wage.

### **Negotiating levels and co-ordination in collective bargaining arrangements**

The collective bargaining structure of each OECD country was assessed on the basis of the union density index (the proportion of workers who are member of a trade union) and indicators of the predominant level of wage bargaining and the level of co-ordination among employers, on the one hand, and among trade unions, on the other hand. Moreover, we also used a summary measure that considers both the degree of centralisation and the degree of co-ordination in bargaining.

Three dummies were created to capture the level of centralisation, co-ordination or the summary measure (1 = low; 2 = intermediate; 3 = high).<sup>32</sup> The reference group in the tables of the main text includes countries with low levels of centralisation and co-ordination. The summary measure of centralisation/co-ordination was computed on the basis of the values assigned to the two individual indexes, considering the degree of centralisation first, and then the degree of co-ordination. In countries with decentralised wage bargaining, it was assumed that different degrees of co-ordination did not significantly modify the potential labour market outcomes: wages were still considered to be predominantly determined by firms' conditions. But co-ordination was considered crucial in the case of intermediate (sectoral) wage bargaining: each bargaining unit could generate dis-employment effects if the decisions of employers' associations and sectoral trade unions are not well co-ordinated. Finally, high centralisation is generally accompanied by a high degree of co-ordination and countries in this group were considered as highly centralised/co-ordinated.

The distribution of countries according to the three measures and the changes over the period covered by our data are in Table B.2. It should be stressed that the indicators in Table B.2 are intended to summarise the broad trend in the degree of centralisation and/or co-ordination in each country and cannot fully account for repeated changes in a short time period, such as the zigzag path toward decentralisation observed in some Nordic countries.

<sup>32</sup> The classification proposed is based on recent OECD publications, including the 1995 and the 1997 issues of the OECD *Employment Outlook* (chapter 5 and chapter 3, respectively) and the special chapters on implementing the *Jobs Strategy* in the OECD Economic Surveys.

Table B.2. Country groupings—according to degree of ...

Country	Centralisation	Co-ordination
US	1	1
Japan	1	3
Germany	2	3
France	2	2
Italy	1; 3 since 1992	2; 3 since 1992
UK <sup>a</sup>	2; gradually to 1	1
Canada	1	1
Australia	2; 1 since 1988	2; 1 since 1988
Austria	2	3
Belgium	2	2
Denmark	3; gradually 2	3
Finland <sup>b</sup>	3; gradually to 2	2
Ireland	2	2; 3 since 1988
Netherlands	2	2; 3 since 1982
New Zealand	2; 1 since 1991	1
Norway	3	3
Portugal	2	2
Spain	2	3; 2 since 1987
Sweden	3; gradually 2	3; gradually 1 in the 1980s and back to 2 in 1991-95

*Notes:*

<sup>a</sup> In the UK, there has been a gradual move toward company-level pay setting. In the empirical analysis, it was assumed that by the end of the 1980s the UK was among the decentralised group of countries.

<sup>b</sup> In Finland, economy-wide bargaining agreements set guidelines rather than binding provisions, and sectoral unions have often, and increasingly over time, deviated from these guidelines. In the empirical analysis, it was assumed that in the second half of the 1980s, Finland was among the intermediate group of countries.

## ...centralisation/co-ordination (1=low; 2=intermediate; 3=high)

Summary measure of centralisation/co-ordination	Comments
1	
1	
3	
2	
1; 3 since 1992 2; gradually to 1	Income policy accords of July 1992 and July 1993
1	
2; 1 since 1988	Industrial Relations Act of 1988 followed by the Industrial Reform Act of 1993, that created a formal system of enterprise bargaining
3	
2	
3	Move toward decentralised bargaining but with a strong degree of co-ordination
3; gradually to 2 2; 3 since 1988	Tripartite three-year national pay agreements since 1988
2; 3 since 1982	Wassenaar Agreement, 1982, which set tripartite negotiations at national level on pay increases
2; 1 since 1991	Employment Contracts Act of 1991
3	
2	
3; 2 since 1986	Up to 1986 national tripartite accords
3; gradually 2	In 1983, the engineering industry employer association and metal workers broke away from economy-wide negotiations; 1989 last central agreement for non-manual workers (SAF-PTK); 1991 and 1993 tripartite agreements.

### **Changes in employment protection legislation (EPL)**

The summary measure of EPL is the average of two indices measuring the strictness of EPL rules for regular and fixed-term contracts, as presented in Tables 6.5 and 6.6 in OECD (1994b). In particular, the two indices are country rankings based on the average of scores assigned to several key elements characterising regular and fixed-term contracts, respectively. Since this classification was made, there were significant changes in the EPL of several OECD countries, including Germany, France, the UK, Australia, Denmark, Portugal and Spain (see OECD, 1997b). These changes were considered, using the following procedure: (1) the country scores for each of the key elements of regular and fixed-term contracts were re-evaluated on the basis of the observed changes; (2) the overall country scores for regular and fixed-term contracts were re-calculated; and, (3) the summary EPL indexes were recalculated taking into account (for the countries with changes in EPL) how their new summary scores compared with those of countries that had no changes.

In other words, the original ranking presented in OECD (1994b) was used as a benchmark; each country whose EPL had changed was assigned a position in the new ranking similar to the country with the closest summary score. Along these lines, Germany had only a marginal change that did not modify its position in the overall country ranking. France moved gradually to a more restrictive EPL from 1989 (the index rose from 9.5 to 11.5 in 1995). The UK moved to a slightly less-restrictive EPL (the index fell from 2.25 to 2 in 1993). Australia moved firstly to a more restrictive EPL in 1993 (from 3.26 to 4) and then in the opposite direction in 1994 (from 4 to 3.5). Denmark moved to a somewhat more restrictive EPL in 1994 (from 3.25 to 3.5). Portugal moved to ease its very strict EPL slightly in 1989 and 1991 (from 12.5 to 11.5 and 11).

### **Testing for reverse causality**

To explore the possibility of reverse causality, Granger causality tests were run between, on the one hand, unemployment and, on the other hand, the generosity of unemployment benefits and the size of the tax wedge. The tests obviously had to be restricted to the variables that vary over time. Keeping this caveat in mind, the results in Table B3 do not give strong backing to the hypothesis of reverse causation. But there are a few exceptions. Thus, unemployment may have led changes in benefit generosity in Belgium, France and Italy.

**Table B.3 Testing for reverse causality  
(F-statistics of the Granger causality tests, 1970-1995)<sup>a</sup>**

Country	Test of the hypothesis that unemployment does not Granger-cause	
	Benefit generosity	Tax wedge
Australia	0.47	0.58
Austria	0.59	4.90**
Belgium	8.29***	1.32
Canada	0.95	0.53
Denmark	0.91	0.49
Finland	0.54	2.42
France	5.98***	0.68
West Germany	1.13	1.45
Ireland	0.74	5.23**
Italy	9.47***	1.51
Japan	2.43	0.75
Netherlands	3.11*	0.16
New Zealand	0.18	1.63
Norway	0.07	3.89**
Portugal	0.93	1.98
Spain	0.48	0.74
Sweden	0.14	0.74
UK	3.62**	0.17
US	3.56**	0.02

*Notes:*

\* = Statistically significant at 10% level

\*\* = Statistically significant at 5% level

\*\*\* = Statistically significant at 1% level

<sup>a</sup> F-statistics of the relevant hypotheses. Different lag structures of the dependent and independent variables were used to maximise the efficiency of the estimates and obtain white-noise residuals.

The hypothesis that unemployment does not lead benefit generosity is also rejected for the UK and the US; in the latter, this result may reflect the regular practice of extending benefit duration from 26 to 39 weeks during periods of recession. Similarly, the hypothesis that unemployment does not lead changes in the tax wedge is rejected for Austria, Ireland, and Norway. Here, rejection does not necessarily imply a political-economy link, but could just reflect the normal economic mechanism that as unemployment changes, government budgets are affected and tax changes may be enacted in response.

## Labor Market Flexibility as a Determinant of FDI Inflows

by Hazel Parcon,<sup>\*</sup>  
Department of Economics  
University of Hawai'i at Mānoa

Working Paper No. 08-07  
October 2008

### Abstract

This paper shows that labor market flexibility, measured by labor market standards and regulations, has two opposing effects on FDI inflows. Labor market regulations and standards decrease FDI inflows through the cost channel, but they increase FDI inflows through the productivity channel. Allowing for a non-linear relationship between different indicators of labor market flexibility and FDI inflows revealed that some degree of labor market standards and regulations may be attractive for foreign investors. Results strongly suggest that foreign investments to and from different countries and in different sectors are affected differently by different aspects of labor market standards and regulations.

**Key Words:** foreign direct investment, labor market flexibility  
**JEL Classification:** F16, F21

## I. Introduction

Globalization of production and more open economies have expanded the decision range of profit-maximizing firms on where to conduct business. A large portion of the literature on foreign direct investments (FDI) has examined the various determinants of FDI location. Some determinants of FDI location such as market size and distance are beyond the influence of policymakers in host countries. However, some institutional determinants such as tax and investment incentive structures are more malleable. One often-overlooked institutional determinant is the flexibility of the labor market. Labor market standards and regulations or any limitation placed on employment lead to labor market rigidity, which imposes costs on firms. Hence, a profit-maximizing firm would most likely want to locate in countries with more flexible labor markets. In addition, flexible labor markets afford firms more freedom to adjust to prevailing economic conditions. Therefore, it seems reasonable to assert that countries with rigid labor markets will have less FDI inflows. While the mainstream literature argues that a highly regulated labor market impose additional cost on firms, which may deter FDI inflows, another strand of the literature has claimed that a highly regulated labor market may help enhance labor relations and increase labor productivity. Moreover, by providing job security, labor market standards and regulations can add to social stability. And these attract FDI inflows.

While existing studies find *either* a positive or negative relationship between labor market flexibility and FDI inflows, no study has yet reconciled these two opposing effects, which I attempt to do in the current study. First, I present the simple model of Dewit, Gorg, and Montagna (2003) to demonstrate that labor market flexibility can have two opposing effects on the expected profit of a multinational company (MNC), and thus on the motivation of the latter to invest in other countries. I augment this simple model to show that the impact

of labor market flexibility on FDI inflows is ambiguous and not clear cut positive or negative as suggested by previous studies. Then, in my empirical specification, I allow for a non-linear relationship between labor market flexibility and FDI inflows. Previous studies have simply assumed that the relationship between the two is linear. Hence, when a negative relationship is found, the immediate policy implication is that countries should reduce their labor market standards and regulations to increase flexibility and therefore attract more FDI. However, when the possibility of non-linear effects is recognized, it may reveal that some degree of standards and regulations is valued by foreign investors and that it is only high degrees of standards and regulations that repels FDI. Thus, allowing for non-linearities can help reconcile the two opposing effects of labor market flexibility on FDI inflows.

Apart from the aforementioned, this study aims to contribute to the labor market-FDI literature in other ways. First, I use the International Labor Organization (ILO) Conventions that specifically pertain to hiring, at work, and firing standards to construct a simple measure of labor market flexibility. This is in contrast to previous studies that have used either the total number of ILO conventions ratified by each country or ILO conventions on workers' basic rights. In addition, I use the labor market flexibility indexes constructed by the World Bank (WB) from a survey of business people in over 150 countries. These indicators have not been previously used in the FDI-labor market flexibility literature. In contrast to previous studies that have used a single index to measure labor market flexibility, these indicators are disaggregated into hiring, hours at work, and firing regulations. Thus, it is easy to distinguish which among these labor market regulations are actually significant to foreign investors. I use the ILO conventions as a proxy for labor market standards and the WB indexes for labor market regulations. All countries may decide to observe the same standards, but may

implement them using different regulations. Hence, WB indicators represent the actual market conditions faced by firms.

Second, I verify whether the impact of labor market flexibility on FDI inflows matter more for developing than developed countries. Previous studies have investigated this possibility, but on a limited number of countries. I expanded the number of countries to test the robustness of previous studies' findings. In addition, most studies have pooled developed and developing countries, which I deem inappropriate.<sup>1</sup> Since FDI inflows to developed and developing countries have different motivations, this suggests that foreign investors may respond differently to labor market flexibility in different types of countries.

Finally, I test which of the two countries' MNCs – Japan or US, are more sensitive to labor market standards and regulations when choosing a host country for their FDI. This may be important especially for countries aiming to attract FDI particularly from these two countries. I disaggregate Japanese and US FDI by the recipient country level of development and by sector (manufacturing and non-manufacturing).

## **II. FDI-Labor Market Flexibility Literature**

The literature on FDI determinants has been motivated by theories of international business, which are firm-based; and by international trade, which is based on general equilibrium models. The former points to the OLI framework developed by Dunning (1977, 1981, and 2001), which argues that three conditions must be satisfied for FDI to occur: the firm must have both an ownership (O) and an internalization (I) advantage, and the host country must offer a locational (L) advantage. Both ownership and internalization advantages depend on the firm, while locational advantage depends on the host country. When potential

---

<sup>1</sup> This was earlier shown by Blonigen and Wang (2004).

countries are being considered by a MNC to host its FDI, the latter will choose based on the locational advantages offered by the former.

The OLI framework complements the more formal general equilibrium models used to explain FDI location, which is based on factor endowment differences, market sizes, and trade costs. The significance of these factors typically depends on whether FDI is of the horizontal or vertical type, as shown by general equilibrium models of Markusen (1984, 1995), Helpman (1984), Brainard (1993, 1997), Markusen and Venables (1995), Carr, Markusen, and Maskus (2001), and Markusen and Maskus (2001).

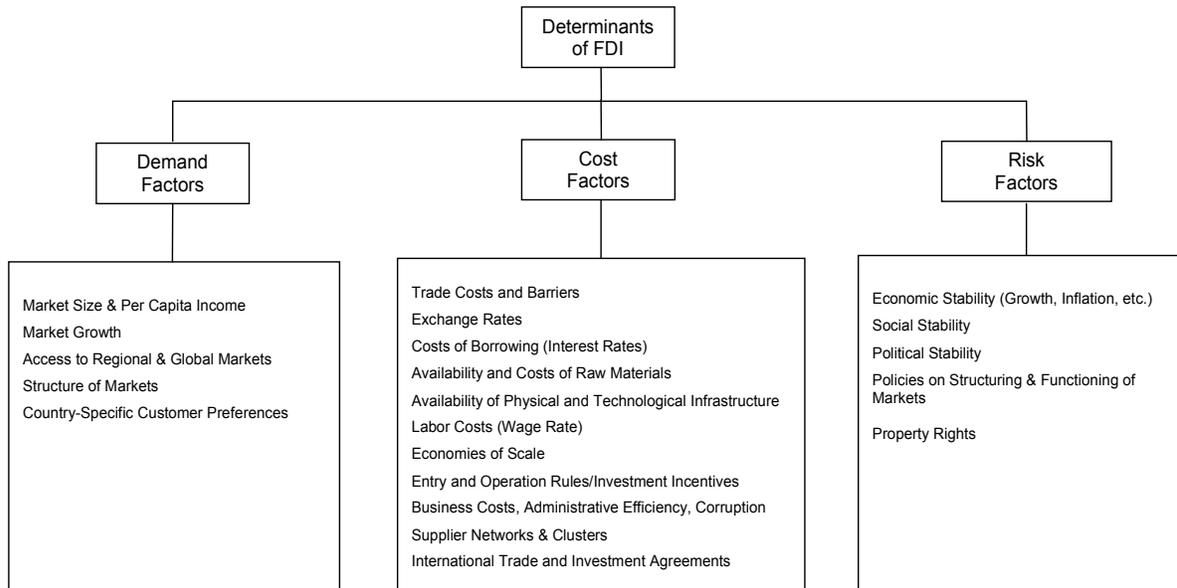

The two approaches in studying FDI determinants have produced a plethora of empirical work on FDI determinants at the firm and country level. These studies have considered various host country characteristics that may influence FDI inflows.<sup>2</sup> Figure 1 presents a classification of the various determinants identified in the literature. These factors may be divided into non-policy and policy factors. Non-policy factors would include market size, distance, relative factor endowments, economic growth, and risk/uncertainty. Policy factors meanwhile would include tax structure, investment incentives, product FDI restrictions, participation in trading agreements, and tariff regime.<sup>3</sup> An often overlooked policy factor is the labor market flexibility of the host country. This factor can be considered vital in the choice of FDI host country because an entire production process (for the case of horizontal FDI) or a part of it (for the case of vertical FDI) is left to the hands of the host country labor force.

---

<sup>2</sup> Chakrabarti (2001) have pointed out that some of these empirical studies form examples of ‘measurement without theory,’ as variables are searched for that show a significant influence on FDI and the relationship is explained *ex post*.

<sup>3</sup> See Whyman and Baimbridge (2006), Blonigen (2005), Nicoletti et al. (2003), and Yeyati, Stein, and Daude (2002) for a more detailed review of these factors.

Figure 1. Determinants of FDI

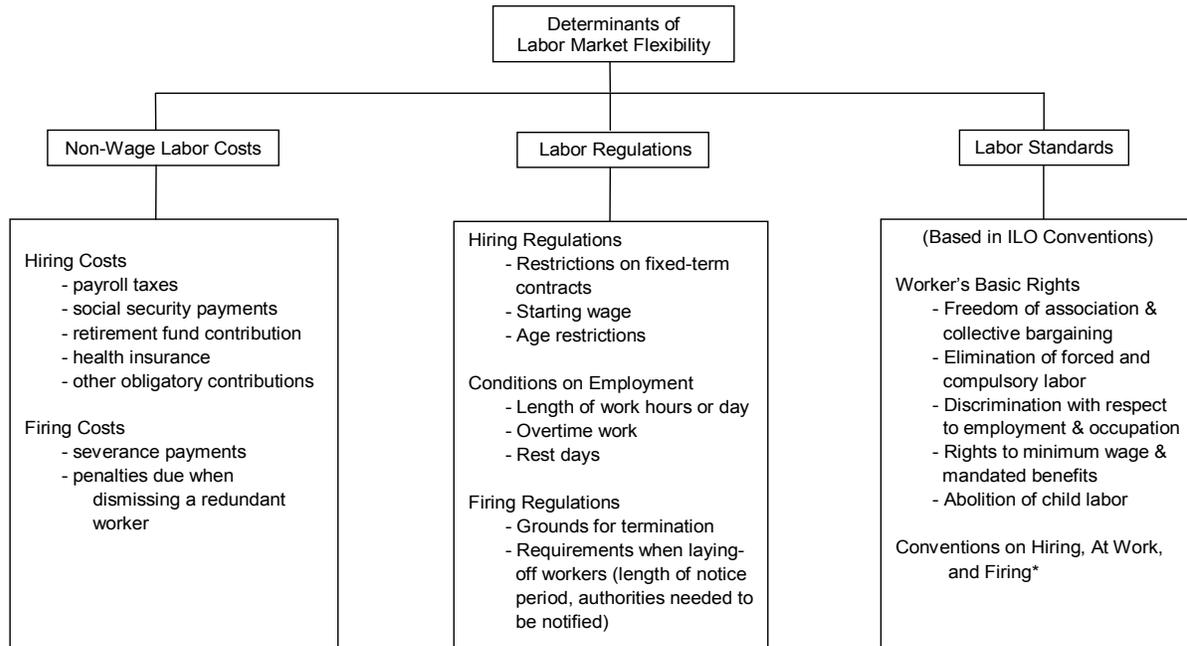

Source: Adopted by the author from Whyman and Baimbridge (2006)

According to Whyman and Baimbridge (2006), labor market flexibility refers to the degree to which labor market outcomes are determined by the operation of market forces free from rigidities and/or restrictions imposed by powerful actors such as the government, trade unions, and monopsony employers. Thus, a perfectly flexible labor market would imply the absence of all hindrances to the free operation of market forces. However, labor market standards, regulations, and non-wage labor costs prevent labor market outcomes to be freely determined by market forces. Figure 2 presents the various factors affecting labor market flexibility.

The literature on labor market effects on FDI inflows has mostly focused on the impact of labor cost as part of the firm's production cost. These studies frequently use average wage rate<sup>4</sup> and unit labor costs as measures of labor costs. While results of most

<sup>4</sup> Manufacturing wage rate is mostly used.

Figure 2. Determinants of Labor Market Flexibility

Note: \* - See Appendix Table 1.

Source: Compiled by the author from various studies

studies (Bellak et al. (2007), Fung et al. (2002), Cheng and Kwan (2000), Lucas (1993), Culem (1988), Schneider and Frey (1985), Flamm (1984)) conform to the mainstream literature that higher wages discourage FDI inflows, some studies found wages to be insignificantly and even positively related to FDI inflows (Owen (1982), Gupta (1983), Wheeler and Mody (1992)). What is common in these studies is that labor cost is usually measured using wage labor only. This may be reasonable since a large fraction of labor costs is composed of wage cost. However, this neglects the fact that labor cost consists of both wage and non-wage costs, where the latter includes hiring and firing costs. Of the studies that have considered the non-wage components of labor costs, the focus is mostly on European countries where non-wage costs are high relative to other countries. According to Whyman and Baimbridge (2006), the OECD Economic Outlook (2003), Buckley and Casson (1998),

and Moran (1998), a quarter to about one-third of total labor costs in European countries are non-wage costs. In addition, more studies have focused on firing than hiring costs. A possible reason for this is that hiring costs may be compensated by a reduction in wages in the long-run.<sup>5</sup> However, the same adjustment cannot be made for firing costs. The reason for this is that the firm may be faced with future uncertainties that may force it to unexpectedly lay-off employees or even exit the market. Since it is difficult to factor in all future uncertainties when a firm makes investment decisions, firing costs cannot really be planned ahead and therefore cannot be compensated with lower wages. Similarly, for studies using labor market regulations as an indicator of labor market flexibility, more studies have focused on firing than hiring regulations. There are likewise a considerable number of studies that have focused on regulations during the period of employment. As seen from Figure 2, conditions during the duration of employment and firing regulations constrain the ability of firms to easily respond to changes in market forces.

Bellak et al. (2007) included hiring costs (employers' contributions to social security and to contractual and private benefit plans) in their measure of total labor costs. Using a sample of selected European Countries, a negative and significant effect of total labor costs on FDI inflows was found. However, it is hard to tell whether hiring costs really made a significant impact because it was not separated from total labor cost. Haaland, Wooton, and Faggio (2003) theoretically demonstrated that firing costs, in particular severance payments, deters potential investment especially in risky industries. Though the empirical test verified the theoretical result, this study cannot offer generalizations since the model was tested on only three countries, namely, Romania, Poland, and Bulgaria. Covering a wider group of

---

<sup>5</sup> However, if minimum wage laws exist, then the shifting of non-wage costs to wages may only be partial. (OECD Economic Outlook, 2003)

OECD countries, Lee (2003) used an EPL (employment protection legislation) index<sup>6</sup> to show that labor market regulations have a strong negative impact on FDI inflows. However, the EPL index is limited since it simply averages the level of employment protection under a regular and a temporary contract. Gorg (2005) focused on the impact of labor market flexibility on US FDI in 33 host countries. He similarly found that countries with more liberal labor markets receive more FDI from the US. The study likewise revealed that the impact of labor market restrictions on US FDI inflows is the same regardless of the host country's level of economic development and economic risk/uncertainty. The labor market flexibility indicator used in this study is a single index that is based on a survey of managers across countries conducted by the World Economic Forum and published in the Global Competitiveness Report. The question asked on this survey is 'whether hiring and firing practices are too restricted by the government or are flexible enough'. An obvious drawback of this index is that it averages the effects of all hiring and firing practices. Thus, it is uncertain which of the two drives the result. Likewise, response to the survey question is likely to be subjective.

Non-wage labor costs and regulations are driven by policy objectives that are unrelated to FDI. Most of these objectives arise with the aim of protecting the employee. It is for this reason that labor market regulations are usually associated with EPL. In addition, labor market regulations arise as outcomes of negotiations of contracts and incentives. Regardless of the exact reason why non-wage costs and labor market regulations exist, they have important implications on the cross-country distribution of FDI. The mainstream literature suggests that non-wage costs and labor market regulations negatively affect FDI inflows in a potential host country due to: (1) the decrease in MNC's returns due to higher

---

<sup>6</sup> From Nicoletti, Scarpetta, and Boylaud (1999)

labor costs; and (2) the decrease in the capacity of the MNC to readily respond to supply and demand shocks.

One strand of the literature uses labor standards as an indicator of labor market flexibility. These studies usually use the ILO Conventions as indicators of labor market flexibility. Forteza and Rama (2001) argued that ratified ILO Conventions is a reasonable proxy for the rigidity of a country's labor market. In addition, Freeman (1993)<sup>7</sup> claimed that these conventions reflect the ideal regulatory framework from an institutionalist perspective, where employees are considered weaker than employers. Since ILO conventions restrict the ability of employers to decide on the terms and conditions of work, they are therefore seen as a source of labor market distortions. A number of studies have used ILO Conventions as indicators of labor market flexibility, namely, Rodrik (1995), Kucera (2001, 2002), Cooke and Noble (1998), and Daude, Mazza, and Morrison (2003).<sup>8</sup> Results of these studies mostly show that low labor standards might be a hindrance, rather than an attraction, for foreign investors. Moreover, these studies suggest that high labor standards facilitate human capital development and enhance political and social stability, which encourage FDI inflows.

The foregoing shows that labor market flexibility has numerous facets, which makes the exact relationship between labor market flexibility and FDI inflows harder to predict. In addition, the relationship between the two will be sensitive to the choice of labor market flexibility indicator used. Thus, depending on the indicator chosen, labor market flexibility can have two opposing effects on FDI inflows, as illustrated in Figure 3. On the one hand, labor market standards and regulations increase costs and decrease the ability of a firm to

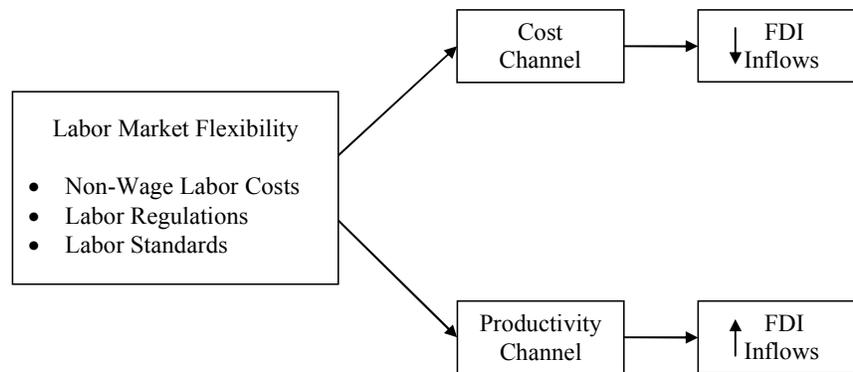

---

<sup>7</sup> Cited in Forteza and Rama (2001)

<sup>8</sup> Rodrik (1995) used the total number of ILO conventions ratified; Kucera (2001, 2002), Cooke and Noble (1998), and Daude et al. (2003) used an index based ILO Conventions 87 (Freedom of Association and Protection of the Rights to Organize) and 98 (Right to Organize and Collective Bargaining).

respond to market changes, which deters FDI. On the other hand, labor market standards and regulations enhance labor productivity, which attracts FDI.

Figure 3. The Impact of Labor Market Flexibility on FDI Inflows

### III. Theoretical Framework

I use the simple theoretical model developed by Dewit et al. (2003) to demonstrate how labor market flexibility in potential FDI host countries can affect the choice of the MNC on where to locate. There are two types of countries in the model, home and foreign, which are assumed to have the same production costs. Dewit et al. (2003) argued that the symmetric cost assumption allows the model to focus on employment regulations as the sole motivation for location choice of the firm. However, under this assumption, there will be no motivation for vertical FDI, which mainly occurs to take advantage of differences in production costs between home and foreign country. Therefore, I slightly altered the assumption of the model by assuming that the choice of the MNC is among potential FDI host countries. This would accommodate both horizontal and vertical FDI. Therefore, even if production costs are assumed the same between the potential host countries, if FDI is of the vertical type, then the

choice must be between countries that have the same lower production costs than the FDI source country. Furthermore, I assume that the profit-maximizing MNC in the home country has already recognized that it is optimal for it to invest in a foreign country, where horizontal FDI is motivated by market access and vertical FDI is motivated by cost advantage.

The firm is a monopolist that chooses among countries,  $C_1, \dots, C_n$ , as the host country for its FDI. There are two periods in the model. Demand in period 1 is known by the firm for certain, but demand in period 2 has some degree of uncertainty. Therefore, the inverse demand curves in periods 1 and 2 are given by  $p_1 = a - q_1$  and  $p_2 = a - q_2 + u$ , respectively, where  $p_t$  and  $q_t$  are the price and quantity in period  $t$  ( $t=1, 2$ ),  $a$  is a positive constant and  $u$  is a stochastic demand component, with mean  $E(u) = 0$  and variance  $v$ . Since the firm faces uncertainty in period 2, it values labor market flexibility. In the event of a decrease in demand in period 2, it has to cut its production, which means it may have to resort to cutting employment. Similarly, when demand increases in period 2, the firm wants to increase its production, which means it may want to increase employment. In either case, hiring and firing of employees can be costly, notably when the labor market is rigid.

The total variable cost in location  $i$  ( $i=1, \dots, n$ ) is given by:

$$(1) \quad \text{TVC}_i = c_i \sum_{t=1}^2 q_t + \frac{\lambda_i}{2} (q_2 - q_1)^2,$$

where  $c_i$  is the marginal cost of production in location  $i$ , which is assumed to be the same in both periods.  $\lambda_i$  is the degree of labor market inflexibility in location  $i$ . The higher  $\lambda_i$  is, the more stringent the labor market in location  $i$  is. When the firm decides to alter its output in period 2,  $|q_2 - q_1| > 0$ ; otherwise,  $|q_2 - q_1| = 0$ . Thus, the second term in (1) reflects the adjustment cost when output level is changed.

The fixed set-up cost in location  $i$  is given by:

$$(2) \quad FC_i = \phi + \delta_i,$$

where  $\phi$  is a constant fixed cost faced by the MNC regardless of the location chosen and  $\delta_i$  is a location-specific fixed cost.

To maximize expected total profits,  $E(\Pi) = \Pi_1 + E(\Pi_2)$ , the MNC chooses its optimal output in location  $i$  in each period given by:

$$(3) \quad q_{i1} = \frac{a - c_i}{2}$$

$$(4) \quad q_{i2} = \frac{a - c_i}{2} + \frac{u}{2 + \lambda_i}$$

Clearly, with uncertainty, the MNC will be more flexible in period 2 if  $\lambda_i$  is low, since

$\frac{dq_{i2}}{du} \left( = \frac{1}{2 + \lambda_i} \right)$  is decreasing in  $\lambda_i$ . If location  $i$  has an inflexible labor market (high  $\lambda_i$ ), the

MNC optimally chooses to adjust its period 2 output by a small amount in the face of uncertainty.

The maximized expected profit is given by:

$$(5) \quad E(\Pi_i) = 2 \left( \frac{a - c}{2} \right)^2 + \frac{v}{2(2 + \lambda_i)} - FC_i.$$

Therefore,

$$(6) \quad \frac{dE(\Pi_i)}{d\lambda_i} = -\frac{v}{[2(2 + \lambda_i)]^2} < 0.$$

This implies that the MNC will have greater expected profits when it chooses the location with more flexible labor market (low  $\lambda_i$ ). Thus, more FDI is expected to flow in location  $i$  as the expected profits in location  $i$  increase.

The foregoing illustrates how labor market regulations can constrain the decision of firms to respond readily to changes in the economic environment. A firm experiencing an

unexpected decrease in demand may decide to lay-off workers. However, doing so is not costless and may not be an easy process. The firm has to deal with regulations on notice period and severance payments. Similarly, when a firm unexpectedly experiences an increase in demand, even if it wants to increase employment of labor in response to the market change, hiring of new employees or increasing work hours will come at a cost. Hence, a MNC would have to take into account the state of the labor market in their choice of host country. When labor markets have stringent regulations, they are considered less flexible since they cause firms to slow down the reallocation of their resources in response to market changes, which in turn can be costly for firms.

What the preceding does not show, however, is that labor standards and regulations, though restrictive from the point of view of firms, exist to protect the interest of workers. For instance, if there were no restrictions on work hours and overtime pay, a firm can just require its existing employees to work for longer hours to meet an increase in demand for its good and just pay the regular hourly wage for the additional hours of work. Beyond some number of work hours, however, this practice may be considered exploitative. In addition, labor standards may be established to promote long-lasting work relationships and provide job security. For instance, firms may respond to the rigidity in the labor market by training employees in various functions, which increases within firm or internal flexibility. This reduces the cost associated with hiring and firing of workers. Moreover, if firms provide more employment protection, they may find that their workers are more loyal and hard-working. High labor standards may likewise encourage human capital development. An example is the ILO Convention on paid educational leave, which increases the cost of employers, but enhances human capital development. Social stability may likewise result from the job security that certain labor standards and regulations provide. Therefore, labor

regulations and standards can actually have a positive impact on FDI inflows by enhancing the aggregate labor productivity of a country. If this is the case, it is possible for certain labor market regulations and standards to decrease the marginal cost of production in location  $i$ , that is,  $c$  can be a negative function of  $\lambda$ . Thus, (5) and (6) can be alternatively written as

$$(5') \quad E(\Pi_i) = 2\left(\frac{a - c(\lambda)}{2}\right)^2 + \frac{v}{2(2 + \lambda_i)} - FC_i$$

$$(6') \quad \frac{dE(\Pi_i)}{d\lambda_i} = -\left(\frac{a - c(\lambda)}{2}\right)c'(\lambda) - \frac{v}{[2(2 + \lambda_i)]^2} > 0.$$

where  $c'(\lambda) < 0$ . The first term in (6') represents the positive impact of labor market regulations and standards on the MNC's expected profits due to increased labor productivity that decreases the marginal cost of production. The second term, meanwhile, represents the negative impact of labor market regulations and standards on the MNC's expected profits due to adjustment costs incurred by the firm when it changes its production decisions as a result of market uncertainties. Thus, the sign of  $\frac{dE(\Pi_i)}{d\lambda_i}$  is ambiguous, depending on which effect

dominates. Based on the foregoing, I hypothesize that labor market flexibility can influence the cross-country differences in FDI inflows through two channels: costs and productivity.

***Hypothesis: An increase in labor market inflexibility will decrease FDI inflows through the cost channel and will increase FDI inflows through the productivity channel.***

#### IV. Empirical Methodology and Data

To empirically test whether labor market flexibility has a significant impact on cross-country differences in FDI inflows, the following equation will be estimated:

$$(7) \quad \log(\text{FDI}_{ji}) = \alpha + \beta \text{LM}_i + \gamma X_i + \varepsilon_{ji},$$

where FDI inflows from source  $j$  to country  $i$  is regressed on a measure of labor market flexibility (LM) of country  $i$  and other country  $i$  characteristics,  $X_i$ , known to affect FDI inflows.  $\beta$  is the coefficient of interest and  $\varepsilon$  is a random error term. Stated in this manner, (7) is a reduced form representation of the FDI-labor market flexibility relationship. Whether labor market flexibility has a positive or negative impact on FDI inflows depends on the net impact of the former on the expected profits of the MNC.

Equation (7) assumes a linear relationship between labor market flexibility and FDI inflows. When labor market standards and regulations are used as indicators of labor market flexibility and when a negative effect on FDI inflows is found, the outright conclusion is that labor market flexibility should be increased by reducing standards and regulations in order to attract more FDI inflows. And when a positive relationship is found, the explanation given for the seemingly surprising result is that labor market standards and regulations increase labor productivity. Thus, standards and regulations should be encouraged in order to attract more FDI inflows. Note that when only a linear relationship is assumed, the relationship between labor market flexibility and FDI inflows could only be either positive or negative at all levels of labor market standards and regulations.

The theoretical model presented in the preceding section recognizes that labor market standards and regulations may reduce the marginal cost of production by increasing aggregate labor productivity. At the same time, labor standards and regulations increase the total variable cost faced by a MNC when an adjustment needs to be done in response to market uncertainties. To allow for these two possible channels, I add a squared term for the labor market flexibility indicator. Hence, equation (7) becomes

$$(7') \quad \log(\text{FDI}_{ji}) = \alpha + \beta_1 \text{LM}_i + \beta_2 \text{LM}_i^2 + \gamma X_i + \varepsilon_{ji}.$$

There are several possibilities in the signs of  $\beta_1$  and  $\beta_2$ .

First,  $\beta_1 > 0$  and  $\beta_2 < 0$ . This implies that labor market standards and regulations increase FDI inflows at a decreasing rate. If this case holds, then this would suggest that some degree of labor market standards and regulations is helpful in attracting FDI inflows. But higher levels of regulation will be too costly and eventually ward off investors. This case may likewise suggest that the productivity effect of standards and regulations can have a diminishing effect on FDI inflows.

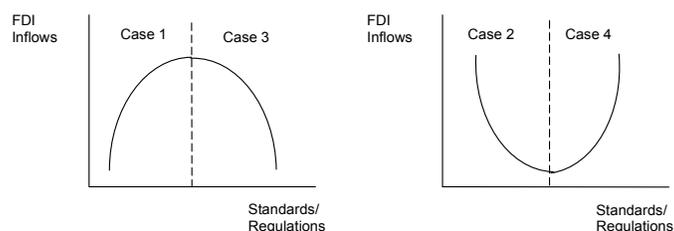

Second,  $\beta_1 < 0$  and  $\beta_2 > 0$ . This implies that labor market standards and regulations decrease FDI inflows at a decreasing rate. If this case holds, the marginal increase in costs becomes smaller as standards and regulations increase; that is, the negative impact of regulations will have a diminishing effect on FDI inflows.

Third,  $\beta_1 < 0$  and  $\beta_2 < 0$ . This implies that labor market standards and regulations decrease FDI inflows at an increasing rate. If this case holds, then the cost channel dominates the productivity channel.

Fourth,  $\beta_1 > 0$  and  $\beta_2 > 0$ . This implies that labor market regulations increase FDI inflows at an increasing rate. If this case holds, then the productivity channel dominates the cost channel.

The aforementioned cases are illustrated in Figure 4. The four cases suggest that the impact of labor market regulations on FDI inflows depends on whether a country has high or low levels of standards or regulations and on which of the two channels is more dominant.

Figure 4. The Non-linear Effects of Labor Market Standards/Regulations on FDI Inflows

On the choice of labor market flexibility indicator, I depart from previous studies in two ways. First, I do not use the total number of ILO conventions or number of ILO conventions pertaining to workers' basic rights ratified by each country as an indicator of LMF. Using the total number of ILO conventions ratified as an indicator of LMF is inappropriate since the conventions cover a wide variety of employment regulations. I choose only ILO conventions that specifically pertain to *hiring, at work, and firing standards*. Appendix Table 1 summarizes the conventions classified under each category. I do not aggregate the conventions covering these three categories in order to distinguish which among the three is most important for foreign investors. Moreover, rather than simply obtaining the number of conventions ratified by each country under each category, I consider the number of conventions ratified by each country  $i$  relative to the maximum possible number of regulations for each category  $k$  (where  $k = \text{hiring, at work, firing standards}$ ) for each year  $t$ , that is,

$$k \text{ index}_{it} = \frac{(\text{Number of ILO Ratifications for Category } k)_{it}}{(\text{Total Number of ILO Ratifications for Category } k)_t} \times 100.$$

The larger the index is, the greater are the number of conventions ratified by a country. For instance, in 1992, 21 ILO Conventions were classified under at work category. Of these conventions, Australia has ratified only one. Thus, at work index for Australia for 1992 is  $(1/21) \times 100$  or 4.80. In 1993, an additional convention under at work category was introduced,<sup>9</sup> but Australia did not ratify the convention. Hence, at work index for Australia in 1993 went down to  $(1/22) \times 100$  or 4.50. Thus, if a convention is not ratified by a country in a given year, the index will decrease for the country. If no convention is introduced by the ILO in a given year, then the indexes remain the same for all countries. An exception happens

---

<sup>9</sup> Convention No. 174 (Prevention of Major Industrial Accidents)

when a country denounces a previously ratified convention. For instance, Brazil ratified Convention No. 158 (Termination of Employment) in 1982, but denounced the convention in 1996. Hence, though no convention was ratified in 1996, the firing index for Brazil decreased from 20 in 1995 to 0 in 1996.

Second, I use various labor market flexibility indicators obtained from the *Doing Business* Database of the World Bank (WB). The indicators focus on the regulation of employment, specifically the hiring and firing of workers and the rigidity of work hours. They were based on a survey that started in 2003, which was conducted on various firms in over 150 countries. To make the data comparable across countries, the survey was designed to reflect the employment regulation enforcement across countries. Thus, in contrast to the ILO indicators which represent the labor standards countries agreed in principle to observe, the WB indicators represent the actual regulations faced by investors in different countries. Specific assumptions about the worker and the business were provided in the survey and respondents were asked to answer based on the given assumptions and the existing labor regulations in the country.<sup>10</sup> Hence, subjectivity of responses is eliminated, in contrast to other indicators of labor market flexibility. Out of the survey, the database provides a rigidity of employment index (REI), which is a weighted average of the difficulty of hiring index (DHI), rigidity of hours index (RHI), and difficulty of firing index (DFI). Higher values of the indexes indicate more rigid regulation. A summary of the components of the indexes is provided in Appendix Table 2.

Compared to single aggregate indexes used in previous studies, the disaggregation of the ILO Conventions and the WB's rigidity of employment index into different components is appealing. The disaggregated indicators enable one to see whether the impacts of the

---

<sup>10</sup> A copy of the actual questionnaire can be downloaded from <http://www.doingbusiness.org/Methodology/>.

different categories of standards and regulations are equally significant for foreign investors. However, as with any other indicator, both sets of labor market flexibility indicators have drawbacks.

Although the ILO actively monitors the observance of the ratified conventions, it does not have the legal power to penalize a nation from not observing a convention that it has ratified. The most that it can do is to rely on moral suasion. Hence, a limitation of using the ILO conventions as indicators of labor market flexibility is that they may just measure the latter as stated on paper and not necessarily in practice. Another drawback of the ILO Conventions is that whether countries ratify a convention or not may depend on its level of economic development. Appendix Table 3 summarizes the percentage of developed and developing countries with ILO and WB labor market flexibility indicators above and below the mean values of these indicators. The table reveals that a greater proportion of developed countries have ILO indexes above the mean. This implies that developed countries generally ratify more conventions than developing countries. This is most apparent for the firing index where 71 percent of developed countries have an index above the mean, while only 38 percent of developing countries have an index above the mean.

A more preferred indicator of labor market flexibility is one that does not only capture labor regulations as stated on paper, but which captures their enforcement and effect on firms' operations as well. The labor market flexibility indicators from the WB satisfy this characteristic. In addition, as seen in Appendix Table 4, compared to the ILO indexes, there seem to be no apparent correlation between a country's level of development and the WB indexes.<sup>11</sup> Hence, in these aspects the WB indicators are preferred over the ILO indicators. A

---

<sup>11</sup> Although among the ILO indicators, only firing standards seem to be highly correlated with a country's level of development. Correlation between the developing country dummy and firing standards is -0.39, which imply that developing countries generally have lesser firing standards than developed countries.

drawback of using the WB labor market flexibility indicators, however, is that the values of the indexes do not change for any country for the period covered by the survey.<sup>12</sup>

I proceed with the aforementioned limitations in mind. Both sets of labor market flexibility indicators will be used to estimate the impact of labor market flexibility on FDI inflows. Fixed effects technique is used to estimate equations (7) and (7') when the ILO indexes are used as indicators. Fixed effects estimation eliminates the effect of time-invariant omitted variables. Such estimation method can be used since the ILO indexes vary for countries for the period 1990-2005. However, fixed effects estimation cannot be used when the WB indexes are used as indicators since the indexes are time-invariant. Thus, when using the WB indexes, data is pooled across years for all 165 countries, where each country-year observation is treated as a single observation. Since I am only able to estimate a simple cross-country relationship between FDI inflows and labor market flexibility when using the WB indexes, there is always a risk that the correlations I document are spurious. To address this concern, I include various variables that the literature suggests are correlated with FDI inflows. This lessens the possibility that the LMF indicators will capture the effect of omitted variables. I likewise included dummy variables for each year to account for year effects.<sup>13</sup>

I consider three sources (j) of FDI, namely, the rest of the world (ROW), Japan, and the United States. A cursory inspection of the FDI data shows that all countries included in

---

<sup>12</sup> Statistically, this is a limitation. In reality, not much can really be done about it since labor market regulations rarely change from one year to another. Since many regulations have to be passed into law before being implemented, it is necessarily expected that regulations will not change on an annual basis.

<sup>13</sup> Based on existing literature, the following explanatory variables are included in the estimations: wage and its square, GDP per capita and its square, trade as a percent of GDP, inflation rate, tax on goods and services, labor force participation rate, population, literacy rate, exchange rate, external debt as a percentage of GDP, capital account openness index, dummy variable whether the form of government is democratic or not, corruption index, manufacturing value added (included in estimation for the manufacturing sector), distance from US (included in estimation for US FDI), distance from Japan (included in the estimation for Japanese FDI), and dummy variables for membership in different preferential trading agreements (AFTA, NAFTA, COMESA, MERCOSUR, CARICOM, EU). Variance inflation factor was checked for each regression to ensure that there is no serious multicollinearity among the explanatory variables. Robust standards errors are also used to minimize the problem of heteroskedasticity.

the study have received FDI inflows from the ROW in the years covered by the study. However, not all countries have received FDI from Japan and US. Therefore, Tobit estimation is the appropriate method of estimation when considering FDI coming from US and Japan. Appendix Table 5 presents the description of variables and their corresponding sources. Appendix Table 6 presents the summary statistics of these variables.

## V. Results

Table 1A presents the results of the estimations using the constructed ILO indexes as the labor market flexibility indicators. Panel A lists the coefficients for the sample of all countries. Panels B and C, meanwhile, contain the coefficients for the developed and developing countries samples, respectively.

Panel A reveals that countries with more hiring and at work standards generally receive more FDI inflows. A 10 unit increase in hiring and at work indexes increases FDI inflows by about 7-11 and 14 percent, respectively, as seen in columns (1), (2), and (4). There is no discernable non-linear relationship between FDI inflows and the ILO standards. In addition, firing standards are statistically insignificant in affecting FDI inflows. The results for the developed countries sample are very similar to the pooled sample as seen in Panel B. Hiring and at work standards are statistically significant, but firing standards are not. A 10 unit increase in hiring and at work indexes will increase FDI inflows to developed countries by about 11-19 and 16 percent, respectively, as seen in columns (1), (2), and (4).

The result for the developing countries sample is quite different as revealed in Panel C. Hiring standards are only weakly statistically significant in affecting FDI inflows, while at work and firing standards are statistically significant in explaining FDI inflows. A 10 unit increase in at work index increases FDI inflows by about 14 percent, as seen in columns (2).

Notes: Values in ( ) are standards errors. \*\* and \* indicate significance at 5% and 10% level, respectively. Coefficients estimates of other explanatory variables appear in Appendix Table 7.

A non-linear relationship is apparent between firing standards and FDI inflows. Developing countries with more firing standards will generally attract more FDI inflows such that a 10 unit increase in the firing index will increase FDI inflows by about 15 percent, as seen in column (6). However, when firing standards reach a certain level, FDI inflows will start to decrease. Developing countries with firing index below 32 will find that FDI inflows will still increase if firing standards are increased.<sup>14</sup> However, countries with firing index above 32 may find that increasing firing standards any further will decrease their FDI inflows. Of the 124 developing countries in the sample, only 19 countries have firing index above 32. Thus, my results suggest that most developing countries can still increase their firing standards sans the fear of repelling FDI inflows.<sup>15</sup>

The preceding results suggest that countries with higher labor market standards generally receive more FDI inflows, suggesting that MNCs value labor market standards in host countries. Moreover, results show that not all labor market standards have the same and significant effects on FDI inflows to developed and developing countries.

Table 1B presents the results of the estimations using the WB indexes as the labor market flexibility indicators. Again, Panels A, B, and C list the results for the pooled, developed, and developing countries samples, respectively.

Panel A, column (1) shows that based on the aggregate index – rigidity of employment, labor market regulations do not have a significant impact on FDI inflows. However, when this index is disaggregated into its components, regulations on work hours and firing have statistically significant impact on FDI inflows, as seen in columns (3) and (4).

---

<sup>14</sup> This is calculated as  $(-\beta_1/2\beta_2)$ .

<sup>15</sup> For instance, the following developing countries have firing index below 32: Angola, Bangladesh, Cambodia, Cote d'Ivoire, Guatemala, Mongolia, Mozambique, Rwanda, and Vietnam; and the following have firing index above 32: Mexico, Madagascar, and Zambia.

Notes: Values in ( ) are standard robust errors. \*\* and \* indicate significance at 5% and 10% level, respectively. Coefficients estimates of other explanatory variables appear in Appendix Table 7.

A 10 unit increase in the rigidity of hours index will increase FDI inflows by 2 percent, while a 10 unit increase in the difficulty of firing index will decrease FDI inflows by 2.4 percent.

When a non-linear relationship is allowed between the labor market flexibility indicators and FDI inflows, the rigidity of employment index gains statistical significance as seen in column (4). A 10 unit increase in the rigidity of employment index decreases FDI inflows by about 8 percent. However, when the index is disaggregated into its components, there is no apparent non-linear relationship between FDI inflows and the disaggregated indexes as seen in columns (6) – (8).<sup>16</sup>

Panel B, columns (1)-(4) reveal that when only a linear relationship is allowed between labor market flexibility and FDI inflows to developed countries, the former is insignificant in explaining the latter.<sup>17</sup> A statistically significant relationship between labor market flexibility and FDI inflows in developed countries is strongly evident only when non-linear relationship is allowed, as seen in columns (5) and (7). A 10 unit increase in the rigidity of employment index decreases FDI inflows by about 40 percent, and this can be attributed to the rigidity of hours. A 10 unit increase in the rigidity of hours index decreases FDI inflows by about 45 percent. Thus, MNCs are discouraged to invest in developed countries with rigid work hour regulations, but are indifferent as regards hiring and firing regulations.<sup>18</sup>

Panel C shows that a 10 unit increase in the rigidity of employment index decreases FDI inflows to developing countries by about 3-10 percent, as seen in columns (1) and (5). Among the components of the aggregate index, the difficulty of hiring index is marginally significant, as seen in column (2). Both the rigidity of hours and difficulty of firing indexes

---

<sup>16</sup> Squared term for difficulty of firing is insignificant.

<sup>17</sup> Difficulty of firing index in column (4) is only marginally significant.

<sup>18</sup> Firing regulations are only weakly statistically significant and the economic impact is quite small – 3 percent, as seen in column (4).

are strongly statistically significant. A 10 unit increase in the rigidity of hours index will increase FDI inflows by about 14 percent as seen in column (7), while a 10 unit increase in the difficulty of firing index will decrease FDI inflows by about 3-9 percent, as seen in columns (4) and (8).

The preceding results show that it is important to look not only at aggregate indexes, as important relationships may be concealed when analysis is based only on an aggregate index. For instance, the negative relationship found for the rigidity of employment index and FDI inflows to developing countries may give an impression that all types of labor market regulations should be reduced in developing countries in order to attract more FDI inflows. However, once the index is disaggregated into its components, only firing regulations have a negative impact on FDI inflows. In fact, regulations on work hours have a positive impact on FDI inflows up to a certain limit. Countries with rigidity of hours index below 40 can still increase their work hour regulations and still have an increase in their FDI inflows. However, countries with rigidity of hours index above 40 may find their FDI inflows decreasing if regulations on work hours are further increased. Of the 124 developing countries in the sample, 91 countries have rigidity of hours index below 40. My results imply that a great majority of developing countries can still increase their work hour regulations and still increase their FDI inflows.

Regulations on work hours may improve the productivity of workers, which may explain the positive impact of the rigidity of hours index on FDI inflows. This suggests that though regulations constrain work hours in developing countries, this is not necessarily seen by foreign investors as a hindrance to their operations. Making employees work beyond a certain number of hours may actually decrease their productivity. This likewise suggests that foreign investors do not necessarily gravitate towards countries where workers are made to

work for unreasonable number of hours.<sup>19</sup> Regulations on firing, however, may slow down the operations of firms, especially when an adjustment on the employment level needs to be made, which explains the negative relationship between the difficulty of firing index and FDI inflows. These results are consistent with the theoretical model presented in the previous section. On the one hand, labor market regulations decrease the marginal cost of production by increasing labor productivity, which increases FDI inflows. On the other hand, labor market regulations increase the adjustment costs faced by a firm when it decides to change its employment level, which deters FDI inflows.

Similar to the estimations using ILO indexes, results show that not all labor market regulations have the same and significant effects on FDI inflows to developed and developing countries. Based on the rigidity of employment index, labor market regulations have a larger negative impact on developed than developing countries. A 10 unit increase in the rigidity of employment index will reduce FDI inflows to developed countries by about 40 percent and only about 10 percent for developing countries. This is in contrast to the prediction of Haaland et al. (2003) that labor market flexibility should have a greater impact in developing than developed countries. A possible explanation for this is that worker compensation is in general more costly in developed than developing countries. Moreover, allowing for non-linear effects is important, as it may reveal additional information that is concealed when the relationship is just assumed to be linear. For instance, the positive impact of work hour regulations on FDI inflows to developing countries is only evident when a non-linear relationship is specified.

---

<sup>19</sup> An example is the issue about a textile factory in India where laborers are made to work from dawn until late in the evening. This factory was exposed to produce garments for the American retail clothing chain GAP Inc. As a response, the latter severed all its ties with suppliers that are known to manufacture garments in deplorable working conditions.

The results in Tables 1A and 1B are very suggestive. While labor market standards generally increase FDI inflows, labor market regulations have a greater tendency of reducing FDI inflows. These imply that foreign investors prefer to invest in countries with some degree of labor market standards as these may signal higher aggregate labor productivity. However, foreign investors may be wary of some labor market regulations because these translate to actual costs. These suggest that developing countries need not “race to the bottom” in order to attract FDI inflows. What developing countries need to do is to find a proper balance of labor market standards and regulations such that these can increase labor productivity, but at the same time not becoming too rigid and costly from the point of view of MNCs.

Among the other explanatory variables, wage, GDP per capita, inflation rate, trade, tax, exchange rate, labor force participation rate, literacy rate, population, capital account openness, external debt, and corruption index appear significant in explaining FDI inflows, depending on the estimation technique used. Results are shown in Appendix Tables 7A and 7B.

Next, equations (7) and (7') are estimated for FDI inflows from Japan and US. Tables 2A and 2B display the results using ILO and WB indexes as labor market flexibility indicators, respectively. Table 2A, Panel A reveals that the decision of MNCs from both Japan and US to invest in other countries is affected by the potential host countries' labor market standards. It is noticeable though that Japanese MNCs are more sensitive to most labor market standards as revealed by the larger magnitude of effects on Japanese FDI inflows. In general, FDI inflows from Japan and US decrease as hiring and at work standards increase, but FDI inflows increase as firing standards increase.

Notes: Values in ( ) are standard errors. \*\* and \* indicate significance at 5% and 10% level, respectively.

Panel B reveals that hiring standards are insignificant for Japanese MNCs when they choose to invest in developed countries, but at work and firing standards are important for them. In particular, an increase in at work standards decreases FDI inflows from Japan, but an increase in firing standards increases FDI inflows from Japan. Meanwhile, US MNCs are sensitive to all labor market standards in developed countries. An increase in both hiring and at work standards decreases FDI inflows from US, but an increase in firing standards increases FDI inflows.

Panel C reveals that Japanese MNCs are sensitive to all labor market standards in developing countries. Japanese MNCs are most sensitive to at work standards in developing countries, such that a 10 unit increase in at work index will decrease FDI inflows by about 54-64 percent, as seen in columns (2) and (5). Firing standards, meanwhile, exert the least impact - a 10 unit increase in firing index will decrease FDI inflows by about 22 percent, as seen in column (3). Similarly, US MNCs are sensitive to all labor market standards in developing countries. A 10 unit increase in hiring index will decrease FDI inflows by only about 2 percent. A non-linear relationship, meanwhile, is found for both at work and firing standards. A 10 unit increase in at work and firing indexes will increase FDI inflows by about 9 and 31 percent, respectively. This positive effect, however, has a limit. Developing countries with at work and firing indexes beyond 23 and 20, respectively, may experience a decline in US FDI inflows if they further increase their at work and firing standards. Of the 124 developing countries considered, 89 countries have at work index below 23 and 108 countries have firing index below 20. This implies that most developing countries can further increase their at work and firing standards and still increase their FDI inflows from US.

Similar to ILO indexes, Table 2B, Panel A reveals that WB indexes are significant determinants of FDI inflows from Japan and US, implying that investors from both countries

are sensitive to labor market regulations. In general, countries with higher labor market regulations receive fewer FDI from Japan and US. Results likewise reveal that Japanese MNCs are more sensitive to regulations than US MNCs, as implied by the larger magnitude of the coefficients of the indexes for the case of Japan. For both countries, it is evident there is a non-linear relationship between labor market regulations and FDI inflows, and that firing regulations exert the least impact among the labor market regulations considered.

Panels B and C similarly show that Japanese MNCs are in general more sensitive to labor market regulations than US MNCs, except for firing regulations in developing countries. Firing regulations are insignificant for Japanese FDI inflows to developing countries. However, a 10 unit increase in the firing index reduces US FDI inflows to developing countries by about 6 percent.

The foregoing suggests that investors from different countries have different preferences for different labor market standards and regulations. In general, Japanese MNCs are more sensitive to labor market standards and regulations than US MNCs. This finding is consistent with the conclusion of Lee (2003). MNCs from both countries are likewise more negatively affected by hiring and work hour regulations than firing regulations in both developed and developing countries. Firing standards and regulations have the least negative impact on FDI inflows. Firing standards even exert a positive impact on US FDI inflows to all countries.

Next, I consider the possibility that the impact of labor market flexibility on FDI inflows varies per sector. Tables 3A and 3B present estimations for manufacturing<sup>20</sup> and non-manufacturing<sup>21</sup> FDI inflows from Japan and United States.<sup>22</sup>

---

<sup>20</sup> Manufacturing sector includes production of food, textile, lumber and pulp, chemical, metal, machinery, electrical, and transport.

Notes: Values in ( ) are standards errors. \*\* and \* indicate significance at 5% and 10% level, respectively.

Table 3A, Panel A reveals that Japanese FDI inflows to the manufacturing sector are very sensitive to both hiring and firing standards, but insensitive to at work standards. An increase in hiring standards decreases FDI inflows and an increase in firing standards increases FDI inflows as seen in columns (1), (4), and (6). Panel B shows that Japanese FDI inflows to the non-manufacturing sector, meanwhile, are very sensitive to all labor market

<sup>21</sup> Non-manufacturing sector includes farming and forestry, fishery, mining, construction, trade, finance and insurance, service, transportation, real estate, professional, scientific, and technical services, and information.

<sup>22</sup> A caveat to these estimations is that not all countries have reported breakdown of manufacturing and non-manufacturing FDI inflows. Countries with positive values of FDI inflows are therefore those countries which reported a breakdown, but this may not necessarily mean that those with zero FDI inflows did not actually have FDI inflows.

standards. In general, higher labor market standards decreases Japanese FDI inflows to the non-manufacturing sector. The results for US FDI inflows to the manufacturing and non-manufacturing sectors reveal quite a different picture. In contrast to Japanese FDI, US FDI inflows to both sectors are in general positively affected by labor market standards. The only exception is that at work standards are insignificant for US manufacturing FDI.

Notes: Values in ( ) are standards errors. \*\* and \* indicate significance at 5% and 10% level, respectively.

Table 3B reveals that both manufacturing and non-manufacturing FDI inflows from both Japan and US are negatively affected by regulations. It is likewise noteworthy that a

non-linear relationship between labor market regulations and FDI inflows exist. The implications of these results for the case of US FDI inflows are very similar to what is suggested by the findings in Tables 1A and 1B. In particular, while US MNCs invest more in countries with higher labor standards, regulations have a greater tendency of reducing US FDI inflows. This implies that US foreign investors prefer to invest in countries with some degree of labor market standards as these may signal higher aggregate labor productivity, but they may be wary of some labor market regulations because these translate to actual costs.

Though results show that both manufacturing and non-manufacturing FDI inflows are sensitive to labor market standards and regulations, the impact of the latter on the former varies, depending on the standard or regulation considered. The difference in the impact of standards and regulations on US and Japanese FDI may be explained by the fact that FDI from the two countries go in different specific sectors and that different sectors have varying degrees of sensitivities to different labor market standards and regulations. The bulk of Japanese non-manufacturing FDI goes into service (professional, scientific, technical, information services) (31%), real estate (27%), and finance<sup>23</sup> and insurance (18%), while majority of US non-manufacturing FDI goes into finance<sup>24</sup> (45%), petroleum (16%), and wholesale trade (14%). Greater proportion of Japanese manufacturing FDI goes into electrical (38%), chemical (15%), and transport (11%), while majority of US manufacturing FDI goes into chemical (33%), machinery (17%), and transport (16%).<sup>25</sup>

<sup>23</sup> Including banking institutions

<sup>24</sup> Excluding banking institutions

<sup>25</sup> These figures are based on average US and Japanese outbound FDI from 1990-2003.

## VI. Robustness Check

Several robustness checks were performed to verify the results in the preceding section. These estimations are displayed in Tables 4-6.

Table 4. Robustness Check – Coefficients of Wage and Wage<sup>2</sup> Excluding LMF Indicators

Panel A. Without LMF, FE			
	All Countries	Developed Countries	Developing Countries
Wage	0.0056 (0.048)	0.2478* (0.147)	-0.0196 (0.053)
(Wage) <sup>2</sup>	0.0029 (0.003)	-0.0121 (0.010)	0.0044 (0.003)
Panel B. Without LMF, OLS			
	All Countries	Developed Countries	Developing Countries
Wage	0.0624** (0.023)	0.1203* (0.066)	0.0644** (0.024)
(Wage) <sup>2</sup>	-0.0032* (0.001)	0.0042 (0.007)	-0.0040** (0.001)

Notes: Values in ( ) are standards errors. \*\* and \* indicate significance at 5% and 10% level, respectively. The same explanatory variables that appear in Appendix Table 7 are used in the estimations, but are not shown for brevity purposes.

First, though the correlation between wage and the different labor market flexibility indicators do not suggest a high level of correlation as seen in Appendix Table 8, I recognize the possibility that the labor market indicators may just be capturing the effect of wages or vice-versa. Table 4 contains the coefficients of wage and wage<sup>2</sup> in estimations excluding any labor market flexibility indicator. Coefficients in Panel A are estimated using fixed effects estimation, while coefficients in Panel B are estimated using ordinary least squares. These coefficients can then be compared to the coefficients of wage and wage<sup>2</sup> in Appendix Tables 7A and 7B, where labor market flexibility indicators are included in the estimations. The coefficients of wage and wage<sup>2</sup> displayed in Table 4, Panels A and B are similar to the

coefficients in Appendix Tables 7A and 7B, respectively.<sup>26</sup> This dismisses the possibility that the labor market flexibility indicators are capturing the effects of wages.

Notes: Values in ( ) are standards errors. \*\* and \* indicate significance at 5% and 10% level, respectively. The same explanatory variables that appear in Appendix Tables 7A and 7B are used in the estimations, but are not shown for brevity purposes.

Third, I divide the sample of countries into low and high rigidity countries. Countries with below average labor market indexes are considered to have less rigid labor markets,

<sup>27</sup> The only exception is that hiring standards loses significance in Table 5. This can be explained by the high correlation between hiring and at work standards as seen in Appendix Table 8.

while those with above average are considered to have more rigid labor markets. Results are shown in Table 6. Panel A, columns (1) and (2) reveal that countries classified under low rigidity will have increasing FDI inflows as hiring and at work standards increase. Firing standards are insignificant for low rigidity countries. Countries classified under high rigidity will have decreasing FDI inflows as hiring and firing standards increase, as seen in Panel A, columns (12) and (14). At work standards are insignificant for high rigidity countries. These suggest that countries with few labor market standards can still increase their standards and attract more FDI. However, for countries with already high labor market standards, increasing standards any further will deter FDI inflows. These confirm earlier results. Panel B shows that as hiring regulations increase in low rigidity countries, FDI inflows will decrease as seen in columns (6), but as work hour and firing regulations increase, FDI inflows will increase, as seen in columns (3) and (8), respectively. Meanwhile, as work hour regulations increase in high rigidity countries, FDI inflows will decrease as seen in column (15), but both hiring and firing regulations are insignificant as displayed in columns (10), (12), (14), and (16). Comparing these results to the developed and developing countries samples in Tables 1A and 1B shows no discernable pattern, suggesting that countries classified under low (high) rigidity countries are not necessarily developed (developing) countries.

Finally, I accounted for other market regulations that may be considered important by MNCs in choosing FDI host countries. In particular, I included variables that may capture the cost of market regulations, namely, the cost of starting a business, cost of registering a property, legal rights of a business, investor protection, and cost of implementing a contract.<sup>28</sup> Some of these variables are highly correlated with each other. For instance, investor

---

<sup>28</sup> These are from the Doing Business Survey of the World Bank.

protection is highly correlated with legal rights of a business, and cost of a contract is highly correlated with the cost of starting a business. Thus, I did not include highly correlated variables in a single estimation. Some of these variables are likewise highly correlated with the labor market flexibility indexes. For instance, legal rights of a business is highly correlated with the rigidity of employment index<sup>29</sup>, and investor protection is highly correlated with the rigidity of hours and difficulty of firing index<sup>30</sup>. In such cases, I excluded the market regulation that is highly correlated with a labor market flexibility indicator. Results show that the other market regulations are not statistically significant in explaining differences in FDI inflows to countries coming from the rest of the world. A possible explanation for this is that the variables considered are highly correlated with the real GDP per capita, which is already included in the estimations.<sup>31</sup>

## VII. Conclusion

This study has made a number of significant contributions to our understanding of the labor market flexibility–FDI inflows literature. First, using a simple model, this study was able to reconcile the contrasting findings of previous studies. On the one hand, labor market regulations and standards decrease FDI inflows through the cost channel by increasing the total variable cost faced by a firm when it needs to make an adjustment in its employment level due to market uncertainties. On the other hand, labor market regulations and standards increase FDI inflows through the productivity channel by decreasing the marginal cost of production faced by a firm.

---

<sup>29</sup> Countries with high degree of legal rights have low rigidity of employment index.

<sup>30</sup> Countries with high degree of investor protection have low rigidity of hours and difficulty of firing indexes.

<sup>31</sup> Average correlation coefficient between GDP per capita and various regulations is 0.50.

Second, in contrast to existing studies that have assumed a simple linear relationship, this study has shown that it is important to account for non-linear relationship between labor market flexibility and FDI inflows. Allowing for a non-linear relationship revealed that some degree of labor market standards and regulations may be attractive for foreign investors as this may signal better labor relations and higher labor productivity. There is evidence that the negative impact of some labor market standards and regulations may only manifest itself at higher levels of standards and regulations. This result is important especially for developing countries that want to attract more FDI inflows. In particular, there is no solid evidence that developing countries should “race to the bottom” in order to attract more FDI. What is needed is a proper balance of labor market regulations that will enhance labor productivity, but at the same time will not be too costly from the point of view of MNCs.

Third, in contrast to previous studies that have used a single aggregated index, this study used disaggregated labor market indicators to investigate the FDI-labor market flexibility relationship. Results strongly suggest that it is important to disaggregate the different aspects of labor market standards and regulations as foreign investors respond differently to them.

Fourth, the use of ILO indexes as indicators of labor market standards and WB indexes as indicators of labor market regulations has shown that it is important to distinguish between labor market standards and regulations. In general, FDI inflows increase in countries with higher labor market standards, but decrease in countries with higher labor market regulations. These suggest that countries should be cautious in formulating regulations to implement standards. While the existence of labor market standards may be attractive to foreign investors as they signal higher labor productivity, the way they are implemented is likewise important, as they can be costly from the point of view of firms.

Finally, this study has shown that Japanese and US MNCs respond differently to labor market standards and regulations. In particular, Japanese MNCs are more sensitive to most labor market standards and regulations, such that FDI inflows from Japan decrease as labor market standards and regulations increase.

Appendix Table 1. ILO Conventions on  
Hiring, At Work, and Firing Standards

Standards	Convention No.
<i>Hiring</i>	
Minimum Age	138
Minimum Age (Industry)	59
Minimum Age (Non-Industrial Employment)	33
Minimum Age (Underground Work)	123
Part-Time Work	175
Minimum Wage Fixing	131
Minimum Wage Fixing (Agriculture)	99
Maintenance of Social Security Rights	157
Medical Care and Sickness Benefits	130
<i>At Work</i>	
Forty-Hour Week	47
Hours of Work (Commerce and Offices)	30
Hours of Work (Industry)	1
Weekly Rest (Commerce and Offices)	106
Weekly Rest (Industry)	14
Holidays with Pay	52,132
Holidays with Pay (Agriculture)	101
Paid Education Leave	140
Protection of Wages	95
Night Work	171
Night Work of Young Persons (Industry)	6, 90
Night Work of Young Persons (Non-Industrial Occupations)	79
Night Work (Women)	89
Employment Injury Benefits	121
Occupational Safety and Health	155
Occupational Health Services	161
Prevention of Major Industrial Accidents	174
Maternity Protection	103
Invalidity, Old-Age, and Survivors' Benefits	128
<i>Firing</i>	
Employment Promotion and Protection Against Unemployment	168
Protection of workers' Claims (Employer's Insolvency)	173
Termination of Employment	158
Unemployment Provision	44
Unemployment	2

Appendix Table 2. World Bank Labor Market Flexibility Indicators

*Difficulty of Hiring Index (DHI)*

- whether term contracts can be used only for temporary tasks
- maximum duration of term contracts
- ratio of mandated minimum wage to the average value added per worker

*Rigidity of Hours Index (RHI)*

- whether night work is unrestricted
- whether weekend work is allowed
- whether the workweek can consist of 5.5 days
- whether the workday can extend to 12 hours or more (including overtime)
- the annual paid vacation days are 21 or fewer

*Difficulty of Firing Index (DFI)*

- whether redundancy is not considered fair grounds for dismissal
- whether the employer needs to notify the labor union or the labor ministry to fire 1 redundant worker
- whether the employer needs to notify the labor union or the labor ministry for group dismissals
- whether the employer needs approval from the labor union or the labor ministry for firing 1 redundant worker
- whether the employer needs approval from the labor union or the labor ministry for group dismissals
- whether the law mandates training or replacement before dismissal
- whether priority rules apply for dismissals
- whether priority rules apply for reemployment

Appendix Table 3. Summary of Labor Market Indicators  
for Developed and Developing Countries

Countries	Developed Countries				Developing Countries			
With ILO Conventions	Hiring	At Work	Firing		Hiring	At Work	Firing	
Above the mean	69%	56%	71%		64%	40%	38%	
Below the mean	31%	44%	29%		36%	60%	62%	
With WB Indicators	REI	DHI	RHI	DFI	REI	DHI	RHI	DFI
Above the mean	46%	41%	68%	39%	51%	59%	33%	48%
Below the mean	54%	59%	32%	61%	49%	41%	64%	52%

Appendix Table 4. Labor Market Indicators in Developing Countries

Labor Market Indicator	Developing Country Dummy (=1)
ILO Indicators	
Hiring	-0.0475
At Work	-0.1692
Firing	-0.3990
WB Indicators	
Rigidity of Employment	0.1923
Difficulty of Hiring	0.1426
Rigidity of Hours	0.0303
Difficulty of Firing	0.1162

Appendix Table 5. Variable Description and Sources

Variable	Description	Source
FDI Inflows	Inflows of Foreign Direct Investment from the Rest of the World	www.unctad.org
Japanese FDI	Inflows of Foreign Direct Investment from Japan	http://www.mof.go.jp
US FDI	Inflows of Foreign Direct Investment from US	http://www.bea.gov/international
Wage	Monthly wage in US\$	www.ilo.org
GDP per capita	GDP per capita, PPP (constant 2000 international \$)	World Development Indicators
Inflation	Annual Inflation Rate	World Development Indicators
Trade	Trade in goods and services (% of GDP)	World Development Indicators
Tax	Taxes on goods and services (% of revenue)	World Development Indicators
Labor Force Participation	% of total population ages 15-64 in the labor force	World Development Indicators
Literacy Rate	Total adult literacy rate (% of people ages 15 and above)	www.unesco.org
Population	Population ages 15-64	World Development Indicators
Exchange Rate	Local Currency Unit per US\$, period average	World Development Indicators
External Debt	External debt (% of GDP)	World Development Indicators
Corruption Index	Index ranges from -2.5 to 2.5, with -2.5 and 2.5 indicating the least and most corrupt government	World Governance Indicators
Capital Openness Index	Index ranges from 0-1, with 0 and 1 indicating the most and least capital account restrictions, respectively,	Chinn and Ito (2006)
Manufacturing Value-Added	Manufacturing, value added (constant 2000 US\$)	World Development Indicators
Distance from US	Great circle distance between Washington DC, USA and Country's Capital (km)	http://www.indo.com/distance/
Distance from Japan	Great circle distance between Tokyo, Japan and Country's Capital (km)	http://www.indo.com/distance/
Dummy for Democratic Country	Dummy=1 if democratic country; 0, otherwise	World Factbook
Dummies for Preferential Trading Agreement	Dummy=1 if member of PTA; 0, otherwise (PTAs considered are AFTA, NAFTA, EU, MERCOSUR, CARICOM, COMESA)	www.wto.org

Appendix Table 6. Summary Statistics

Variable	Mean	Standard Deviation	Minimum Value	Maximum Value
FDI Inflows (% of GDP)	6.92	38.88	0	523.37
Japanese FDI, Total (in log)	1.53	2.51	0	10.55
Japanese FDI, Manufacturing (in log)	0.58	1.71	0	9.16
Japanese FDI, Non-Manufacturing	0.59	1.74	0	10.25
US FDI, Total (in log)	8.99	0.47	7.72	9.70
US FDI, Manufacturing (in log)	1.01	1.61	0	5.13
US FDI, Non-Manufacturing (in log)	0.97	1.55	0	4.59
Wage (in log)	5.93	1.83	0	14.79
Hiring Index	18.17	14.77	0	66.67
At Work Index	19.58	15.63	0	66.67
Firing Index	13.24	19.34	0	100
Rigidity of Employment	34.03	17.88	0	74
Difficulty of Hiring	31.88	26.55	0	100
Rigidity of Hours	39.15	22.28	0	80
Difficulty of Firing	31.09	21.80	0	80
GDP per capita	7933	8804	170.55	53582
Inflation	57.29	565.42	0	23773
Trade (% of GDP)	85.28	50.55	10.83	456.08
Taxes on Goods and Services (% of GDP)	29.28	12.79	0.69	79.45
Labor Force Participation Rate	69.73	8.91	46.07	93.12
Literacy Rate	78.36	22.05	11.40	100
Population (in log)	15.62	1.94	10.59	20.98
Exchange Rate (in log)	3.00	3.07	-19.84	14.22
External Debt (% of GDP)	1.40	18.03	0	548.15
Corruption Index	-0.01	1.00	-2.09	2.49
Manufacturing Value-Added	20.87	2.79	11.62	28.15
Distance from US (in log)	8.99	0.47	7.72	9.70
Distance from Japan (in log)	9.16	0.42	7.05	9.82

## LABOR MARKET RIGIDITY AND FOREIGN DIRECT INVESTMENT: THE CASE OF EUROPE

MOGAB, John\*

KISHAN, Ruby

VACAFLORES, Diego E.

---

**Abstract:** This paper examines the relationship between labor market rigidity and FDI decisions by European multi-national firms during 2004-2008. We use firm-level data for European Multinational Enterprises investment in 41 European countries during these four years. Using conditional fixed effect logit and Tobit estimations, we show that European MNEs generally respond to regulatory, gravity and firm specific indicators in the expected ways, but their responses to changes in labor market institutions are less consistent. We also find that the relationship between MNEs location decision and host country's labor market institutional factors is sensitive to host country's development stage and market integration with the EU countries.

**Keywords:** Foreign Direct Investment; Labor Flexibility; Economic Integration; Trade and Labor Market Interactions.

**JEL classification:** F23; J80; F15; F16.

---

### 1. Introduction

The potential contribution of foreign direct investment (FDI)<sup>1</sup> to economic growth – with its introduction of new technology, capital accumulation, generation of jobs and access to new markets – has been extensively analyzed. Most studies have found that FDI exerts a positive effect on the growth rate of the receiving economy (i.e. Borensztein *et al.* (1998), De Mello (1999)), contributes in the generation of employment (Spiezia (2004), Vacaflores (2011)), and increases total tax revenues of the host country (Vacaflores (2009)). Consequently, many governments have developed policies to attract FDI. Many host countries have improved their macroeconomic environment and have also concentrated on upgrading specific policies, such as enhancing property rights, opening previously protected markets (especially government procurements), providing firm specific subsidies, and lowering tax rates to attract FDI.

The globalization of production processes by multinational enterprises (MNEs) has further encouraged policymakers around the world to redesign their labor market regulations to provide greater flexibility to the operations of MNEs. The rationale is that increased flexibility in labor market regulations will make a host country more attractive to MNEs looking at alternative locations and will result in greater FDI. Indeed, recent studies by Javorcik and Spatareanu (2005), Delbecque, Méjean, and Patureau (2007) and others have shown that labor market rigidities are negatively related to MNE's location decisions and the amount of FDI inflows.

<sup>1</sup> FDI refers to ownership and control of productive assets, such as factories, mines or infrastructure, by a parent enterprise of a foreign affiliate.

However, while studies analyzing the impact of labor market institutions on FDI have provided evidence that greater labor market flexibility affects MNEs' location decisions and the amount of FDI, the impacts across time, regions, and levels of development have been relatively neglected. Changing conditions over time may make specific determinants more relevant in certain years than in others, perhaps bearing a differential effect according to the economic conditions of a given period. In addition, labor market flexibility could also have a differential effect on the location of FDI according to regions or types of countries if host country characteristics are inherently different. Investing in a European Union (EU) country may provide MNEs more certainty in regulatory enforcement and access to a broader market, as well as greater demand for its products. Transition economies, on the other hand, may be enticing as low-cost production platforms, but may also be detrimental for the lack of purchasing power of their populations, leading to different motivations for MNEs to invest in these countries than in the more established markets.

In this study we examine the effects of labor market rigidity on FDI using data on European firms' foreign investment within Europe over the period 2004-2008. We extend the framework utilized by Javorcik and Spatareanu (2005), where a set of host country characteristics and labor market indicators are used to estimate the location decisions of MNEs and amount of FDI, and to examine if the effects of the labor market indicators are stable across time and across different host country classifications. The data allow us to construct the decision variable in terms of a dichotomous variable to reflect FDI participation, and in terms of the stock of FDI in a given host country in four cross-sections to test the stability of the effects of labor regulations on FDI. Focusing on Europe also enables us to test the effects across different country classifications (i.e., EU versus non-EU and transition versus non-transition economies). This is important because FDI decisions are impacted by the characteristics of the host country according to the specific economic circumstances of the period and the perceived risks and rewards of the country or region.

We focus on the influence of three labor market indicators: the rigidity of hours' index, the firing costs, and the difficulty of hiring index. We find that the effect of the first two are in accordance with conventional wisdom when all countries are analyzed together, but when controlling for country classification we find evidence of a differential effect in some years. The evidence on the effect of the difficulty of hiring index is consistent in some years with previous studies only after accounting for inherent characteristics of the host country. We find that most of the so-called gravity determinants (e.g., size of market) of FDI are as expected and stable across time, with the exception of corporate tax rates.

The remainder of the article is organized as follows. Section 2 describes the literature on the impact of labor regulations on FDI. Section 3 lays out the data and the methodology. Section 4 presents the results, and Section 5 concludes.

## **2. Literature Review**

Globalization increasingly has wide-ranging impacts on almost every aspect of the production process and multinational corporations are adapting by expanding their

Mogab, J., Kishan, R., Vacaflores, D.E. *Labor Market Rigidity and FDI: The Case of Europe*

operations across borders. Host countries actively compete to attract MNEs, enacting policies to facilitate trade, providing firm specific incentives, and increasing the flexibility of some regulations. One factor that may help countries differentiate themselves from alternative potential destinations is the degree to which their labor markets are regulated.

Research on this topic has been facilitated in recent years by the development of indices measuring various aspects of labor market regulation by Botero *et al.* (2004), the World Bank and World Economic Forum. The initial theoretical basis for the impact of labor market institutions on inward FDI is provided by Haaland and Wooton (2002). Their theoretical model focuses on uncertainty in the marketplace that forces firms to take into account the risk of having to close a foreign subsidiary. The model hypothesizes that, other things equal, a flexible labor market with limited lay-off rules and low closure costs will be more attractive to inward FDI. Haaland *et al.* (2003) extend the analysis to take into account not only exit costs, but also entry costs. They also show theoretically that worker protection rules will deter inward FDI. They find empirical support for their predictions in an analysis of FDI in Bulgaria, Romania and Poland by western MNEs during 1994-97.

Görg (2005) finds further empirical evidence in support of the Haaland and Wooton, and Haaland *et al.* hypotheses. Görg utilizes a labor market index of hiring and firing restrictions based on surveys of managers conducted by the World Economic Forum. Using aggregate data on U.S. FDI to 33 developed and developing countries during 1986-96, he finds a statistically significant negative relationship between U.S. FDI in manufacturing and labor market restrictions. Javorcik and Spatareanu (2005) also look at the impact of labor market rigidity on FDI utilizing firm-level data of new investments across 19 European countries during 1998-2001. The indices of labor market rigidity reflect laws governing individual and collective dismissals, length of the dismissal notice period, and the required severance payment. Their results suggest that greater flexibility in the host country's labor market relative to that in the investor's home country is associated with larger FDI inflows.

Dewit, Görg and Montagna (2009) further extend the theoretical model to not only include the impact of labor markets on inward FDI, but also on outward FDI (what they call “domestic anchorage”). They test the effects of employment protection differentials between domestic and foreign locations on the investment decision of MNEs in OECD countries during 1986-95. The index of employment protection for each country is based on measures of protection affecting the country's temporary and regular employment and they use bilateral FDI flows from the OECD's *International Investment Statistic Yearbook*. Their study finds that for a given level of home country employment protection, higher levels of employment protection in the host country discourage home country firms from investing there. In addition, they also find that a high level of employment protection in the home country discourages outward FDI.

In a study incorporating Krugman's international trade theory and labor market literature, Delbecque *et al.* (2007) analyze French firms' expansion decisions abroad during 1992-2001. Their empirical analysis utilized firm-level data to estimate the

impact of labor market institutions on the firms' location decisions. Their results suggest that stringent employment protection laws, powerful trade unions and a more centralized wage-bargaining process negatively impacted French firms' location decisions.

The most recent study, Olney (2011), is based on U.S. outward investment to 26 OECD countries during 1985-2003. It not only confirms the negative relationship between labor market rigidities (i.e., employment protection rules) and FDI, but also finds evidence that the effect differs by type of FDI. His results suggest that employment protection legislation in the host country has a limited impact when a firm invests in a country to access that foreign market (horizontal FDI). There is a more substantial negative impact when a MNE accesses a foreign market by setting up an affiliate in a neighboring country and exporting to the desired country (export-platform FDI), but the largest negative impact occurs when MNEs invest in a country in order to take advantage of low foreign factor prices and to minimize costs (vertical FDI).

There are, however, at least two studies that failed to consistently find the expected negative effects of labor market rigidity on the decision to invest in a given host country. In a study of FDI from seven developed countries entering seven Central and Eastern European countries using country-level data, Leibrecht and Scharler (2009) find that differences in employment protection legislation have no effect on FDI flows entering the host countries when labor costs are included in the model. However, they do find a statistically significant effect – although weak – when they drop labor costs, concluding that labor costs are already capturing information from the labor market, thus rendering the effect of labor rigidity on FDI into these transition economies insignificant when entered together. Parcon (2008) hypothesizes a non-linear relationship between labor market institutions and FDI inflow. Utilizing ILO labor market standards, as well as the World Bank's labor market regulatory indicators, Parcon analyses FDI inflows to 195 countries during 1990-2005 and finds evidence that FDI to developed and developing countries is affected differently (negatively in some cases and positively in other cases) by different aspects of labor market standards and regulations.

This study is similar to the above studies in analyzing the relationship between FDI and labor market institutions, and can be viewed as updating them in the sense that the time period covered herein is more recent. But, importantly, this study differs in several ways. Our analysis is based on a more extensive firm-level dataset than the previous studies utilizing firm-level data. Unlike all the previous studies, this study includes four cross-sections over time rather than a single cross section. The multiple cross-sections allow for changes in the labor market indices and, thus, allow us to analyze the stability of the parameters over time.

### 3. Data and Methodology

Our analysis examines the impact of labor market rigidity on MNEs location decisions and the amount of FDI in 40 European countries during 2005-08. To analyze the location decisions of the MNEs, we utilize a fixed effects logistic regression. For a given time period  $t$ , we specify this decision in the equation

$$FDI_{ij} = \alpha + \kappa * FDII_j + \phi * GI_j + \varphi * LMI_j + \varepsilon_{ij} \quad (1)$$

Mogab, J., Kishan, R., Vacaflores, D.E. *Labor Market Rigidity and FDI: The Case of Europe*

where  $FDI_{ij} = 1$  if firm  $i$  conducts FDI in country  $j$ ,  $FDI_{ij} = 0$  otherwise. This decision is a function of FDI regulatory indicators in the host country ( $FDII_j$ ), gravity indicators of the host country ( $GI_j$ ), and labor market indicators of the host country ( $LMI_j$ ), all entering our specification with a lag. The parameter  $\alpha$  is the firm specific fixed effect, which controls for unobservable firm characteristics, and  $\varepsilon_{ij}$  is the error term. Each firm has the possibility to invest in 40 host countries in a given time period, so for each firm the number of observations is equal to the number of all possible destination countries under consideration.

The data on FDI and firm specific variables are derived from the OSIRIS database compiled by Bureau Van Dijk. Osiris provides company-level information on 65 million companies worldwide, including information on global ownership from which FDI is derived. We have extracted information on the investment decisions of all European firms with subsidiaries in other European countries. We first determine the MNE's ownership of a given subsidiary by multiplying the MNE's percentage ownership of the subsidiary by the total assets of the subsidiary. If an MNE owns more than one subsidiary in a country, those totals are added to determine the total stock of a MNE's FDI in each destination country.<sup>2</sup> For the analysis of MNE's location decisions, the information collected on FDI allows us to create a dichotomous measure that takes the value of one if the MNE of a given country invests in one of the other countries of Europe, and zero otherwise. The measure includes new and established subsidiaries. While previous studies have concentrated on the determinants of new FDI only, our examination of the stability of these effects over time forces us to include existing FDI to avoid survival bias.

The independent variables are entered in the models with a lag, not only to reflect the fact that investment decisions are taken in advance, but also to avoid potential reverse causality between FDI and the determinants. We include the so-called gravity variables of population, real GDP per capita, average wage, and geographic proximity incorporated in many of the earlier studies. The first measure is typically considered a proxy for the size of the market, and the second variable is a proxy for the purchasing power in the host country. Both measures are from the World Development Indicators (World Bank) and are particularly important if the FDI is geared to satisfying demand in the home market (horizontal FDI). The average wage, a measure of one aspect of the total cost of labor, is from Eurostat<sup>3</sup> expressed in real terms. Geographic proximity a dichotomous variable that indicates the home and host countries share a common border, a proxy for cultural affinity. Since FDI is influenced by the rules and regulation of the host country ( $FDII_j$ ), we include three measures of the regulatory environment in the host country, including corporate taxation, FDI rules

---

<sup>2</sup> We then calculate total real FDI by dividing the stock of FDI by the CPI.

<sup>3</sup> In some cases the data were not available from Eurostat and, in those cases the data is from the country's Central Bank or statistical offices.

and property rights protection. The tax obligations in the host country are measured as the average statutory tax rate on profits of MNEs,<sup>4</sup> and are taken from Doing Business (World Bank). The security of MNEs' investment is measured by the Global Competitiveness Report's indices on property rights protection and rules governing FDI (indices range from 1 to 7). The indices increase as the security for MNE's investments improves.

Lastly, we include three indices of labor market institutions ( $LMI_j$ ) from the Doing Business publication: the rigidity of working hours, the difficulty of firing, and difficulty of hiring in the host country. The rigidity of hours index and the difficulty of hiring index are measures scaled from 0 to 100, with the indexes increasing if they become more rigid. The cost of firing an employee is measured in terms of weeks of compensation. These measures reflect labor market flexibility in the main dimensions in which the literature has focused, and are similar to the measures in Javorcik and Spatareanu (2005). We expect that an increase in the difficulty of hiring index, in the rigidity of hours index, or in the firing costs in a country would lead to a decrease in MNEs investing in that country.

In addition to examining the location decision of a MNE, we also explore the effects of the labor market indicators on the amount of investment that European MNEs made in other European countries during 2005-08. Using the Tobit model, we estimate the following equation for the volume of investment

$$\ln(FDI_{ij} + 1) = \alpha + \gamma * X_i + \beta * FDI_j + \delta * GI_j + \lambda * LMI_j + \varepsilon_{ij} \quad (2)$$

where the dependent variable is the logarithm of the size of real foreign direct investment made by firm  $i$  in country  $j$ . Following Javorcik and Spatareanu (2005), we take the log of one plus the volume of FDI because the volume of FDI equals zero in the potential destinations in which a given MNE does not operate.  $X_i$  denotes firm specific and home country specific variables. We include real total assets and international experience of a MNE as firm specific variables. Real total assets measures the size of a MNE, whereas the number of foreign subsidiaries of a MNE is used to proxy its international experience. The expectation is that the size of FDI should increase as a firm gets larger or acquires more international experience. We include home country GDP per-capita, and population to control for purchasing power and market size of the home country. It is expected that the volume of a MNE's FDI should increase as its home country gets richer since most MNEs are headquartered in the high-income countries. The other variables are the same as in the previous model. Both models use logs of real GDP per capita, population, wages, and total assets.

Panel A in Table 1 presents descriptive statistics of the variables included in our model for all European countries considered in our study. As can be observed, the rules on FDI and the protection of property rights became slightly more encouraging for MNEs between 2005 and 2008, and the level of taxes as a share of commercial profits decreased. We also see that average real wages increased in Europe by approximately 40% during this time period, real GDP per capita increased by

---

<sup>4</sup> The statutory tax rate is not necessarily the effective tax rate that a MNE may pay.

Mogab, J., Kishan, R., Vacaflores, D.E. *Labor Market Rigidity and FDI: The Case of Europe*

approximately 13%, but population remained relative stable. As far as labor market conditions are concerned, average firing cost seems to be fairly constant overtime, whereas, average values of difficulty of hiring workers and rigidity of hours indices show significant variation. Both of these measures indicate that labor markets on average became more rigid in 2006, and less rigid in following years. It should also be noted that there is significant variation in the labor market indicators across destination countries in a given time period (reflected in the standard deviation). Also, the variation in the firing costs and difficulty of hiring indices across countries is considerably greater than the variation in the rigidity of hours index.

	2005	2006	2007	2008
Rules on FDI (1 – 7)	4.913 (.607)	5.152 (.831)	5.241 (.791)	5.211 (.800)

Note: standard deviations in parenthesis

To explore whether labor market conditions differ between (a) transition and non-transition economies within Europe, and (b) EU and non-EU countries, Panels B and C of Table 1 present labor market descriptive statistics for these categories.<sup>5</sup> A few differences are noteworthy. Firing costs are consistently higher in non-transition economies and in non-EU countries relative to their counter category. Variation in firing costs across non-transition economies is more than double the variation in firing costs in transition economies for each year studied. The rigidity of hours index and difficulty of hiring index also consistently differ between transition and non-transition economies, but this difference is not consistent across years. The same pattern holds for EU versus non-EU countries.

#### 4. Results

The results of the decision to invest abroad are presented in three parts: the first contemplating the importance of the measures of labor market flexibility of potential host countries on the decision to enter and remain in a host country, the second incorporating the importance of these labor conditions on the amount of FDI that MNEs made in the host countries, and the third explores the effect that labor market flexibility has on FDI according to country classification of the host country (transition versus non-transition economy) and the connectedness of the host country with the rest of the region (i.e., European Union membership).

Table 2, Panel A, presents the results of the conditional logit for the each of the years between 2005 and 2008. Because the interpretation of the coefficients of a logit regression is not straightforward, we report the odds ratio instead.<sup>6</sup> Of interest to us, the odd ratio  $\exp(\varphi)$  indicates whether changes in labor market rigidity increase or

<sup>5</sup> See Appendix Table A2 for list of countries in each category.

<sup>6</sup> The interpretation of this odds ratio is such that a one unit increase in the predictor would lead to an increase in the probability of investing abroad when the odds ratio is greater than one, compared to the default of not investing abroad. Alternatively, when the odds ratio is less than one, a one-unit increase in the predictor would lead to a decreased probability of investing abroad.

Mogab, J., Kishan, R., Vacaflores, D.E. *Labor Market Rigidity and FDI: The Case of Europe*

decrease the probability of a multinational firm choosing to invest in a given foreign country,  $j$ , relative to abstaining from investing in that country.

In terms of the regulatory variables that influence the decision to invest abroad by a MNE, the results indicate that host countries with rules that provide greater protection of FDI have a higher probability of attracting MNEs investment, and it is statistically significant at the one percent level. The results also show that an increase in the protection of property rights in the host country in 2005, 2006 and 2008 led to a higher probability that MNEs would invest in the host country, also statistically significant at the 1 percent level. In 2007, however, the effect of increased property rights protection resulted in a statistically significant lower probability of MNEs investing in a country. The estimate for the measure of the tax rate on profits indicates that an increase in the tax rate in the host country increases the probability of having MNEs entering or operating in their country, which is also statistically significant at the 1 percent level. While the first two regulatory variables largely have expected effect on FDI, the effect of corporate tax rates is counterintuitive.

The results of our second set of explanatory variables, the gravity measures that influence FDI decisions, show the expected impact on the decisions to invest abroad in all cases except one, and are statistically significant at the 1 percent level. Table 2, Panel A indicates that an increase in the average wage in the host country is associated with a statistically significant lower probability of MNEs investing in that country in three of the four years. This negative relationship is consistent with the MNE objective of internationally rationalizing the production process. In 2007, however, we find an unexpected result when a higher average wage rate in the host country led to a statistically significant higher probability of FDI. For the remaining gravity variables the results are as expected. An increase in the GDP per capita in the host country (a proxy for the wealth and purchasing power of its population) led to a higher probability that MNEs will enter and operate in the host country, indicating that foreign investment may be geared to satisfying local demand. In terms of the size of the market, we also find that host countries with larger populations are associated with a higher likelihood of having foreign companies investing in their countries, which reinforces the view that FDI in Europe seems to be somewhat oriented toward satisfying the local demand. These results suggest that the MNE's were engaged in both vertical FDI (i.e., seeking low-cost production platforms) and horizontal FDI (seeking markets in the wealthier countries with high income). The last indicator in this set reveals that host countries that share borders with the country where the MNE is headquartered had a statistically significant higher probability of attracting MNEs to their countries in each of the four years.

The results of the effects of labor market flexibility on potential host countries attracting FDI are consistent with expectations for two of the three variables. An increase in the rigidity of hours index represents less flexibility in the amount and scheduling of working hours. The results indicate a negative relationship, i.e., as host countries allow MNEs more flexibility the probability of attracting FDI increases, which is statistically significant at 5 percent or better. In terms of the influence of firing costs on the attraction of FDI, the results show that an increase in the number of weeks required to be paid in a severance package (an increase in firing costs) generally led to a lower probability of FDI in the host country, which is statistically significant at the 1 percent level. Both these measure behave as expected because more flexible work hours and smaller cessation costs allow MNEs to reshape labor inputs at lower costs in response to changing market conditions. Examining the effects of the difficulty in

Mogab, J., Kishan, R., Vacaflores, D.E. *Labor Market Rigidity and FDI: The Case of Europe*

hiring workers on FDI, however, we find that a less flexible environment for hiring workers (an increase in the difficulty of hiring index) increased the probability that MNEs would enter and operate in the host country, which is counterintuitive to what one would expect. These findings are statistically significant at the one percent level for three of the four years.

We next turn to the empirical testing of the effects of the regulatory environment, gravity variables, and labor market flexibility on the amount of FDI during 2005-08. Table 2, Panel B presents the evidence on the amount of FDI undertaken by MNEs using the Tobit model in Equation 2 above. The effect of each variable on the amount of FDI is highly consistent with the finding regarding MNE's location decisions for FDI. The host country gravity variables, including GDP per capita, average wage rate, population and geographic proximity, all exhibit the expected signs and are statistically significant at the one percent level for each year.<sup>7</sup> Similarly, the regulatory variables rules on FDI and property rights have the expected signs and are statistically significant at the one percent level for almost all years.<sup>8</sup> The labor market flexibility variables, rigidity of hours index and firing cost indices, as expected, have statistically significant negative effects on the volume of FDI. In this model, we again find counterintuitive effects for corporate tax rate and difficulty of hiring that are statistically significant at the one percent level (except for difficulty of hiring in 2007). The Tobit specification provides some additional insights into the impact of investor characteristics (size and international experience of the MNE) on FDI. Not surprisingly, we find that the volume of FDI rises as the size of the MNE and its international experience grows (statistically significantly each year at the one percent level). The model also includes characteristics of the MNE's home country (GDP per capita and population). The expected positive relationships are supported and are statistically significant at the one percent level.

In summary, Table 2 provides evidence that host countries with regulatory environments more favorable toward investors, larger and wealthier domestic markets, lower labor cost, and more flexible labor markets have an advantage over other countries in attracting FDI. These results are consistent with previous findings (Javorcik and Spatareanu (2005), Delbecque *et al.* (2007), Olney (2011), Parcon (2008)). We do find two unexpected results – the effects of corporate profit tax and difficulty of hiring index. The results for the corporate profit tax rate may be explained by considering what is included and what is not taken into account in the total tax rate measure. The total tax rate measures the amount of taxes payable by a business after accounting for deductions and exemptions, expressed as a share of commercial profits, including profit or corporate income tax, social contributions and other labor taxes paid by the employer, property taxes, turnover taxes and other taxes, such as municipal fees and vehicle and fuel taxes (Doing Business, 2006, p. 71). It does not take into account preferential tax treatment that host countries often extend to MNEs on a case-by-case basis, or tax treatment and accounting allowed by home country regulations. Investment incentives, in the form of tax abatements, have increasingly become an important tool in the competition among countries to attract FDI. Such incentive,

---

<sup>7</sup> With the exception that average wage rate for 2007 was not statistically significant.

<sup>8</sup> With the exception that property rights for 2007 was not statistically significant.

however, are not statutory and, thus, would not be reflected in the tax measure, but certainly may influence the location decisions of MNEs and the amount of FDI. There are also issues of double taxation in home and host country, and the potential for transfer pricing to shift profits and minimize taxation that can impact MNEs response to changes in corporate taxation (Blonigen (2005)). The unexpected results for the difficulty of hiring index are not easily explained, especially since the other two labor market flexibility measures were largely consistent with expectations across the years in both models. The difficulty of hiring index measures the applicability and duration of fixed-term contracts and the ratio of the country's minimum wage to the average value added per worker. While this measures a somewhat different aspect of labor markets flexibility than the rigidity of hours index and firing cost, it is not readily apparent why it would have an opposite effect on FDI.

While some studies (Delbecque *et al.* (2007), Görg (2005)) have utilized the levels of the gravity variables and labor market indicators as regressors, other studies have used the difference of the labor market indicator in the home country and that of the host country (Dewit *et al.* (2009), Javorcik and Spatareanu (2005)). We, thus, examine the relationships between MNEs' decision to invest and differences in corporate tax rates, average wage rate, and the labor market indicators in the home country and host country.<sup>9</sup> The results, in Table 3 below, indicate that all non-labor market variables, with the exception of differences in average corporate profit tax rates, have the expected signs and are statistically significant at 5% or higher. With respect to the relative labor market conditions, we find that host country rigidity of hours index and firing cost relative to the home country are generally significantly negatively related to FDI. We again, however, get counterintuitive results for the difficulty of hiring index. Thus, in general, the results are very similar to those presented in Table 2.

Since Panels B and C of Table 1 show significant differences in the labor market characteristics of different types of European economies, it is possible that grouping all the European countries together is somehow inexplicably influencing the results on the difficulty of hiring. To further investigate the relationships between labor market rigidities and FDI, we now introduce two alternative controls to try to unveil possible explanations for the unexpected results. We take into consideration that the investment decision of MNEs could be different according to the characteristics and the integration of the market in which they are investing. Since the breakup of the Soviet bloc, many European nations have been in various stages of restructuring their economic and political institutions. The same argument can be raised when the potential destination is a European Union (EU) country, since investing in an EU country involves access to the remaining countries of the EU, abiding by supranational rules and regulation, etc.

In order to examine the behavior of MNEs with regards to the restructuring of potential host countries, we create a dummy variable that takes the value of 1 when the destination country is a transition economy, and zero otherwise. Since our interest is in determining if labor flexibility can have a differential effect on FDI depending on the characteristics of the host countries we only interact our dummy variable with the labor

---

<sup>9</sup> The difference in each variable is calculated as the level in the home country minus the level in the host country.

Mogab, J., Kishan, R., Vacaflores, D.E. *Labor Market Rigidity and FDI: The Case of Europe*

market indicators. The results are presented below in Table 4 for both the logit (Panel A) and Tobit (Panel B) models. As the table shows, the transition dummy is statistically significant in all four cross sections, and indicates a preference towards higher investment in this set of countries starting in 2006, and becoming increasingly stronger through 2008.

The effects of the regulatory indicators on FDI are, in general, very similar to our baseline specification in both models, and also for the investor characteristics in the Tobit model. With respect to the host population and neighboring variables, the results are very similar to the findings for all the European countries. We find, however, that once we control for transition economies, the effects of wages on the location and amount of FDI become tilted towards investing in countries with higher wages – in three of the four years. Higher average wage rates indicate greater purchasing power for workers and may also be a reflection of higher labor productivity. Looking at the results of the effects of host country GDP per capita on FDI, we find the previously consistent positive effect is now negative for 2007 and 2008. Taken together these results suggest that MNEs were giving preference to investing in European countries with higher levels of labor productivity during 2006-08.

In terms of the labor market indicators, Table 4 shows that there are substantial differences between the effects of labor market flexibility on FDI in transitional versus non-transitional economies. For example, a more flexible environment in terms of determination of working hours in non-transition economies continues to be associated with a higher probability of investing in those host economies, and is statistically significant at the 1 percent level. In the case of a transition economy, the results indicate that this negative relationship holds only for 2006 and 2008. In 2005 and 2007, an increase in the rigidity of working hours in the transition economies increased the probability of investing in the country and increased the amount of FDI. We also find that increases in the cost of dismissing workers in non-transition economies results in a higher probability of MNE investment in these host countries for three of the four years. This effect is not in agreement with our previous results – nor with the expected outcome – but is statistically significant. The effect of higher firing costs in transition economies, however, reduces the probability of MNEs entering and investing in these countries, an effect that is statistically significant at the one percent level. Thus, the expected negative relationship between firing costs and FDI holds for transition economies, but not for non-transition economies.

The response of FDI to changes in the difficulty of hiring index also corroborates a differential effect of this labor market indicator on the decision to invest in a host country and on the amount of FDI entering these host countries. Our results consistently indicate an increase in the rigidity of hiring in non-transition economies increases the probability of MNEs investing in the non-transition countries (statistically significant at the 1 percent level). In the case of the transition economies, however, we find some statistically significant evidence of a negative relationship between the difficulty of hiring index and the probability of MNEs investing.

For the location decision, the logit model indicates a statistically significant positive relationship two years and a statistically significant negative relationship during 2008. In the Tobit model, the amount of investment in transition economies is significantly negatively related to the difficulty of hiring index during two years, and significantly positively related in only one year. Thus, we find statistically significant differences between the transition and non-transition economies and at least some evidence that the unexpected results on the difficulty of hiring index in our previous model may be driven by broader characteristics of the country rather than by the specific labor market institutions.

We further explore this potential differential effect of labor market rigidities on FDI by incorporating an indicator on European Union membership. We create a dummy variable that takes the value of 1 when the destination country is a European Union (EU) member, and zero otherwise (see Appendix Table A2 for the list countries in each classification). The results are presented in Table 5 for both the logit (Panel A) and the Tobit (Panels B) models. It can be observed that the relationship between the regulatory, gravity and investor characteristic variables and FDI are similar to those presented in Table 2, so we concentrate here on the effects of the labor market indicators and their interactions with the dummy variable. Not surprisingly, the results indicate that the investment decisions of European MNEs have been biased towards investing in EU members, with all estimates of the dummy variable producing a positive influence of EU membership on the attraction of FDI, although the effect is statistically significant in only two years.

In terms of the impact of the rigidity of hours' index on the decision to invest in a given country, Table 5 shows that greater rigidity in working hours is generally associated with a lower probability to invest in non-EU economies (statistically significant in each year except 2007 in both models). In the case of foreign investment going to EU countries, we find a negative relationship in three years and a marginally positive effect only in 2008 in both models. With respect to the cost of dismissing workers, the results indicate that an increase in the cost of firing workers consistently led to a lower probability of MNEs investing in non-EU economies, an effect that is in accord with the conventional wisdom and statistically significant. Furthermore, for FDI going into EU countries we find the effect of firing costs on FDI remains negative and statistically significant for two of the four years, but positive and statistically significant in 2006 in both models.

The results on the effects of the difficulty of hiring index on FDI are also insightful. Table 5 shows that a more rigid environment in terms of hiring workers is associated with a higher probability of MNEs investing in non-EU countries, which remains counterintuitive and is still statistically significant. For the EU countries, we find a very different set of results. The only year for which there is a statistically significant result is 2007 and the relationship is negative. While this is consistent with expectations, it is the opposite of the relationship for non-EU countries and of the results in Table 2. Thus, it seems clear that the unexpected results on the difficulty of hiring index found earlier are being driven by the FDI going to non-transition or non-EU countries.

## 5. Summary and Conclusions

The decision to invest abroad by MNEs usually emanates from the desire to enter a foreign market when trade barriers are significant (horizontal FDI) or from the search for lower-cost production platforms (vertical FDI). This study of European FDI analyzes the effects of labor market institutions on FDI, controlling for regulatory frameworks that entice and protect foreign investment (rules on FDI, protection of property rights, and tax obligations), the gravity variables (wage rates, the GDP per capita, population, and proximity to the MNE headquarters), and the special characteristics of the MNE (size, international experience, and home characteristics).

The findings suggest that European MNEs generally respond to the regulatory, gravity and firm specific indicators in the expected ways, but their responses to labor market institutions are less consistent.

Our results indicate that labor market institutions play an important role in the determination of the location and amount European MNEs invest in other European countries, but the positive relationship between markets with greater labor market flexibility and foreign investment does not necessarily hold for all labor market indicators, time frames, and types of host countries. The rigidity of working hours indicator is the most consistent of the labor market indicators examined and is largely consistent with the expected relationship throughout the period studied for all the countries taken together. But, we also find when controlling for country classification, FDI in the transition economies is unexpectedly positively related to the rigidity of hours index in two of the four years studied. Also for the firing cost index, unexpected findings show up in the non-transitional economies for three of the four years and in the EU countries in one year.

The findings on the effects of the difficulty of hiring index on FDI are the most contrary to expectations and previous studies. When taking all the European countries together, increased rigidity in labor market hiring consistently increased the probability of MNEs investing in the host country. When we control for country classification, we find some differences begin to emerge. There is some evidence that in transition and EU economies, MNEs responded in the expected manner to hiring rigidities. Our interpretation is that MNEs may have different objectives when investing (e.g., vertical versus horizontal FDI) in different countries and thus do not always respond to changes in labor market institutions in the same way. While these findings differ somewhat from earlier studies on FDI, they are supported by at least one study indicating that not all labor market regulations have the same effect on FDI flows to developed and developing countries (Parcon (2008)). These findings also suggest that, contrary to what has been viewed by many as a policy consensus, increased labor market flexibility may not attract more FDI in all countries.

## LABOR SUPPLY RESPONSE TO THE EARNED INCOME TAX CREDIT\*

NADA EISSA AND JEFFREY B. LIEBMAN

This paper examines the impact of the Tax Reform Act of 1986 (TRA86), which included an expansion of the earned income tax credit, on the labor force participation and hours of work of single women with children. We identify the impact of TRA86 by comparing the change in labor supply of single women with children to the change for single women without children. We find that between 1984–1986 and 1988–1990, single women with children increased their relative labor force participation by up to 2.8 percentage points. We observe no change in the relative hours worked by single women with children who were already in the labor force.

Historically, the United States has chosen to provide a safety net for families with children. Since 1935, Aid to Families with Dependent Children (AFDC) has supplied cash welfare payments to needy single-parent families. Families on AFDC may also receive food stamps, medicaid, and housing assistance. Because the maximum level of benefits is received by families with no income and because benefits are reduced almost dollar for dollar with additional earnings,<sup>1</sup> the welfare system is predicted by static labor supply theory to discourage the labor force participation and hours of work of single parents. Existing empirical evidence mostly confirms these theoretical predictions.<sup>2</sup>

In a series of major expansions beginning in 1987, the earned income tax credit (EITC) has emerged as a popular alternative method for transferring income to needy families with children. The EITC is a refundable credit; therefore, any credit due in excess of tax liability is refunded to the taxpayer in the form of a tax refund check. In 1996 when the most recent expansion of the EITC is scheduled to be fully phased in, the maximum credit will reach \$2206 for a taxpayer with one child and \$3644 for a tax-

payer with two or more children. Advocates of the EITC argue that the credit transfers income to a particularly deserving group of people, the working poor, and that the redistribution occurs with much less distortion of labor supply than is caused by other elements of the welfare system. In particular, the credit is said to encourage labor force participation.

The EITC creates a complicated and ambiguous set of labor supply incentives. Standard labor supply theory does indeed predict that the EITC will encourage labor force participation. This occurs because the EITC is available only to taxpayers with earned income. But theory also predicts that the credit reduces the number of hours worked by most eligible taxpayers already in the labor force. While the credit initially increases with income, producing offsetting income and substitution effects on hours worked, over 70 percent of recipients have incomes in regions in which the credit is constant (and therefore produces only a negative income effect on labor supply) or is being phased out (producing negative income and substitution effects). Moreover, since the phaseout of the credit produces a nonconvexity in the budget constraint, taxpayers with incomes beyond the phaseout region may choose to reduce their hours of work and take advantage of the credit. Cumulative marginal tax rates can be quite high in the phaseout region. In 1996 some taxpayers with two children and income between \$11,610 to \$28,495 will face a net marginal tax rate (on the worker's marginal revenue product) of 53 percent.<sup>3</sup>

In this paper we examine the impact of the Tax Reform Act of 1986 (TRA86), which included an expansion of the EITC, on labor force participation and hours of work. The expansion of the credit affects an easily identifiable group, single women with children, but is predicted to have no effect on another group, single women without children. Other features of TRA86, such as the increase in the value of dependent exemptions and the large increase in the standard deduction for head of household filers, are predicted by economic theory to have reinforced the impact of the

3. We assume that the full incidence of payroll taxes falls on the worker. The net marginal tax rate is the share of the worker's marginal revenue product that is paid in taxes and lost benefits. A worker whose gross pay is \$10 an hour would have a marginal revenue product of \$10.765, since the employer pays half of the OASDHI payroll tax. After subtracting \$1.50 for federal income tax, \$.60 for state income tax, \$.765 for the employee's share of OASDHI, and \$2.106 in lost EITC payments, the taxpayer has a net of tax and benefits hourly wage of \$5.029. Dividing the total tax and lost benefits \$5.736 by \$10.765 yields a marginal tax rate of 53.3 percent. If some of employee compensation is in untaxed benefits, then this is an overstatement of marginal tax rates.

EITC on the *relative* labor supply outcomes of single women with and without children. We therefore compare the change in labor supply of single women with children to the change in labor supply of single women without children. We find that after TRA86, the labor force participation of single women with children increased by up to 2.8 percentage points relative to single women without children (from a base of 73.0 percent). We explore a number of alternative explanations for this finding, and conclude that the expansion of the EITC and the other provisions of TRA86 are the most likely explanation. We find no effect of the EITC expansion on the hours of work of single women with children who were already in the labor force.<sup>4</sup>

The remainder of the paper is divided into six sections. Section I explains the eligibility rules and structure of the EITC and outlines the predicted impact of the EITC on participation and hours of work. Section II discusses our identification strategy and our various treatment and control groups. Section III describes the data. Section IV presents empirical results for labor force participation. Section V presents estimates for hours and total employment. Section VI concludes.

### I. THE STRUCTURE OF THE EITC

The earned income tax credit began in 1975 as a modest program aimed at offsetting the social security payroll tax for low-income families with children. After major expansions in the tax acts of 1986, 1990, and 1993, the EITC has become a central part of the federal government's antipoverty strategy. By 1996 federal spending on the EITC (including both tax expenditures and outlays) is projected to be 1.7 times as large as federal spending on AFDC.

A taxpayer currently needs to meet three requirements in order to be eligible for the earned income tax credit. First, the

4. A number of other papers have analyzed labor supply response to the EITC. We believe, however, that our paper is the first that estimates actual behavioral responses to a change in the credit. Three papers have used estimates from the negative income tax experiments to predict the impact of the EITC on labor supply [Hoffman and Seidman 1990; GAO 1993; Holtzblatt, McCubbin, and Gillette 1994]. In addition, Dickert, Houser, and Scholz [1995] estimate a joint labor market and welfare participation model that incorporates the EITC. Using their results and hours of work elasticities from the labor supply literature, they simulate the effects on labor supply of the recent expansion of the EITC. Finally, Triest [1993] and Browning [1995] present opposing views on whether the EITC is an efficient method of transferring income to low-income families.

taxpayer must have positive earned income. Earned income is the sum of wage and salary income, business self-employment income, and farm self-employment income. Second, a taxpayer's adjusted gross income and earned income must both be below a specified amount (In 1996 the maximum income for a taxpayer with two or more children to be eligible to receive the EITC is \$28,495). Third, a taxpayer must have a qualifying child.<sup>5</sup> A qualifying child is a child, grandchild, stepchild, or foster child of the taxpayer who is under the age of 19 (under 24 if a full-time student) or permanently disabled, and who lives with the taxpayer for more than one-half of the tax year. Until 1991 the rules for EITC eligibility were more complicated and depended on the taxpayer's filing status.<sup>6</sup> The credit is refundable so that a taxpayer with no federal tax liability, for example, would receive a tax refund from the government for the full amount of the credit. Taxpayers may also receive the credit throughout the year with their paychecks; but in 1992, the most recent year for which data are available, less than one-half of 1 percent of all EITC recipients availed themselves of this early payment option [Internal Revenue Service 1992].

The amount of the credit to which a taxpayer is entitled depends on the taxpayer's earned income, adjusted gross income, and, since 1991, the number of EITC-eligible children in the household. In 1996 the credit for a family with two or more children is phased in at a 40 percent rate over the first \$8890 of earned income, resulting in a maximum credit of \$3556. As income rises from \$8890 to \$11,610, the credit remains at \$3556. Then the credit is phased out at a 21.06 percent rate on income starting from \$11,610 (the maximum of AGI and earned income governs the phaseout), so that by \$28,495 the taxpayer is no longer eligible for the credit.

Figure I shows how the introduction of an EITC shifts the

5. Beginning in 1994, a small credit is available to low-income workers without children.

6. Before 1991 a taxpayer could claim the EITC only if he or she used a filing status of married filing jointly, head of household, or surviving spouse. A married taxpayer could claim the EITC only if he or she claimed a dependent child on his or her tax return, and the child lived with the taxpayer for more than six months during the year. An unmarried taxpayer filing as head of household did not have to claim the child as a dependent in order to be eligible for the EITC, but, in order to file as head of household, the taxpayer must have paid more than half the cost of keeping up the home. Therefore, both married filers (through the rules for claiming a dependent) and head of household filers were required to meet a support test. AFDC payments are not considered support provided by the taxpayer. Consequently, a taxpayer with \$6000 in AFDC income and \$5000 in earned income was not eligible for the EITC under pre-1991 rules.

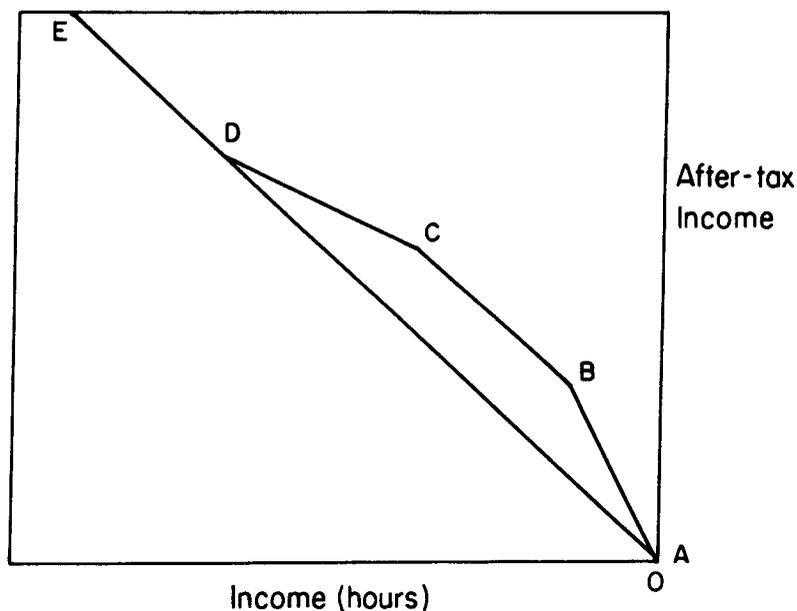

FIGURE I  
EITC Budget Constraint

budget constraint of an otherwise untaxed individual from *ADE* to *ABCDE*. Under the new budget constraint every choice of hours (or equivalently pretax earnings) produces at least as much after-tax earnings (and utility) as it did before the earned income tax credit was introduced. The well-being of a taxpayer who does not work has not changed because no earned income tax credit is available to a taxpayer with zero earnings. Thus, any taxpayer who preferred working before will still prefer working, and some taxpayers may find that the additional after-tax income from the EITC makes it worth entering the labor force. The impact of the EITC on the labor force participation of unmarried taxpayers is therefore unambiguously positive.

The impact of introducing an EITC on the hours of work of a taxpayer already participating depends on which region of the EITC the taxpayer was in before the credit was introduced. For a worker in the phase-in, the effect on labor supply is theoretically ambiguous: the credit subsidizes the worker's wage so that the substitution effect encourages additional hours while the income effect causes hours to decrease. For a worker in the constant region, there is only an income effect, reducing hours. In the phase-

out region the EITC unambiguously reduces labor supply since there is both a negative substitution effect from the credit being phased out and a negative income effect from the additional income the credit provides to the taxpayer. Beyond the credit region, taxpayers may decide to reduce their hours of work and receive the credit.

## II. IDENTIFICATION STRATEGY

We study the labor supply response of single women with children to the 1987 expansion of the earned income tax credit, which occurred as part of the Tax Reform Act of 1986. We focus on single women with children because they are the largest group of taxpayers eligible for the EITC, making up approximately 48 percent of the EITC eligible population in the March 1992 CPS [Eissa and Liebman 1993]. In addition, they are the group most relevant for studying whether the EITC reduces welfare dependency. Finally, they are the group for which we can most plausibly ignore the joint labor supply decisions of other family members, and thus derive simple predictions from labor supply theory.<sup>7</sup> We study the 1987 expansion of the credit because it was the largest EITC expansion that was not phased in over a number of years. The incentives created by the 1987 expansion of the EITC were reinforced by other tax changes implemented after the Tax Reform Act of 1986, making the relative impact on single women with children similar in size to the larger EITC expansions of the 1990s.

The 1987 expansion of the EITC increased the subsidy rate for the phase-in of the credit from 11 percent to 14 percent and increased the maximum income to which the subsidy rate was applied from \$5000 to \$6080. This resulted in an increase in the maximum credit from \$550 to \$851 (\$788 in 1986 dollars). The phaseout rate was reduced from 12.22 percent to 10 percent.

7. In a two-parent family the credit may reduce the probability of participation for the secondary earner through an income effect. The overall effect on family labor supply will depend critically on the model of labor supply assumed to hold at the household level and on the distribution of earnings within the family. In 47 percent of married couples earning less than \$25,000, the woman accounts for at least 40 percent of the family's earnings (March 1993 CPS). Therefore, the common assumption that a family's marginal tax rate is determined by the male's earnings may not be appropriate for this population. Even for household heads, the simple model may not be sufficient. Edin and Jencks [1993] show that most single mothers receiving AFDC also receive income from boyfriends and extended family members, and often have unreported labor income.

The higher maximum credit and the lower phaseout rate combined to expand the phaseout region. Taxpayers with incomes between \$11,000 and \$15,432 became eligible for the credit and faced its phaseout marginal tax rate for the first time in 1987. The constant region was lengthened in 1988, further extending the phaseout region to \$18,576. At every level of earnings the EITC amount after the expansion was at least as large as it was before. Therefore, theory predicts that labor force participation of eligible taxpayers will increase in response to the expansion.

The positive impact of the EITC expansion on the average return to work was reinforced by other elements of the Tax Reform Act of 1986. TRA86 increased the standard deduction for a taxpayer filing as head of household from \$2480 in 1986 to \$4400 in 1988 (the standard deduction for single taxpayers rose from \$2480 to \$3000). TRA86 further reduced the tax liability of taxpayers with children by increasing the deduction per dependent exemption from \$1086 in 1986 to \$1950 in 1988. Finally, the tax schedules were changed. The tax schedule changes were particularly beneficial to head of household filers because the increased standard deduction and exemption amounts meant that in 1988 the typical head of household filer did not jump from the 15 percent tax bracket to the 28 percent tax bracket until her AGI exceeded \$33,565. In contrast, a single filer would begin paying 28 percent on AGI over \$22,800.

In contrast to the positive predicted impact of the EITC expansion on the labor force participation of single workers with children, the expansion should have decreased hours of work for most eligible taxpayers who were already in the workforce. A more detailed discussion of the impact of the 1987 expansion on hours of work is deferred until Section V.

Our estimation strategy compares the labor force participation and hours worked of single women with children before and after TRA86. Most single women with children are eligible for the EITC (if they have appropriate incomes), and if they file tax returns, they usually file as household heads. While the difference between the 1988 and 1986 tax liability of a taxpayer varies by income, we cannot use this variation as the basis of our work because the amount of tax paid by a taxpayer and her labor supply are endogenously determined. Thus, the "treatment" in this natural experiment is not a specific change in tax liability. Rather, it is the entire shift in the budget constraint. In practice, therefore, we rely on time to identify the responsiveness of female

household heads to the EITC and the other aspects of TRA86. Since there may be underlying trends in participation or hours of work and there may be other policy or economic shocks that affect labor market outcomes, we use control groups to allow us to isolate the impact of TRA86 from other factors. A good control group is similar in its characteristics to the treatment group—and therefore likely to respond similarly to the underlying trends or contemporaneous shocks—but does not receive the treatment.

As we explained earlier, eligibility for the EITC depends on the presence of a child in the tax unit and on income being above zero and below the level at which the credit is completely phased out. The expansion of the EITC may, however, affect taxpayers with incomes beyond the level at which the credit is completely phased out since they might reduce their hours (and incomes) and take advantage of the increased credit. Therefore, we use all single women with children as our primary treatment group.<sup>8</sup> We use all single women without children as the control group. The difference between the change in labor force participation of single women with children and the change of single women without children is our estimate of the effect of TRA86 on participation. This is essentially the difference-in-differences approach. It controls for any contemporaneous shocks to the labor force participation of single women with children through the change in participation for the control group. The two identifying assumptions that we make are (1) there are no contemporaneous shocks (other than the tax changes) to the relative labor market outcomes of the treatment and the control groups over the period of the reforms; and (2) there are no underlying trends in participation or hours of work that differ between the two groups.<sup>9</sup>

By including all single women with children in the treatment

8. We are assuming that the taxpayer's marital status and the presence of children in the tax filing unit are exogenously determined. To test whether our results are sensitive to the assumption that fertility decisions are exogenous, we reestimated our basic model using as our treatment group only women who had a qualifying child over age five. Our results did not change.

9. Contamination of the treatment and control groups (which would bias our results toward zero) should not be a large problem in this application. We have checked our allocation methodology using a CPS-IRS match described in Liebman [1995]. We find that 89 percent of women whom we allocate to the treatment group and who file a tax return claim a dependent child on that tax return (80 percent of treatment group filers, file as head of household). Ninety-five percent of women whom we allocate to the control group and who file a tax return, do not claim a dependent child on that tax return (91 percent file as single). If misallocation of individuals to the treatment group and control group happens at random, then these results imply that we should increase our labor-supply results by 19 percent.

group, we are including many taxpayers (those with high incomes) who are unlikely to be affected by the EITC. It also increases the importance of the non-EITC aspects of TRA86, since those effects were larger at incomes beyond the phaseout of the EITC. In addition, the broad treatment group makes it difficult to find good control groups. To focus on the impact of the credit on low-income families, we use two alternative treatment groups. The first is single women with children and low levels of education,<sup>10</sup> and the second is single women with children whom we predict (using exogenous characteristics such as age, race, state, and education) would have earned incomes making them eligible for the EITC. For each of these treatment groups, we use two control groups: single women without children and with low levels of education (predicted income in the EITC range), and single women with children and more than high school education (predicted income above the EITC maximum income). The second control group is more similar to the treatment group on one dimension—they have children—but less similar on another: they have higher education levels (predicted income beyond the EITC range).

The advantage of having multiple control groups is that if we find similar results, we can be more confident that we are estimating the actual effect of the tax reforms and not just the effect of other contemporaneous changes or trend differences between the control and treatment groups. Ultimately, then, the credibility of our results lies in the consistency of our estimates across different treatment and control groups rather than on any one estimate.

### III. DATA

The data we use are from the 1985 to 1987 and 1989 to 1991 March Current Population Surveys. The March CPS is an annual demographic file of approximately 57,000 households. It includes labor market and income information for the previous year, so the data we have are for tax years 1984 to 1986 and 1988 to 1990. We exclude 1987, the first year after TRA86, to allow taxpayers time to adjust their behavior.

The CPS contains information on households, families, and

10. We use two definitions of low education: less than twelve years of education and exactly twelve years of education.

individuals. However, the relevant unit of analysis for this study is the tax-filing unit. Our tax-filing units are based upon CPS families. Therefore, subfamilies (both related and unrelated) are allocated to separate tax-filing units from the primary family. We consider any member of the tax-filing unit who is under the age of 19 (or under 24 and a full-time student) to be a dependent child for tax purposes. We do not impose the support test for dependents because the test includes factors, such as AFDC income, that are endogenous to labor supply decisions. In addition, we do not have enough information to impose the EITC six-month residency test. Therefore, we assume that any taxpayer with a child under the age of 19 (or under 24 and a full-time student) meets both the dependent child and EITC child requirements.

The sample includes unmarried females (widowed, divorced, and never married) who are between 16 and 44 years old. We exclude any female who is separated from her spouse during the reference period, or who was ill or disabled, or in school full time during the previous year. We also exclude any woman with negative earned income (due to negative self-employment income), negative unearned income, or with positive earned income but zero hours of work. The resulting sample size, after pooling all six years, is 67,097 observations.

Table I presents summary statistics of the characteristics of the treatment and control groups. Column 1 presents the characteristics of all unmarried females without children (control); column 2 presents characteristics of all unmarried females with children (treatment). There are some noticeable differences between the two groups. Those who have children tend on average to be older (31.17 versus 26.78 years), less educated (12.05 versus 13.44 years of education), and less likely to have been in the workforce at any time during the previous year (.74 versus .95 probability of annual hours greater than zero). Average earnings for women with children are less than earnings for those without children. Conditional on working, however, the two groups have similar mean earnings. In columns 3, 4, and 5, we present characteristics for women with children who have completed less than twelve years of schooling, twelve years, and more than twelve years, respectively. Again there appear to be systematic differences between the attributes of the groups. The more educated the female head is, the more likely she is to be older, to have a smaller family, and to be a member of the labor force.

These summary statistics suggest that any raw differences

TABLE I  
SUMMARY STATISTICS

Variable	Group

Observations	46,287	20,810	5396	9702	5712

Data are from survey years 1985–1987 and 1989–1991 of the March Current Population Survey (CPS). The sample contains *unmarried* women between the ages of 16 and 44. We exclude women who were separated during the previous year, ill or disabled, in school. We also exclude women with negative earnings, negative unearned income, or with nonzero earnings and zero hours of work. All figures are in 1992 dollars. Preschool children is the share of the sample with preschool children. Labor force participation equals one if annual hours are positive, zero otherwise. Weekly participation equals annual weeks worked divided by 52. Standard deviations are in parentheses. Means are weighted with CPS March supplement weights.

in labor market outcomes over time between the treatment and control groups must be interpreted with caution, since the differences could reflect nontax shocks that affect people with some characteristics differently from people with other characteristics. The methods used to control for demographic differences will be critical to our analysis. These results also confirm our earlier point that there is no ideal control group. Only if results are consistent across different specifications will we have strong evidence of a tax effect.

#### IV. EMPIRICAL RESULTS FOR LABOR FORCE PARTICIPATION

##### *A. Basic Participation Results*

Table II presents labor force participation rates for the treatment groups and control groups in the years before and after the Tax Reform Act of 1986. We define labor force participation as working a positive number of hours during the year. We use this definition of labor force participation because it is the one for which the predicted impact of the EITC is unambiguous. In each panel the first column corresponds to the average participation rate prior to TRA86; the second column to the average after TRA86; and the third column to the change in participation. The difference-in-differences estimate of the participation response is in the last column. Panel A presents the results for the first treatment group (all unmarried females with children) and control group (all unmarried females without children). The participation rate of the treatment group increased by a statistically significant 2.4 percentage points (from 72.9 percent to 75.3 percent). There was no change in labor force participation for unmarried women without children. The fact that the participation rate of the control group did not change is important, because it suggests that there is not much of an aggregate effect of which to take account. We would be concerned if there were substantial changes in the participation rate for the control group, because, in that case, our difference-in-differences estimator would depend heavily on the quality of the control group. Our first estimate of the participation response then is 2.4 percentage points, with a standard error of 0.6.

To further examine whether it was the EITC that caused the participation rate of female household heads to rise, we next focus on the subset of females with children who were most likely

TABLE II  
LABOR FORCE PARTICIPATION RATES OF UNMARRIED WOMEN

	Pre-TRA86 (1)	Post-TRA86 (2)	Difference (3)	Difference-in- differences (4)

<i>Control group:</i>				
Without children [46,287]	0.952 (0.001)	0.952 (0.001)	0.000 (0.002)	0.024 (0.006)
<i>B. Treatment group:</i>				
Less than high school, with children [5396]	0.479 (0.010)	0.497 (0.010)	0.018 (0.014)	
<i>Control group 1:</i>				
Less than high school, without children [3958]	0.784 (0.010)	0.761 (0.009)	-0.023 (0.013)	0.041 (0.019)
<i>Control group 2:</i>				
Beyond high school, with children [5712]	0.911 (0.005)	0.920 (0.005)	0.009 (0.007)	0.009 (0.015)
<i>C. Treatment group:</i>				
High school, with children [9702]	0.764 (0.006)	0.787 (0.006)	0.023 (0.008)	
<i>Control group 1:</i>				
High school, without children [16,527]	0.945 (0.002)	0.943 (0.003)	-0.002 (0.004)	0.025 (0.009)
<i>Control group 2:</i>				
Beyond high school, with children [5712]	0.911 (0.005)	0.920 (0.005)	0.009 (0.007)	0.014 (0.011)

Data are from the March CPS, 1985-1987 and 1989-1991. Pre-TRA86 years are 1984-1986. Post-TRA86 years are 1988-1990. Labor force participation equals one if annual hours are positive, zero otherwise. Standard errors are in parentheses. Sample sizes are in square brackets. Means are weighted with CPS March supplement weights.

to be affected by an increase in the EITC: those with low education levels. Panel B presents participation rates for women with children and less than high school education, compared with women with the same level of education and no children, and also compared with more educated women with children. Panel C repeats the exercise for individuals with exactly twelve years of education. The participation rate before TRA86 was 47.9 percent for women with children and less than a high school education, compared with 78.4 percent for women without children and less than a high school education, and 91.1 percent for women with children and more than a high school education. After TRA86 there is an increase in the participation rate of 1.8 percentage points (from 47.9 percent to 49.7 percent) for the “less than high school” treatment group. There is a 2.3 percentage point *drop* in the participation rate of the first control group (females with less than high school education and no children). Taken together, these figures suggest a participation response of 4.1 percentage points. The second control group, females with children and more than high school education, has a small increase in participation of 0.9 percentage points, producing a difference-in-differences estimate that is also 0.9. Since many single women with children and more than high school education are eligible for the EITC and therefore are likely to be affected by its increase, it is not surprising that the second control group produces a smaller estimate of the treatment effect than the first control group. For the “high school” treatment group, shown in Panel C of Table II, the corresponding range of estimates is 1.4 to 2.5 percentage points.<sup>11</sup>

These results suggest that the labor force participation of unmarried heads of households increased following the Tax Reform Act of 1986. We do not observe a similar increase in the control groups. We observe larger percentage point responses among female heads with twelve or fewer years of schooling than among women with more education. This is encouraging since they are the most likely to be affected by the EITC.<sup>12</sup>

11. Because the level of participation for the treatment group differs from the level for the control group, the tax effect could be sensitive to the way in which we define the participation change. For example, we could find a greater percentage point increase in participation for the treatment group than for the control group, while finding a smaller percent reduction in nonparticipation. Because all of the without children control groups have either zero or negative changes in participation, our main qualitative results are not sensitive to the specification of the participation effect. However, our results comparing women with children and different levels of education are sensitive to the measure chosen.

12. Since the participation rate of the control group is so high (95 percent), a potential concern is that there is not much scope for the rate to rise after TRA86.

### B. Regression Results

Because the treatment and the control groups differ in demographic characteristics, the observed differences in participation outcomes may reflect underlying differences between the treatment and control groups rather than a treatment effect. Controlling for demographic characteristics in a difference-in-differences approach is important if the composition of the treatment or control groups changes over time and some demographic characteristics are correlated with the dependent variable. In addition, controlling for demographic characteristics reduces the residual variance of the regression and produces more efficient estimates. Finally, by interacting demographic characteristics with a time dummy, we are able to reduce the chance that unknown shocks that differentially affect people with different characteristics are producing a false treatment effect.

We estimate the probit equation:

$$(1) \quad P(lfp_{it} = 1) = \Phi(\alpha + \beta \mathbf{Z}_{it} + \gamma_0 treatment_i + \gamma_1 post86_i + \gamma_2 (treatment \times post86)_{it}),$$

where  $lfp$  is a dummy equal to one if a woman reported working at least one hour during the previous year. In our basic specification,  $\mathbf{Z}_{it}$  is a vector that includes unearned income, number of children, family size, number of preschool children, age and its square and cube, education and its square, and a dummy variable for race (=1 if nonwhite).  $\mathbf{Z}_{it}$  also includes year dummies for 1984, 1985, 1989, and 1990. These variables control for observable differences in the characteristics of the treatment and control group that affect the level of labor force participation. Unobservable differences are controlled for by the variable,  $treatment$ , which is equal to one for any woman who has a child in her subfamily (and is therefore eligible for the EITC and likely to file as a household head). We expect  $\gamma_0$  to be negative if women with children have

---

The evidence using the less than high school control group (with a participation rate of 78 percent) provides some reassurance on this point. In addition, we examined two other potential control groups: low-educated married women without children and low-educated single men without children. The labor force participation of the married women increased by 0.2 percent, from 83.9 to 84.1 percent, after TRA86, providing further evidence that the 2.3 percent increase observed for single women with children is larger than that observed for other groups in the economy. The labor force participation of single men rose from 93.5 percent of 94.5 percent. We take this as evidence that our methodology would have been capable of observing an increase in labor force participation by single women without children if one had occurred, even though they started from a high level of participation.

lower participation rates than their counterparts without children, even after controlling for other observable demographic characteristics. *post86* is a dummy equal to one for any tax year after 1986.  $\gamma_1$  therefore reflects the average change in labor force participation for both treatment and control groups between 1986 and 1988, the omitted year-dummies in the regression.

A test of the impact of TRA86 is a test that eligible, unmarried women with children increased their participation after 1987 relative to unmarried women in the control group. It is a test that  $\gamma_2$ , the coefficient on the interaction term between *post86* and *treatment*, is greater than zero. Thus, our hypothesis tests are one-tailed tests (the ninety-fifth percentile of the *t*-distribution is 1.64).

Table III presents results in which we use the presence of children as our measure of eligibility for the EITC and the head of household filing status (*kids* replaces *treatment* in equation (1)). The sample is all unmarried women. The first column excludes demographic characteristics, while the second column includes them. The estimated coefficients on the four year dummies (not reported) and *post86* ( $\gamma_1$ ) are small in magnitude and insignificant in both columns, suggesting that there is no overall trend in average participation for the two groups. The coefficient on *kids* ( $\gamma_0$ ) changes dramatically once demographic characteristics are included: from  $-1.053$  to  $-0.250$ . This result should not be surprising since females with children have different attributes than women without children. The fact that  $\gamma_0$  remains significant even after controlling for observable characteristics suggests that having a child reduces labor force participation even controlling for observable demographic variables or that there are unobservable differences across the two groups. In spite of these differences, however, the treatment effect ( $\gamma_2$ ) changes little when we include demographic characteristics as regressors: it rises from 0.069 to 0.074 (with a standard error of .030). This result suggests that any changes in the demographic composition of the treatment and control groups that occurred over time are uncorrelated with the treatment. The coefficients on the other demographic characteristics all have the expected signs. Females with unearned income have lower probabilities of participation, as do females with preschool children. Older women have lower probabilities of participation, as a cohort effect would predict. Finally, educated women are more likely to be in the labor force than less

educated women (the quadratic term dominates the linear term for years of schooling of two or more).

The probit is a nonlinear model; therefore, the coefficients cannot be used directly as marginal effects. Since the treatment effect variable ( $kids \times post86$  interaction) is discrete, we calculate the effect of the TRA86 by predicting two probabilities of participation, one with the interaction variable set equal to one and the other with the interaction term set equal to zero. The treatment effect is the average (over the sample of post-1987 women with children) of the difference in the two probabilities of participation. The last row in Table III presents estimates of the treatment effect. In column (2) we find that female heads had a 1.9 percentage point higher probability of participating in the workforce as a result of the combined impact of the expansion of the earned income tax credit and the other TRA86 reductions in tax liability for single women with children. The standard error on this estimate is 0.8 percentage points.<sup>13</sup>

### C. Alternative Explanations

The basic finding from both the participation means and the regressions that the relative labor force participation of single women with children increased in the years after 1987 is consistent with TRA86 having a positive impact on labor force participation. However, there are a number of alternative explanations for this finding that need to be examined before we conclude that TRA86 is the most likely explanation for the increase in labor force participation.

Labor force participation rates for all women increased from 37.1 percent in 1959 to 57.4 percent in 1989. If long-run trends in labor force participation differ between females with and without children, then we risk interpreting preexisting differences in labor supply patterns as treatment effects. The top panel of Figure II shows the labor force participation rate for all unmarried females, aged 16 to 44, between 1981 and 1992. We present separate trends for women with and without children. The labor force participation rate for women without children does not appear to be trending either upward or downward during this period. The participation rate for women with children seems to be somewhat more sensitive to the business cycle. There also appears to be an

13. We use the delta method to calculate the standard errors.

Data are from survey years 1985-1987 and 1988-1991 of the March CPS. The dependent variable is labor force participation. It equals one if the woman worked at least one hour during the tax year. *Post86* equals one for tax years 1988, 1989, 1990. *Kids* equals one if the tax filing unit contained at least one child. In addition to the variables shown, all regressions include year dummies for 1984, 1985, 1989, and 1990. Columns (2) through (6) also include variables for the number of children in the tax filing unit age-cubed. Columns (3) through (6) also include interactions of *age* and *nonwhite* with *post86* and with *kids*. Columns (4) through (6) also include a full set of state dummies. Column (5) also includes interactions of *second child* with the year dummies for 1988, 1989, and 1990. The number of observations is 67,097. Standard errors are in parentheses. Regressions are weighted with CPS March supplement weights.

## All Unmarried Females

## Unmarried Males With Less Than High School Education

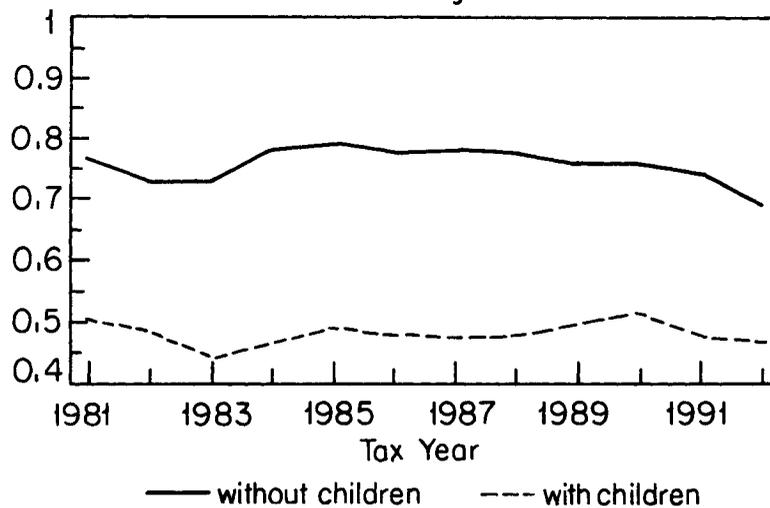

FIGURE II  
Labor Force Participation Rates 1981 to 1992, Unmarried Females Ages 16-44

increase in labor force participation after 1986 for women with children, while the rate for women without children trends upward only slightly. The bottom panel of Figure II shows the same trends for women with less than high school education. Once again, there is no evidence that the two groups have different long-run trends.

In order to rigorously check these visual impressions, we estimated a probit regression of labor force participation on thirteen year dummies, a dummy for children, and interactions of the children and year dummies. To control for changes over time in the demographic composition of the sample, we also included all the demographic variables from column (2) of Table III. The marginal effects of the interaction variables represent annual deviations from the average difference in participation between females with children and females without children. These marginal effects and the maximum EITC are plotted in the top panel of Figure III for all women and in the bottom panel of Figure III for women with less than high school education. The two figures show quite clearly that the difference in participation rates between females with children and females without children declines (the coefficients become less negative) following the 1987 increase in the maximum credit. The participation rate difference seems to track the maximum EITC quite closely with a one- or two-year lag. It seems safe to conclude that the response estimated for the 1987 expansion does not reflect differing trends in the labor force participation of females with children and females without children. Indeed, the long-run evidence seems to confirm the conclusion that the relative labor force participation of women with children increased after 1986.

Another possible explanation for our finding that the relative labor force participation of single women with children increased after 1987 is that some other change occurred in the economic environment which affected women with children differently than women without children. Likely candidates are changes in state AFDC benefits, business cycle fluctuations, or unknown shocks that affect people with different demographic characteristics differently. While there was little change in national average AFDC benefits over our period of analysis, there was some cross-state variation in real benefits. For example, between 1986 and 1988, the maximum monthly benefit for a woman with two children increased from \$430 to \$503 (1992 dollars) in New Hampshire, and from \$505 to \$577 in Massachusetts. In New York, on

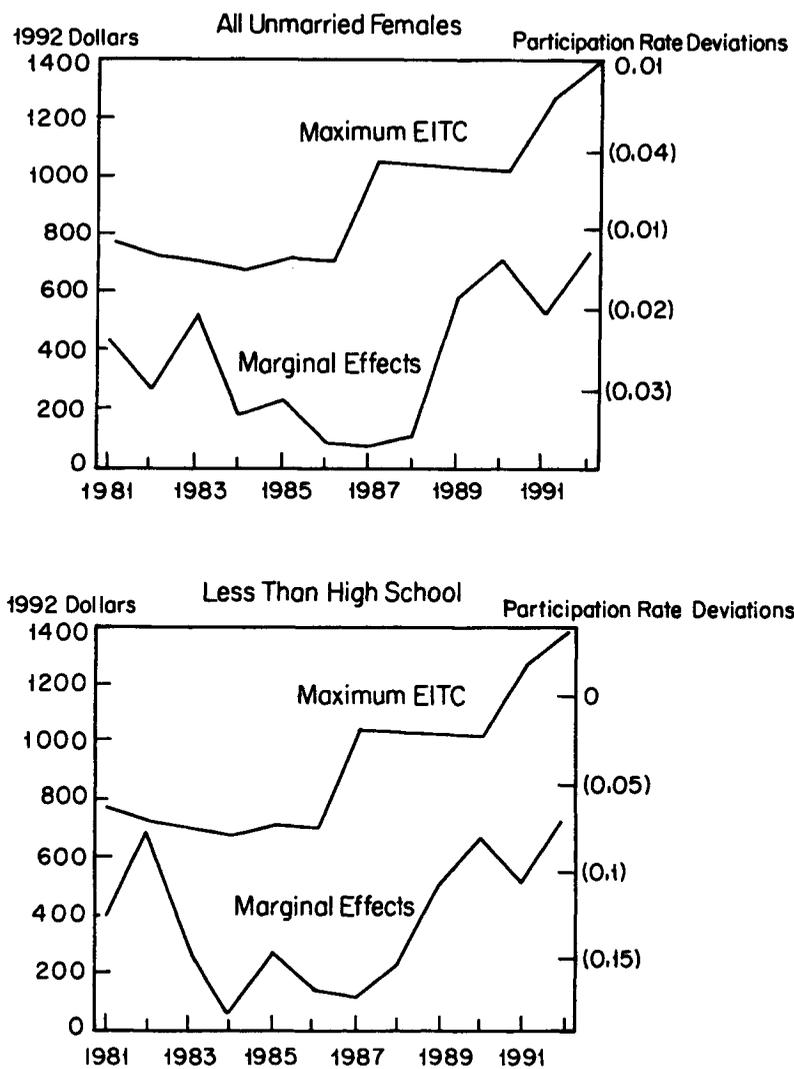

FIGURE III  
Maximum EITC and Marginal Effects from  $KID \times YEAR$  Dummies

the other hand, the maximum benefit fell from \$533 to \$495, and in California it fell from \$638 to \$606. The business cycle could be driving our results if there is a difference between single women with and without children in the sensitivity of their labor

force participation to macroeconomic shocks. Between 1986 and 1988 the national unemployment rate for females fell by 1.8 percentage points, from 7.1 to 5.3 percent. Since both a reduction in the unemployment rate and an increase in the EITC should increase labor force participation, it is not possible to isolate the effects of the credit from the effects of the business cycle using the national unemployment rate. However, research has shown that the employment and earnings status of less educated, younger workers is closely related to state and local labor market conditions [Bartik 1991; Freeman 1991]. Therefore, we use state unemployment rates to purge the effects of general business cycle movements from our treatment effects. Finally, it is possible that the measured EITC response is the result of unknown shocks that are correlated with demographic characteristics that differ between the treatment group and the control groups. For example, nonwhite women may have been induced to enter the labor force during this period for reasons other than TRA86. We have no good story for why this might have happened, perhaps a shock to tastes for work, or perhaps changes in incentives that we have not captured. In any case, since unmarried women with children are more than twice as likely to be nonwhite than are unmarried women without children (37 percent versus 15 percent), such shocks could explain our results. To address these concerns, we include interaction terms between the time dummy and age and race.

Columns (3) and (4) of Table III display results including state AFDC benefits, state unemployment rates, and the interactions between demographic characteristics and time. The unemployment rate is negatively correlated with labor force participation as is the level of monthly AFDC benefits. Surprisingly, the interaction between the unemployment rate and *kids* is positive, suggesting that women with children are less sensitive to the business cycle. The treatment effect,  $kids \times post86$ , rises after controlling for the alternative explanations. The predicted participation response increases from 1.9 percentage points in column (2) to 2.6 percentage points in column (3). When state dummies are added in column (4), the estimated response increases further to 2.8 percentage points. Thus, it does not appear that the alternative explanations we have considered here can account for the relative increase in participation that we observe following TRA86.

#### D. Was the EITC the Cause?

Three other pieces of evidence increase the likelihood that the observed effect was due to the EITC and not to other parts of TRA86 or other government policies. First, the increase in participation is mostly a response to the return to the first child in the tax unit. In the period we study, the amount of EITC a taxpayer received depended only on having a child. No additional benefit accrued from having only one child. Similarly, the advantages of the head of household filing status come from the initial child. In contrast, additional dependent exemptions are available for each additional child. Thus, if families with multiple children were more likely to increase their labor force participation than families with more than one child, then this part of the response was due to the expansion of the dependent exemption and not to the EITC. To disentangle the EITC and head of household effect from the dependent exemption effect, we estimate a regression in which we interact a *second child* dummy with the *post86* dummy. Column (5) of Table III shows that after including the second-child effect, there is still a 2.2 percentage point effect attributable to the first child.

Second, the timing of the post-1987 participation increase is consistent with the result being due to the increase in the EITC. The top panel of Figure III indicates that there was little relative increase in participation by women with children until 1989. The bottom panel indicates that for women with less than high school education, there was some increase in 1988, but most of the increase occurred in 1989. Column (6) of Table III estimates the magnitude of the individual year effects. By 1988 single women with children had increased their relative labor supply by only 0.8 percentage points, but in 1989 and 1990 the impact reached 2.9 percentage points. This timing is consistent with the response being due to the increase in the EITC. Most EITC recipients would have first become aware of the increase around April of 1988 when they received their 1987 tax refund. Assuming that it takes some time to adjust to new incentives, we would expect to have seen a limited response in 1988, and a full response in 1989. Other aspects of TRA86 appeared in weekly paychecks during 1987 and would be expected to have provoked a more rapid response. The finding that most of the increase in relative participation rates occurred in 1989 is evidence that the increase was not caused by the Family Support Act of 1988. States were not

required to implement many of the key provisions of the Family Support Act until mid-1990 [Committee on Ways and Means 1994], so we would have expected it to have had a larger impact in 1990 than in 1989.<sup>14</sup>

The third piece of evidence that the effect we observe is due to the EITC is that it had its largest effect among people most likely to be eligible for the credit. Columns (1) through (3) of Table IV present results with the sample separated by years of education. The specification is the same as column (5) of Table III. The predicted participation response is 6.1 percentage points for the less than high school sample, 2.6 percentage points for the high school sample, and only 0.4 percentage points for the beyond high school sample.<sup>15</sup> When we separate the sample by predicted income region, we obtain similar results.<sup>16</sup> The 86 percent of the sample whom we predict to have earnings in the EITC range have a predicted participation response of 3.6 percentage points, while the predicted high-income individuals have a participation response of  $-0.7$  percentage points.

## V. THE IMPACT OF THE EITC ON HOURS WORKED

### A. Basic Hours Results

The results presented in the previous section show that the relative labor force participation of single women with children increased following TRA86 and suggest that the EITC could have been the cause of this participation increase. However, the EITC expansion is predicted to have reduced the hours worked by many single women with children already in the labor force. Thus, the total impact of the EITC on hours worked is theoretically ambiguous.

14. Some states expanded Medicaid access for families with small children during the years studied in this paper [Yelowitz 1995]. As we explained in footnote 8, restricting our sample to families with children over five years of age does not change our results, so these Medicaid expansions cannot be the source of our findings.

15. A difference-in-differences regression of less than high school versus more than high school, women with children versus women without children, and pre-1986 versus post-1986 (using the same covariates as in Table IV) generates a predicted participation response of 10.6 percentage points.

16. Since the low education groups do not correspond exactly to the EITC eligible population, we estimate an earnings equation using the sample of earners prior to 1987. We estimated an OLS regression of earnings on family size, number of preschool children, the state unemployment rate, and 28 age dummies, 10 education dummies, 2 year dummies, and 1 race dummy. Using the estimated coefficients and individual characteristics, we predict earned income for each woman in the sample.

Data are from survey years 1985-1987 and 1989-1991 of the March CPS. The dependent variable is labor force participation. It equals one if the woman worked at least one hour during the tax year. *Post86* equals one for tax years 1988, 1989, and 1990. *Kids* equals one if the tax filing unit contained at least one child. In addition to the variables shown, all regressions include all the variables from the specification in column (5) of Table III. Standard errors are in parentheses. Regressions are weighted with CPS March supplement weights.

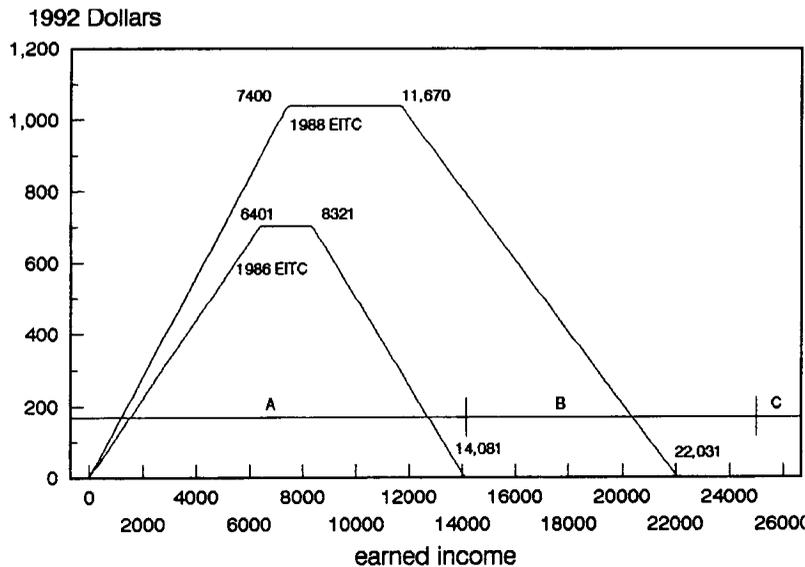

FIGURE IV  
1986 and 1988 Earned Income Tax Credit

Figure IV displays the 1986 and 1988 earned income tax credits (in 1992 dollars) as functions of income. The predicted impact of the EITC expansion on hours of work depends on the taxpayer's income. For most workers in region A (incomes between \$0 and \$14,081), the EITC expansion is predicted to have an ambiguous impact on hours of work since the expansion had offsetting income and substitution effects. Workers in region B (incomes between \$14,081 and \$25,000) are predicted to reduce their hours of work because they are either in the expanded phaseout region and face a 10 percent higher marginal tax rate in addition to having their incomes increased or because they have incomes just beyond the expanded phase-in region and might reduce their hours of work to take advantage of the credit. Workers in region C (incomes above \$25,000) are unlikely to be affected by the increase in the credit.<sup>17</sup>

17. The TRA86 tax rate changes reinforced the effect of the EITC on the hours of work of household heads relative to single filers. TRA86 reduced marginal tax rates by between three and eight percentage points for most single taxpayers with incomes in the EITC phaseout range, while reducing marginal tax rates for household heads by only two to three percentage points. Thus, the substitution effect from TRA86 should cause a larger increase in hours from single taxpayers than from household heads. In addition, as we explained in the participation section, the new TRA86 brackets, through their interaction with the in-

To examine how the EITC expansion affected hours conditional on working and total hours, we estimate OLS regressions that are similar to the probits that we used in Section IV. Thus, we estimate

$$(2) \quad \text{Annual Hours}_{it} \\ = \alpha + \beta \mathbf{Z}_{it} + \gamma_0 \text{kids}_i + \gamma_1 \text{post86}_t + \gamma_2 (\text{kids} \times \text{post86})_{it} + \varepsilon_{it},$$

where  $\mathbf{Z}$  is a vector of demographic variables (with all the variables from the specification in column (5) of Table III),  $\text{kids}$  equals one for unmarried women with children, and the key coefficient is  $\gamma_2$ , the coefficient on the  $\text{kids} \times \text{post86}$  interaction. When we examine the distribution of hours conditional on hours exceeding zero, we are implicitly assuming that any EITC-caused increase in participation in the post-1987 period did not alter the hours distribution. We choose not to impose a selection model on the data for two reasons. First, to identify a selection model, we would need a policy shift that affects participation separately from hours of work. TRA86 does not provide us with such a shift. Therefore, any attempt to estimate a selection model would be heavily dependent on the specification chosen. Second, recent research suggests that inferences in labor supply models are extremely sensitive to the model chosen [Mroz 1987; Zabel 1993]. Our failure to account for new participants should bias upward our estimates of the reduction in hours due to the EITC (i.e., make them less negative). New participants are likely to enter the labor force with earnings and hours below what we predict from their exogenous characteristics. This will occur if unobserved factors (such as a greater taste for leisure) that explain their nonparticipation compared with others with the same exogenous characteristics also cause them to choose fewer hours of work.

In column (1) of Table V the coefficient on the interaction term is 25.22 (with a standard error of 15.18), suggesting that contrary to the predictions of theory, women with children increased their relative hours conditional on working by a small amount. In column (2) the sample is restricted to women with less than high school education. Here there is essentially no change in relative hours for single women with children. Further

---

creased dependent exemptions and standard deductions, reduced tax liability by more for head of household filers than for single filers. Thus, the tax bracket income effect works in the same direction as the EITC increase, and hours of work by household heads should fall relative to hours of work of single taxpayers.

## LABOR SUPPLY RESPONSE TO THE EITC

Observations	59,474	5700	67,097	9354	59,474	67,097		

Data are from survey years 1985–1987 and 1989–1991 of the March CPS. *Post86* equals one for tax years 1986, 1989, and 1990. *Kids* equals one if the tax filing unit contained at least one child. In addition to the variables shown, all regressions include year dummies for 1984, 1985, 1989, and 1990; variables for the number of children in the tax filing unit; age-cubed; interactions of age and nonwhite with *post86* and with *kids*; and a full set of state dummies. Standard errors are in parentheses. Regressions are weighted with CPS March supplement weights.

results, separating the sample into predicted income regions, find no evidence that the expansion of the phaseout region reduced hours of work for EITC eligible women [Eissa and Liebman 1995].

When we include the participation effect and look at total hours, the interaction coefficient increases from 25.22 to 37.37 for all women and from 2.98 to 83.83 for women with less than high school education. The 81-hour increase for the less than high school educated single women with children is consistent with our earlier finding that the participation rate for this population increased by 6.1 percentage points. Multiplying the increase in participation by average hours conditional on working for the less than high school population (1264) results in a total increase in hours of 77, quite close to the result from the total hours regression. Results for weeks worked, presented in columns (5) and (6) convey a similar story. There was little change in the conditional distribution of weeks worked after TRA86, and there was a larger increase in unconditional weeks worked.

#### *B. Why Do We Observe a Participation Effect But No Hours Effect?*

Economic theory suggests that the 1987 expansion of the EITC should have increased labor force participation and reduced the hours worked by EITC recipients who were already working. Our finding that the expansion did indeed increase labor force participation, but did not reduce hours worked is somewhat puzzling. We offer four explanations.

First, it is common for studies of labor supply to find that labor force participation responds more than hours of work to a change in the net wage [Mroz 1987; Zabel 1993; Triest 1992]. Second, there is strong evidence that many EITC recipients do not know that they receive the credit, and that even those who are aware of it do not understand how it works.<sup>18</sup> Taxpayers do not have to know about or understand the EITC for it to affect their labor force participation, they only have to perceive that they are better off while working than they were on welfare. Since almost

18. Interviews we conducted during August 1993 in Cambridge, Massachusetts, among potential recipients suggested virtually no awareness of the credit (see Eissa and Liebman [1993] for details). This observation was confirmed by the experience of one author (Liebman) as an IRS VITA volunteer in March and April 1994, which revealed that even past recipients were often unaware of the credit. More extensive interviews conducted in Chicago and described in Olson and Davis [1994] similarly found low awareness and understanding of the credit.

all recipients of the EITC receive the credit in a single payment as part of their annual tax refund check and not as part of their weekly paychecks, it is possible that recipients perceive it as a lump sum benefit. In this case the EITC would be predicted to have a positive impact on labor force participation, but only a small negative impact on hours worked via the income effect. Third, it is easier to measure participation than hours worked. If workers report round numbers for hours worked, it will take a large change in hours before the change is noticeable in the data. Fourth, since we observe both participation and hours of work increasing for single women with children relative to single women without children, it is possible that some unknown positive shock can explain our findings.

## VI. CONCLUSION

The 1987 expansion of the EITC and other aspects of the Tax Reform Act of 1986 reduced the relative tax liabilities of EITC-eligible household heads by up to \$1186 (1992 dollars). We estimate that this expansion increased labor force participation among all single women with children by up to 2.8 percentage points, from 73.0 to 75.8 percent. Among single women with children and less than high school education, the impact was even greater—6.1 percentage points. While there are a number of possible explanations for this evidence, we find the combined impact of the 1987 expansion of the EITC and the other provisions of TRA86 to be the most convincing explanation.

Between 1990 and 1996 the maximum earned income tax credit increased from \$1023 to \$3200 (1992 dollars) for a family with two children. Since our methodology did not allow us to estimate the underlying preference parameters of our sample, we cannot make precise predictions of the participation response to the more recent expansions. Our evidence suggests, however, that the recent expansions of the EITC will increase participation by female household heads. There may be decreasing returns to EITC expansions, however, if the nonparticipating population remaining after each increase is farther from the participation-nonparticipation margin.

When we apply our same methodology to hours of work, we find no evidence that the expansion of the EITC decreased hours of work for people already in the labor force. While our finding that the 1987 expansion of the EITC did not decrease hours of

work is encouraging, we think it will be important to reexamine this issue as the EITC expands. Awareness of the EITC is likely to increase as the maximum credit triples, and this could result in a greater sensitivity to the marginal tax rate imposed by the phaseout of the credit. In addition, since the lump sum payment of the EITC may explain the lack of hours responsiveness, it would be unwise to apply these results to other increases in marginal tax rates that operate through regular payroll deductions.

One final point is in order. A full evaluation of a transfer program like the EITC requires more than just an estimate of the distortionary impact of the program on the labor supply of transfer recipients. It also requires information on the value of the additional income received by program beneficiaries as well as the change in the amount of leisure that they consume. This must be balanced against the net income lost by taxpayers and the associated deadweight losses. Since both the welfare payments and the taxes involve deadweight losses, the desirability of the program depends on the weights assigned to changes in income at different income levels. A full comparison among alternative tax and transfer systems would also evaluate the technology of compliance and administration [Slemrod 1990]. This is particularly true in the case of the EITC where the tax system is performing functions that have traditionally been the responsibility of the welfare system [Alstott 1995].

Ultimately, the earned income tax credit is an income transfer program. Compared with other elements of the welfare system, the EITC appears to produce little distortion of work incentives. Therefore, if policy-makers want to redistribute income to the working poor and are comfortable with the trade-offs involved in using the tax system rather than the welfare system to administer transfers, the EITC seems to be a way to do so with minimal efficiency costs.

## Labor Market Institutions and their Effect on Labor Market Performance in OECD and European Countries

Kamila Fialová, June 2011

The aim of this technical note is to shed some light on relationship between labor market institutions and labor market outcomes in the member states of the Organization of Economic Cooperation and Development (OECD) in North America and East Asia; the New Member States of the European Union who are not members of the OECD (e.g. the Baltic states); countries in the European “Neighborhood” with aspire to accede to the EU (e.g. countries in the Western Balkans); and other European transitions countries (e.g. Ukraine, Moldova, and the Caucasus).

The analysis updates the econometric estimation techniques used in paper by Ondřej Schneider and Kamila Fialová "Labor Market Institutions and their Effect on Labor Market Performance in the New EU Member Countries" on an larger sample of countries. My approach utilizes panel estimation techniques on country level data and variables constructed to capture changes in key labor and social protection institutions over time. Estimations exploit cross-country and time series variability in key variables such as changes in the degree of unionization, the level of the minimum wage, employment protection legislation, and the level of the payroll tax for social insurance.

### **Methodology and data**

For my analysis, I use an econometric model inspired by recent empirical research and by economic theory, set out in Fialová and Schneider (2009). My approach utilizes two-stage least squares regression estimation with instrumental variables on pooled data. Standard panel estimation procedures (random or fixed effects estimation) were not employed for insufficient explanatory power of these models and/or too few data. The source of the data was mainly OECD with some supplements from IZA, WB and Eurostat for the explanatory variables, and the ILO and EBRD for explained variables.

Three data samples are examined:

- i. Sample 1: EU and OECD members in other regions (particularly North America and East Asia)*

Data come from the OECD and, therefore, cover only the OECD members. Time period concerned is 2001-2007.<sup>1</sup>

ii. *Sample 2: The EU15 and New Member States (NMS)*<sup>2</sup>

Source of the data is the OECD again. Utilization of the larger IZA sample was not possible due to the lack of relevant data. That means, the sample covers three NMS with data available only (Czech Republic, Hungary, Poland). Time period concerned is again 2001-2007.<sup>3</sup>

iii. *Sample 3: EU New Member States and aspirants in the European Neighborhood*

Data come from the IZA database and time period concerned covers years 1999, 2003, and 2007.<sup>4</sup> Nine NMS (data for Lithuania, Malta and Cyprus were not available) are covered.<sup>5</sup>

The model examines the impact of institutional factors on four indicators of labor market performance (Eurostat methodology): unemployment rate (*UR*), long-term unemployment rate (*LTUR*), employment rate (*ER*) and activity rate (*AR*). In line with the previous research, the dependent variables are represented in logs. The regression equation has the following form:

$$\ln X_{ti} = \alpha + \beta_1 EPL_{ti} + \beta_2 MW_{ti} + \beta_3 TU_{ti} + \beta_4 TAX_{ti} + \beta_5 ALMP_{ti} + \beta_6 UBRR_{ti} + \beta_7 INFL_{ti} + \beta_8 LEFT_{ti} + \varepsilon_{ti} \quad (1),$$

where *X* takes the form of *UR*, *LtUR*, *ER*, and *AR* in consequent regressions.

Explanatory variables are the following: *EPL* is the second version of the OECD employment protection legislation index covering a wide spectrum of employment protection policies. Minimum wage (*MW*) is a cluster variable constructed according to minimum wage level and its relative share on median wage in the economy. This variable was omitted in the analysis on Sample 3 due to unavailability of the data. The trade unions' power is represented by the trade union density (*TU*).<sup>6</sup> Tax system consequences are reflected by total tax wedge on

<sup>1</sup> The sample covers 24 countries: Australia, Austria, Belgium, Canada, Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Japan, Korea, the Netherlands, Norway, New Zealand, Poland, Portugal, Spain, Sweden, United Kingdom, and United States. 17 countries are classified as EU OECD, 7 countries as non-EU OECD.

<sup>2</sup> The new member states group ("NMS") for the purpose of this analysis generally consists of countries acceding to the EU in 2004 and 2007.

<sup>3</sup> The sample covers 18 countries: Austria, Belgium, Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, Ireland, Italy, the Netherlands, Norway, Poland, Portugal, Spain, Sweden, and United Kingdom. 15 countries are classified as old EU, 3 countries as NMS EU.

<sup>4</sup> For some countries, only some of these years with data available were covered.

<sup>5</sup> The sample covers 15 countries: Albania, Bulgaria, Czech Republic, Estonia, Croatia, Hungary, Kyrgyzstan, Latvia, Moldova, Macedonia, Poland, Romania, Slovenia, Slovakia, and Ukraine. 9 countries are classified as NMS EU, 6 countries as European Neighborhood.

<sup>6</sup> Trade union density refers to the share of workers who were trade union members. However, even if the density is rather low in some countries, it is a common practice to extend trade union agreements to nonunionized workers, thus covering a large share of employees in the economy (e.g., France and Spain). Thus, the real degree of collective bargaining coverage—the share of all salary earners whose wage is actually

labor (*TAX*).<sup>7</sup> Finally, to reflect the influence of labor market policies (LMP), expenditure on active LMP as % of GDP per percentage point of unemployment (*ALMP*) and initial unemployment benefits replacement rate (*UBRR*) is included. Active labor market policies expenditure is instrumented.<sup>8</sup> In the analysis on Sample 3, initial unemployment benefits replacement rate was replaced by two other indices available from IZA: the average unemployment benefit (*UNBEN*) and maximum duration of unemployment benefits (*UNBENDUR*) to reflect the effects of passive labor market policy spending.<sup>9</sup>

The actual rate of unemployment is utilized in the regressions, but labor market institutions affect rather the equilibrium unemployment. To reflect this, additional variable was used in the model—the change in the annual rate of inflation (*INFL*; see Nickell, 1997). This variable captures the influence of economic cycle and may be also considered an indicator of macroeconomic policy stance. Finally, unemployment level might be in reality also influenced by political preferences of governments and conflict of interest over the power resources (see for instance Korpi, 1991). To account for these political factors, one more variable was added in the regression model—the government orientation with respect to the economic policy. Variable *LEFT* is a dummy acquiring 1 for parties defined as communist, socialist, social-democratic or left-wing, where we expect greater orientation on social issues resulting in lower unemployment.<sup>10</sup> As economic policy takes time to influence labor market performance, we use the *LEFT* dummy with a one year lag.

The model analyzes mainly the basic correlations between labor market performance and labor market institutions. Its deeper explanatory power is rather limited, due to the lack of data on more countries and other relevant variables that might affect the dependent variables.<sup>11</sup> Moreover, only three NMS are covered in Sample 2 and, therefore, it is impossible to run a separate analysis for this group of countries. Generally, I examine only the differences in the role of institutions between the whole region and one particular sub-

---

determined by a collective agreement in a legal extension of bargained wage rates to nonunionized workers—would be a preferred indicator; unfortunately, such data is not available for the examined period and country sample.

<sup>7</sup> Total tax wedge on labor represents the combined central and sub-central government income tax plus employee and employer social security contribution taxes, as a percentage of labor costs, defined as gross wage earnings plus employer social security contributions; the tax wedge includes cash transfers (source: OECD). The indicator is calculated for a single individual without children, earning the average wage.

<sup>8</sup> This variable is endogenous because it relates the expenditure to the actual rate of unemployment. For this reason, we instrumented this variable by a new variable relating the expenditure to the average unemployment rate in a five-year period before the actual year.

<sup>9</sup> Average unemployment benefit is the average benefit as percentage of the average wage. This definition deviates from the estimates typically used by the OECD because OECD replacement rates are not very meaningful in the transition countries due to the caps on the size of the benefit in many countries. Maximum duration of unemployment benefits is defined as the period for which a person aged 40 years who has been employed for 22 years prior to unemployment receives unemployment benefits, wherever possible. The source of the data is IZA.

<sup>10</sup> The source of the data is the World Bank's database of political institutions; for details, see Keefer (2005).

<sup>11</sup> These are, for example, the role of product market reforms (Boeri, 2005; Griffith et al., 2006) or the importance of adverse economic shocks (Blanchard and Wolfers, 2000).

sample—and their implications for the other sub-sample—using a modified Chow test (see also Cazes and Nesporova, 2003).<sup>12</sup>

## Results

### UNEMPLOYMENT RATE (UR)

**Table 1. Regression estimation results – Unemployment rate**

#### • EU and OECD members in other regions

Active labor market policy expenditure, EPL, and tax wedge on labor have significant effects on UR in total OECD sample. While high taxation of labor and strict employment protection legislation tend to increase UR, larger active LMP expenditure offsets this effect and tends to reduce unemployment. Similarly, unemployment benefit initial replacement rate has a negative effect.

Estimation results for European countries only are similar to those for total OECD sample. Moreover, minimum wage exerts a negative effect on explained variable, which is, however, significant at 10% only. Furthermore, unemployment benefit initial replacement rate shows a significant negative influence.

<sup>12</sup> A modified version of the test hypothesis and statistics was used, because number of observations in the NMS group is smaller than the number of parameters,  $n_{NMS} < k$ , and thus I can not use the standard methods in this case. We test the hypothesis  $H_0: E(y | X; \beta_{OE}) = E(y | X; \beta_{NMS})$ . This is done by calculating the statistic

$$F = \frac{\frac{SSR_T - SSR_{OE}}{n_{NMS}}}{\frac{SSR_{OE}}{n_{OE} - k}} \approx F(n_{NMS}, n_{OE} - k).$$

Estimation results significantly differ for OECD countries outside Europe – minimum wage has a significant positive effect on UR; unemployment benefit initial replacement rate has a significant positive effect, too. Other labor institutions show insignificant effects in this group.

While the effects of active labor market policies, employment protection legislation and labor taxation are in line with economic theory and results of existing empirical research on this topic, the results for minimum wage and unemployment benefit initial replacement rate deserve more attention. My estimates show that the minimum wage tends to increase unemployment in non-European OECD sample, which is in accordance with the text-book pricing out effect. That means that it is mainly the Americans, Canadians, and North East Asians for whom the minimum wage might have adverse impact on labor market performance. In contrast, minimum wage tends to reduce unemployment in Europe, but this effect is significant at 10% only. Furthermore, the effect of unemployment benefit initial replacement rate is similarly ambiguous. While the generosity of unemployment benefits shows a negative effect on unemployment in Europe (might reflect its influence on matching processes), non-European sample recorded a positive sign of the regression coefficient, indicating a stimulating effect on unemployment.

To examine the potential differences in the role of explanatory variables between the two OECD sub-samples I applied modified Chow tests, as described above. Although some of the estimated coefficients suggest different behavior of these sub-regions, the tests' results did not reject the hypothesis of stability of regression coefficients between these two groups on the 5% significance level.

- *The EU15 and New Member States*

EPL, tax wedge on labor, active LMP expenditure and unemployment benefit initial replacement rate have significant effects on UR in total EU sample. While higher taxes on labor and stricter EPL increase UR, larger active LMP expenditure and higher unemployment benefit initial replacement rate have negative effects. The effect of active LMP expenditure is, however, significant at 10% only.

Estimation results for old European countries only are similar to those for total EU sample with an exception of active LMP expenditure, the effect of which becomes insignificant.

Estimation results significantly differ for new EU countries – minimum wage has a positive effect on UR; in contrast, higher trade union density has a negative effect, similarly to higher labor taxation. However, reliability of the model specification for this sample is lower due to low number of observations (21; 3 countries).

Again, the applied Chow tests' results did not reject the hypothesis of stability of regression coefficients between the two sub-regions on the 5% significance level.

- *EU New Member States and aspirants in the European Neighborhood*

Three labor institutions have a significant effect on UR in total sample: EPL, active LMP expenditure and average unemployment benefit. While EPL increases UR, active LMP expenditure and average unemployment benefit have negative effects.

Model specification on the two sub-samples (EU NMS and European Neighborhood countries) does not fit the data. All the regression coefficients are insignificant in sample of European Neighborhood countries. Trade union density has a significant coefficient in NMS sample, indicating a negative impact of trade union on unemployment level.

Similarly to the two previous cases, the applied Chow tests' results did not reject the hypothesis of stability of regression coefficients between the two sub-regions on the 5% significance level.

## LONG-TERM UNEMPLOYMENT (LTUR)

**Table 2. Regression estimation results – Long-term unemployment rate**

Note: \*\*\* significant at 1% level, \*\* significant at 5% level, \* significant at 10% level. Regression method: pooled two-stage least squares procedure with instrumental variables on panel data; robust standard errors utilized.

- EU and OECD members in other regions

Tax wedge on labor, minimum wage and unemployment benefit initial replacement rate have significant effects on LTUR for total OECD sample. While taxes and minimum wage tend to increase LTUR, unemployment benefit initial replacement rate has a negative effect. (Both minimum wage and unemployment benefit initial replacement rate showed insignificant effects for total unemployment rate.) The effects of other labor institutions are insignificant.

Estimation results for European countries only show significant effects of a slightly different set of institutional variables. While the stimulating effect of labor taxation on long-term unemployment was confirmed, it tends to be offset by negative effects of active labor market policy expenditure and higher degree of trade unionization (the effect of trade unions was insignificant for total unemployment).

Estimation results significantly differ for OECD countries outside Europe – minimum wage has a significant positive effect on LTUR and EPL exerts a negative influence, which is, however, significant at 10% level only. All other labor institutions show insignificant effects in this group.

Again, European and non-European OECD members seem to have different drivers of the long-term unemployment. While high labor taxation is the main issue in Europe, other OECD members seem to suffer the most from the minimum wage legislation.

Similarly to the previous analysis of the unemployment rates, the applied Chow tests' results did not reject the hypothesis of stability of regression coefficients between the two sub-regions on the 5% significance level.

- *The EU15 and New Member States*

Tax wedge on labor and trade union membership have significant effects on LTUR in total EU sample. While taxes increase LTUR, trade union membership has a negative effect.

Estimation results for old European countries only are similar to those for total EU sample.

Estimation results significantly differ for new EU countries – minimum wage has a significant positive effect on LTUR; in contrast, greater trade union density and higher taxation of labor exert negative effects. Active labor market policy expenditure tends to have a positive effect, significant at 10% only. Still, reliability of the model specification for this sample is lower due to low number of observations (21; 3 countries).

Again, the applied Chow tests' results did not reject the hypothesis of stability of regression coefficients between the two sub-regions on the 5% significance level.

- *EU New Member States and aspirants in the European Neighborhood*

Reliability of model estimates on this sample is rather problematic due to a very low number of observations. Due to this limitation, the results must be taken with caution.

No labor institutions but active labor market policy expenditure have significant effect on LTUR in total sample. Active labor market policy expenditure tends to reduce long-term unemployment.

The results change modestly when EU NMS only are considered: active LMP expenditure holds its significant negative effect and trade union density turns out to have a significant negative effect, too.

There is not enough data for model specification on the European Neighborhood countries sub-sample (one country).

## EMPLOYMENT RATE (ER)

**Table 3. Regression estimation results – Employment rate**

	OECD			European Union			NMS EU+European Neighborhood		
	Total OECD	EU OECD	Total	Total	Total	NMS EU	Total	NMS EU	Neighborhood

Chow test F p-value	0.5037			0.9999			0.8499		

Source: OECD, IZA, World Bank, ILO, EBRD, own calculations

Note: \*\*\* significant at 1% level, \*\* significant at 5% level, \* significant at 10% level. Regression method: pooled two-stage least squares procedure with instrumental variables on panel data; robust standard errors utilized.

- *EU and OECD members in other regions*

All labor institutions but the minimum wage have significant and similar effects on ER in both total OECD sample and EU OECD sub-sample. EPL and labor taxation tend to diminish ER, while active labor market programs, trade unions and unemployment benefit initial replacement rate have stimulating effects.

The situation differs in non-EU OECD sub-sample, where EPL, taxation of labor and trade unions act similarly to total sample and EU sub-sample, but unemployment benefit initial replacement rate has an opposite effect on ER (negative). This means that while generosity of passive labor market programs seem to stimulate employment in Europe (might be explained by improved efficiency of matching and functioning of the labor market), it tends to depress employment in non-EU OECD countries (might be explained by abuse of the programs, increased reservation wage of the unemployed etc.). The coefficient of the minimum wage becomes significant with a negative sign in this sub-sample, indicating a diminishing effect on employment. Active labor market programs have insignificant influence on employment level.

Similarly to the previous analysis of unemployment and long-term unemployment, the applied Chow tests' results did not reject the hypothesis of stability of regression coefficients between the two sub-regions on the 5% significance level.

- *The EU15 and New Member States*

All labor institutions exert significant and similar effects on ER in both total EU sample and old EU sub-sample. EPL, minimum wage and labor taxation tend to diminish ER, while active labor market programs, trade unions and unemployment benefit initial replacement rate

have stimulating effects. The coefficient of the minimum wage is, however, significant at 10% only.

On the other hand, taxation of labor has a positive effect on ER in the NMS sub-sample, similarly to trade unionization. Minimum wage tends to have a diminishing effect on ER here. Both passive and active labor market policy indicators and employment protection legislation are insignificant in this sub-sample. However, reliability of this model specification for this sample is lower due to low number of observations (21; 3 countries).

Again, the applied Chow tests' results did not reject the hypothesis of stability of regression coefficients between the two sub-regions on the 5% significance level.

- *EU New Member States and aspirants in the European Neighborhood*

The model does not fit the data for the total sample and for the European Neighborhood sub-sample – no explanatory variable is significant.

Two labor institutions have a significant impact on ER in EU NMS sub-sample: trade union density significantly increases the employment rate; in contrast, duration of unemployment benefits payment significantly reduces employment.

Again, the applied Chow tests' results did not reject the hypothesis of stability of regression coefficients between the two sub-regions on the 5% significance level.

## ACTIVITY RATE (AR)

**Table 4. Regression estimation results – Activity rate**

	OECD			European Union			NMS EU+European Neighborhood		
	Total OECD	EU OECD	non-EU	Total EU	Old EU	NMS EU	Total	NMS EU	Neighborhood
ALMP	0.072 ***	0.101 ***	-0.017	0.091 ***	0.117 ***	-0.081	-0.077	-0.036	-1.257

Prob > F	0.000	0.000	0.000	0.000	0.000	0.000	0.018	0.000	0.081
Chow test F p-value	0.5648			0.9999			0.8413		

Source: OECD, IZA, World Bank, ILO, EBRD, own calculations

Note: \*\*\* significant at 1% level, \*\* significant at 5% level, \* significant at 10% level. Regression method: pooled two-stage least squares procedure with instrumental variables on panel data; robust standard errors utilized.

- *EU and OECD members in other regions*

All labor institutions but minimum wage have significant effects on AR in total OECD sample. EPL and labor taxation tend to diminish AR, while active labor market programs, trade union density and unemployment benefit initial replacement rate have stimulating effects.

In the EU sub-sample, the results are quite similar with the exception of two variables – while the EPL becomes insignificant, minimum wage turns out to be significant with a negative effect on AR.

The significance of the EPL coefficient in the total sample was probably driven by non-EU OECD sub-sample, where EPL exerts a significant negative effect on AR. Further, minimum wage and unemployment benefit initial replacement rate have negative effects here, while trade unions have an opposite, diminishing effect. Active labor market programs and labor taxation are insignificant for explaining the heterogeneity in activity rates in non-European OECD countries.

The applied Chow tests' results did not reject the hypothesis of stability of regression coefficients between the two sub-regions on the 5% significance level.

- *The EU15 and New Member States*

All labor institutions but EPL have significant and similar effects on AR in total EU sample. Minimum wage and labor taxation tend to diminish AR, while active labor market programs, trade unions and unemployment benefit initial replacement rate have stimulating effects.

The old EU sub-sample gives very similar results, with a little difference in unemployment benefit initial replacement rate becoming significant at 10% only and EPL turning out to have a significant positive effect on AR.

In the NMS sub-sample, taxation of labor has an opposite, positive effect on ER, similarly to trade unionization and unemployment benefit initial replacement (significant at 10% only). Minimum wage tends to have a diminishing effect on AR again. But once again, reliability of this model specification for this sample is lower due to low number of observations (21; 3 countries).

Again, the applied Chow tests' results did not reject the hypothesis of stability of regression coefficients between the two sub-regions on the 5% significance level.

- *EU New Member States and aspirants in the European Neighborhood*

One labor institution only has a weakly significant effect on AR in total sample: trade union membership, which tends to exert a negative effect on activity.

In the EU NMS sub-sample, tax wedge on labor significantly depresses activity rate, while trade union density tends to stimulate it.

Model specification on the European Neighborhood sub-sample does not fit and all the coefficients are insignificant.

Finally, the applied Chow tests' results did not reject the hypothesis of stability of regression coefficients between the two sub-regions on the 5% significance level.

## **Conclusions**

Several estimation approaches for different data samples and explanatory variables were used to analyze the impact of labor market institutions on the labor market outcomes in European and OECD countries. Previous research on this topic indicated that the relationship is not straightforward or statistically very robust (see Fialová and Schneider, 2009). Institutions are difficult to define, measure, and compare between countries, and their effect may change over time. This technical note, nevertheless, analyzes the impact of labor market institutions in above-mentioned regions and finds that they do affect major labor market indicators. My findings correspond generally with the previous empirical studies of Cazes and Nesporova (2003) and Nickell (1997) and with major theoretical concepts on this issue.

While the estimations applied on the OECD and European Union samples give consistent and robust results, results of the model applied on the European Neighborhood sample suffer from limited robustness due to limited number of observations available with a relatively many RHS variables. Separate analysis of the EU NMS is a similar case (3 countries only). Therefore, the results for these groups of countries must be taken with caution.

When analyzing the pattern of differences in the unemployment rates, all three samples indicate a positive effect of employment protection legislation on increasing unemployment in examined countries. Similar effect was documented for labor taxation and the minimum wage, although the robustness of these results is weakened by insignificance of the coefficients in some of the samples and negative estimated coefficients of labor taxation on unemployment in European NMS and of the minimum wage on unemployment in EU OECD countries (significant at 10% level only). Furthermore, active labor market policy expenditure tends to reduce unemployment significantly. More generous unemployment benefits mostly tend to influence the unemployment rate negatively with an exception of the non-EU OECD countries. The effect of higher trade unions' power was mostly insignificant in presented results.

While the effects of active labor market policies, employment protection legislation and labor taxation are in line with economic theory and results of other empirical research on this topic, the results for minimum wage and unemployment benefit initial replacement rate deserve a more detailed explanation. The results show that the minimum wage tends to increase unemployment in non-European OECD sample, which is in accordance with the text-book pricing out effect. That means that it is mainly the Americans, Canadians, and North East Asians for whom the minimum wage might have adverse impact on labor market performance. In contrast, minimum wage tends to reduce unemployment in Europe, but

this effect is significant at 10% only. Furthermore, the effect of unemployment benefit initial replacement rate is similarly ambiguous. While the generosity of unemployment benefits shows a negative effect on unemployment in Europe (might reflect its positive influence on matching processes), non-European sample recorded a positive sign of the regression coefficient, indicating a stimulating effect on unemployment.

Taxation of labor showed a positive effect on long-term unemployment across the OECD and EU samples with an exception of EU NMS, where a negative effect seems to be the case (although reliability of this result is limited due to low number of observations). Minimum wage tends to have a significant stimulating effect on long-term unemployment. Again, European and non-European OECD members seem to have different drivers of the long-term unemployment. While high labor taxation is the main issue in Europe, other OECD members seem to suffer the most from the minimum wage legislation. Further, trade union density tends to significantly reduce long-term unemployment in European Union. This might be connected with a high degree of coordination and centralization of the trade unions' claims, which are typical for European countries. The effect of employment protection legislation was generally insignificant in my estimations. Similarly, the effect of unemployment benefits initial replacement rate was mostly insignificant with an exception of a negative effect reported in total OECD sample. Active labor market policy expenditure has an insignificant effect, too.

Turning to explaining the variation in labor supply, the model specification applied on employment rates was able to explain a larger part of the heterogeneity when compared with its explanatory power in the case of both unemployment indicators. Active labor market policy expenditure tends to significantly stimulate employment. Similar effect was registered for trade union density, which might be again connected with the high degree of centralization and coordination. Generosity of passive labor market programs also tends to stimulate employment with an exception of non-EU OECD countries, which registered an opposite effect of this relationship. On the other hand, strictness of employment protection legislation affects employment negatively. Similarly, high labor taxes discourage employment in all the sub-samples but NMS EU. Minimum wage exerts a negative impact on employment in the non-EU OECD and NMS EU sub-samples.

As far as the differences in activity rates are concerned, both strict employment protection and high taxation generally discourage economic activity in examined countries. However, there are two exceptions: firstly, labor taxes tend to support economic activity in NMS EU, which might be, however, considered an unreliable result due to low number of observations. Secondly, EPL shows a positive effect in old European countries. Active labor market programs and trade unions' activity stimulate labor participation. Generosity of passive labor market programs has an ambiguous impact: while it tends to increase economic activity in Europe, the effect on non-European OECD countries is opposite again. The negative effect of the minimum wage seems counterintuitive, but might be explained by

its negative impact on employment. Workers, who lost their jobs as a result of introduction of the minimum wage, might be discouraged from participating in the labor market at all (especially the young and women, who are usually expected to be hit the most).

The results of applied Chow tests examining the potential differences in the role of explanatory variables between the particular sub-samples are inconclusive. Generally, I was not able to reject the hypothesis of stability of regression coefficients between the examined groups of countries in all tested models. While some of the estimated coefficients suggest different behavior, the available data did not allow to study this issue in detail.

### Abstract

The unemployment rate in Estonia rose sharply in 2010 to one of the highest levels in the EU, after the country entered a severe recession in 2008. While the rate declined relatively rapidly in 2011, it remained high especially for the less educated. In 2009, the Employment Contract Law relaxed employment protection legislation and sought to raise income protection of the unemployed to facilitate transition from less to more productive jobs while mitigating social costs. Utilizing a search model, this paper shows that increasing further labour market flexibility through reducing the tax wedge on labour would facilitate the structural transformation and reduce the long-term unemployment rate. Linking increases in unemployment benefits to participation in job search or training programmes would improve the unemployed workers' incentives to search for jobs or retrain and the medium term labour market outcomes. Social protection schemes for the unemployed should be also strengthened as initially intended to give the unemployed sufficient time to search for adequate jobs or retrain for new opportunities.

<sup>1</sup> The authors thank Jan Svejnar, Andreas Wörgötter and participants at the 69<sup>th</sup> IAES Conference (Prague) and the 2011 ACES/ASSA meetings (Denver) for helpful comments. We also thank Stefano Scarpetta for insightful suggestions on the first draft. The paper substantially expands the analysis from the 2009 OECD Survey of Estonia. Views expressed are those of the authors and do not necessarily reflect those of their institutions of affiliation.

## 1. Introduction

Following a deterioration during the transition to a market economy and the Russian crisis in the 1990s, the labour market outcomes in Estonia improved markedly by the end of 2007. The employment rate exceeded the EU-15 average and participation rates increased. After entering a recession in 2008, Estonia's unemployment rate escalated from 4.1 percent in December 2007 to 19.8 percent in June 2010 – one of the highest levels in the European Union. Even though real GDP grew by almost 9 percent in 2011, unemployment remained about 13 percent. With high unemployment and the large share of low-value added non-tradable sectors including construction, a pressing issue for policymakers became reallocating workers across jobs and sectors to more productive activities, while mitigating fiscal and social costs. Flexibility of the labour market, together with job creation, became important for strong recovery and medium-term outcomes.<sup>1</sup> At the same time, adequate social support for the unemployed was needed to ensure their minimum living standards and opportunities to improve livelihoods.

Applying the search frameworks of Mortensen and Pissarides (1999) and Van Ours (2007) to Estonia, this paper examines the impact of labour market reforms adopted in the country in 2009 and those expected in 2013, in particular deregulating employment protection and raising unemployment insurance.<sup>2</sup> The analysis suggests that labour market adjustment from unemployment to increased high value-added activities would be eased if: (i) increases in unemployment benefits were made conditional on participation of the unemployed in active labour market programs, especially retraining and job search; (ii) the employers' social security contributions were reduced, and (iii) increases in minimum wages were contained. The reduction of labour taxation, especially for low-wage workers, could also stimulate job creation.

A simulation exercise based on the labour market matching model with active labour market policies of Van Ours (2007) illustrates that *i*) linking unemployment benefits to participation in active labour market programmes reduces unemployment if accompanied by effective job creation incentives; *ii*) in contrast, lowering minimum wages hampers incentives of the low-wage unemployed to search for jobs, but makes firms more willing to hire, with an ambiguous impact on the overall employment; *iii*) cuts in firms' social security contributions stimulate firms' incentives to hire.

The paper is organised as follows. Section 2 outlines the main features of the Estonian labour market, and Section 3 presents the search matching model and policy simulations. Section 4 compares the results for Estonia with some stylised facts for OECD countries, while Section 5 concludes.

## 2. Main characteristics of the Estonian labour market

From 2000 to early 2008, Estonia's labour market outcomes improved markedly: the unemployment rate dropped to close to 4 percent in 2008, its lowest point in 16 years, with long-term and very long-term unemployment rates also falling steadily (Figure 1). At the same time, the employment rate and labour force participation increased. While aggregate outcomes improved, large inequalities persisted among regions, ethnic groups, and workers with different skill levels, with unemployment being particularly high among unskilled workers.

The economic boom, reflected also in eventual skill shortages, led to excessive real wage increases during 2005-07, both in the private and public sectors. Subsequently the gap between real wages and real GDP widened. After having risen sharply to 19.8 percent after Estonia fell into a deep recession in mid-2008, the

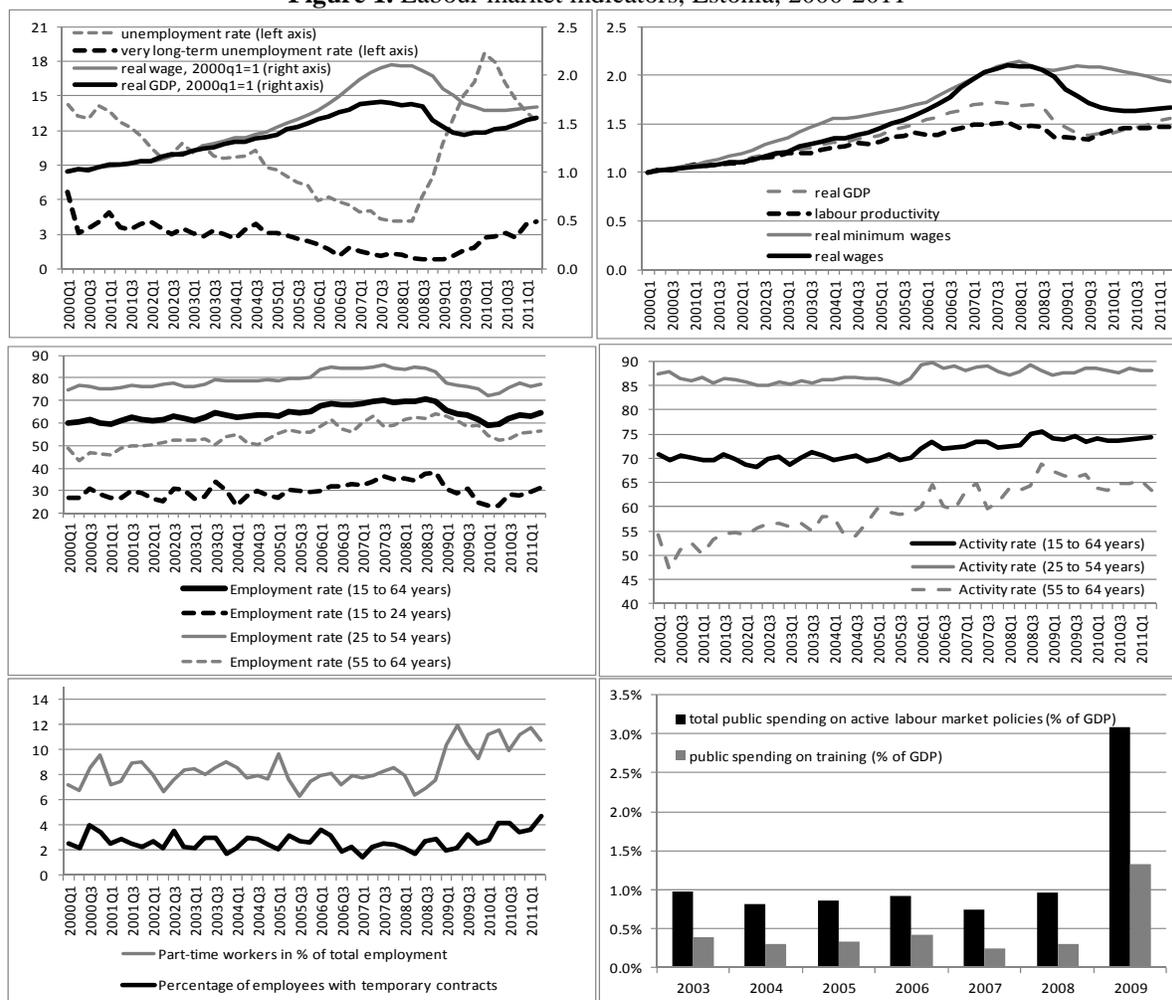

---

<sup>1</sup> The need for labour market flexibility is further underscored by the currency board arrangement.

<sup>2</sup> In July 2009, the Employment Contracts Act became effective, which aimed at increasing the labor market flexibility by reducing costs of lay-offs and security through raising unemployment insurance. However, most of the measures aiming at raising security were postponed until 2013 (Leetmaa and Nurmela, 2011).

unemployment rate has been declining and reached 13.3 percent in the third quarter of 2011. The structure of employment has also changed, with the share of workers on part-time and temporary contracts gradually rising since 2008 (Figure 1). Differences across skill levels remained: in Q2, 2010 unemployment rate was 32.7 percent for the uneducated population relative to the 18 percent overall rate (OECD, 2011).

**Figure 1. Labour market indicators, Estonia, 2000-2011**

Source: Authors' calculations based on data drawn from Eurostat and OECD.

Note: Unemployment rate is calculated using Labour Force Survey data. Real wage is the nominal wage divided by the level of the consumer price index.

Besides high unemployment, especially among the less educated workers, the Estonian labour market has the following structural features.

First, it is characterised by a high degree of wage flexibility<sup>3</sup> and almost fully decentralised wage setting, with wages being determined mostly within firms. Exceptions are the setting of the minimum wage, wages in the civil service sector set by government regulations, and wages in selected heavily unionized

<sup>3</sup> Flexibility reflects how quickly the labour markets adjust to shocks (Pissarides, 1997). Four elements are typically discussed: *i*) numerical flexibility, *ii*) working time; *iii*) functional flexibility, and *iv*) the rate at which nominal and real wages respond to changes in supply and demand (Eamets and Paas, 2007).

industries (e.g., textiles).<sup>4</sup> According to Rõõm (2008) and Maivali and Lubenets (2007), wage adjustments in Estonia are frequent, with substantial cyclical fluctuations and sizeable sectoral dispersion. Yet, wage flexibility declined during the boom period: while until 2004 wage increases reflected closely productivity gains (Babecký, 2008; Rõõm, 2008), during 2005-07 real wage increases were largely in excess of labour productivity growth due to labour and skill shortages resulting from rising demand<sup>5</sup>. At 20 and 40 percent respectively, Estonia's 2007 growth in average earnings (including bonuses and overtime) was among the highest and the increase of the civil sector wage was the highest in the EU (Figure 1).

According to a survey by Dabusinskas and Rõõm (2011), wages were downwardly flexible during the crisis especially relative to other European countries. Specifically, in summer 2009, around 46 percent of Estonian firms already cut wages of their workers and another 40 percent intended to do so. Overall, 30 percent of the labour force were impacted by wage cuts, a far larger share than in other countries surveyed.

Second, until 2009, *Employment Protection Legislation (EPL)* in Estonia was more rigid than in other Central European countries or the OECD average (Table 1). The rigidity stemmed from: regulation of regular contracts, notably from long notice periods for workers with short tenure; narrow definition of unfair dismissal; and the right to re-employment or high compensation for unfair dismissal.<sup>6</sup> EPL was eased in 2009: the new Employment Contract Act deregulated comprehensively regular contracts, including i) a reduction in the notice period for redundancy to 15–90 working days, depending on the length of employment; ii) a cut in severance payments, costs of which are shared by the employer and the Unemployment Insurance Fund; and iii) an easing of dismissals and hiring, which facilitates overall mobility and job search of the new job market entrants (OECD, 2004). Estonia's EPL thus became slightly less stringent than in the euro area (Dabusinskas and Rõõm, 2011).

To address concerns about reduced employees' security due to a lighter EPL, the income protection for the unemployed was to be enhanced through raising the unemployment benefit replacement rate and easing the eligibility for unemployment insurance. Specifically, the unemployment income replacement rate was to be raised from 50 to 70 percent during the first 100 days of unemployment, and from 40 to 50 percent afterwards. Those leaving their jobs voluntarily were also to receive unemployment insurance benefits. However, adoption and implementation of these measures have been postponed to 2013 (Leetmaa and Nurmela, 2011). This delay is in contrast with measures of some other European countries that increased unemployment support to safeguard adequate living standards.<sup>7</sup>

Third, before the 2007-08 crisis, expenditures on active labour market policies (ALMPs), as a share of GDP, were very low in comparison to a European or OECD average. ALMPs thus played a minimal role in facilitating workers' employment. Incentives for unemployed workers to search or undergo training were also low. As shown in Figure 1, spending on ALMPs increased markedly to above 3 percent in 2009 from below 1 percent of GDP in 2008.

---

<sup>4</sup> Overall though, the rate unionization and the use of collective bargaining coverage in the private sector of the Estonian economy are very low (12 and 9 percent, respectively). Collective bargaining is almost irrelevant for the wage setting process in the overall economy (Dabusinskas and Rõõm, 2011).

<sup>5</sup> A key factor behind the wage flexibility was a widespread use of performance-related bonuses. The 2007 survey of private firms in industry, constructions, services, and trade revealed that about two thirds of firms use bonuses, and their share in the wage bills ranged from 14% in industry to 23% in trade (Dabusinskas and Rõõm, 2008).

<sup>6</sup> Yet, EPL regulations were not adhered to in practice (Eamets and Masso, 2005).

<sup>7</sup> As a response to the global crisis, several OECD countries extending the coverage (Sweden) or duration of their unemployment benefits (Portugal, United States).

Fourth, the minimum wage, determined annually by agreement between trade unions and representatives of employers is low, measured by the ratio of the minimum wage to the average wage at around 30 percent. Yet it was increasing very rapidly until 2007. The increases in the minimum wage in these years exceeded both average real wage growth and labour productivity growth, thus pricing out of jobs low-income workers for whom the minimum wage may constitute a binding constraint. The minimum wage is determined annually at the centralised level and covers all employees. According to Rõõm (2008) and other estimates, approximately 6 percent of private sector workers in Estonia earned the minimum wage in 2008. But the influence of the minimum wage on wage formation goes beyond these six percent – for example, in some cases of unionized enterprises (e.g., textile), minimum wages constitute a basis from which wages of all workers are derived and stipulated in collective agreement.

Finally, Table 1 shows the very high tax wedge on labour, which stands in contrast to a modest overall tax burden on income tax and especially on capital gains: Overhead costs, comprising social contribution tax levied on employers accounted for almost 40 percent of wages in 2006 and remained at that level in 2011. The tax wedge is especially high when compared to OECD countries such as Ireland, the USA or the United Kingdom, whose labour markets are similar to Estonia's (OECD, 2011).

**Table 1. Main characteristics of the Estonian labour market in an international comparison**

	year	Estonia	OECD		
			AVERAGE	MAX	MIN

### 3. A matching model with active labour market policies: application to Estonia

#### 3.1. The model

To illustrate the likely medium-term outcomes of reforming labour market institutions, changes in active labour market programmes (ALMPs), unemployment benefits, minimum wages, and employers' social security contributions are examined in a standard search model, applied to Estonia. Specifically, the model outlined below is a somewhat modified version of Van Ours (2007), which extends the framework of Mortensen and Pissarides (1999) by adding participation in job search and/or training programmes. The application below focuses on the effect of labour market reforms on incentives for the unemployed to search for jobs or to participate in training programmes and for firms to create jobs.

In the model, workers can be either employed in the private sector or unemployed. Unemployed workers receive benefits  $b$ , value their leisure as  $l$ , and search for jobs or put effort in training with intensity  $x \geq 0$  while incurring cost  $k(x) = \frac{x^2}{2\gamma}$ , where  $\gamma > 0$ . Employed workers receive wage  $w$ . Firms post vacancies to fill jobs at cost  $c$ . Each filled job results in output  $y$ , with  $y > w$ . The key component of the model is a matching function  $A = A(xu)^{1-\eta} v^\eta$ , where  $A > 0$  denotes the efficiency of the matching and  $\eta \in (0,1)$  is the elasticity of matches with respect to vacancies. The workers' search/training effort results in job offers,

which arrive at rate  $\mu(\theta)x = A\theta^\eta$ , where  $\theta = \frac{v}{xu}$  denotes the ratio of vacancy rate,  $v$ , to effective unemployment rate,  $xu$ , *i.e.* it describes the tightness of the labour market from firms' perspective. Conversely, firms fill their vacancies at rate  $\frac{\mu(\theta)}{\theta} = A\theta^{\eta-1}$ . All job matches dissolve at rate  $\delta$ , and firms pay to each laid-off worker a severance payment  $K$ . The employment rate,  $e$ , and unemployment rate,  $u$ , change according to:

$$\dot{e} = A\theta^{\eta-1}v - \delta e \quad (1)$$

$$\dot{u} = \delta e - A\theta^\eta xu \quad (2)$$

With normalizing the labour force to 1, that is  $1 = e + u$ , the steady state equilibrium unemployment decreases with search/training effort and the tightness of the labour market:

$$\bar{u} = \frac{\delta}{\delta + A\bar{\theta}^\eta \bar{x}} \quad (3)$$

To illustrate the impact of mandatory participation in ALMPs on workers' search/training effort, a scenario where all unemployed workers can receive unemployment benefit only if they participate in the job search assistance or retraining programme is considered. Participation in such programme lowers the value of leisure for the unemployed by fraction  $z \in (0,1)$  and their search cost by a fraction  $\sigma \in (0,1)$ . Workers accept jobs only when the value of employment,  $V_E$ , exceeds the value on unemployment,  $V_U$ :

$$\rho V_U = \max_x \left( b + (1-z)l - \frac{(1-\sigma)x^2}{2\gamma} + A\theta^\eta x(V_E - V_U) \right) \quad (4)$$

$$\rho V_E = w + \delta(V_U - V_E) \quad (5)$$

where  $\rho$  is the discount rate. Denoting  $J_E$  as value of filled job and  $J_V$  as value of vacancy, the corresponding Bellman equations are:

$$\rho J_E = y - (1+\tau)w + \delta(J_V - J_E - K) \quad (6)$$

$$\rho J_V = -c + A\theta^{\eta-1}(J_E - J_V) \quad (7)$$

Where  $y$  is the output from the filled vacancy,  $w\tau$  is the social employers' contribution tax paid, and  $K$  is the severance cost incurred by the firm. Under the standard assumption of free entry into the job creation, value of posting a vacancy is  $J_V = 0$ . (6) and (7) can therefore be reduced to:

$$\frac{y - (1+\tau)w - \delta K}{\rho + \delta} = \frac{c\theta^{1-\eta}}{A} \quad (8)$$

The optimal search/training intensity  $x$  can be derived directly from (4):

$$\bar{x} = \frac{\gamma}{(1-\sigma)} A \theta^n (V_E - V_U) \quad (9)$$

The search/training effort rises with higher loss of leisure due to participation in the ALMP programme.

To complete the characterization of unemployment outlined in (3), a solution for the tightness of the labour market,  $\theta$ , needs to be obtained through deriving wages. Regarding wage determination, the model deviates from the standard assumption of Nash wage bargaining. Instead, it assumes that flexible wages move with productivity changes:  $w = \phi y$ , where  $\phi \in (0,1)$ , consistent with the empirical evidence (Dabusinskas and Rõõm, 2011; Babecký, 2008; and Rõõm, 2008).

### 3.2. Comparative statics

The comparative statics relevant in the Estonian context are:

**Table 2. Comparative statics in the job search-matching model**

Effect of an increase in:	On search effort of the unemployed $x$	On unemployment rate $u$
Reduced utility from less leisure $z$	+	-
Search cost reduction $\sigma$	+	-
Matching efficiency $A$	+	-
Minimum wage $w^{\min} > \phi y$	+	+
Unemployment benefit $b$	-	+
Payroll tax $\tau$	-	+
Separation rate $\delta$	-	+

The search/training effort of the unemployed rises with effective job search and training programmes, lower search/training cost, improved matching efficiency, and reduced separation rate. The ALMPs can improve matching efficiency (by dissemination of information) as well as reduce search/training cost and separation rate.

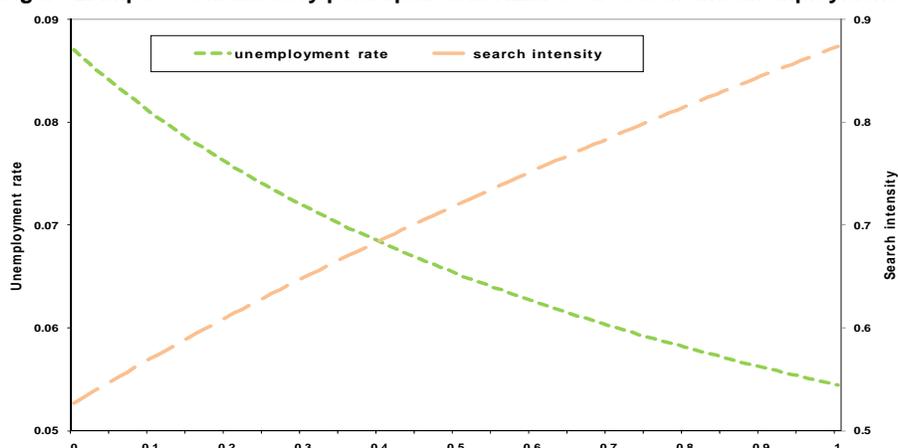

### 3.3. Simulation results

The model is simulated using quarterly parameters from existing studies and the Estonian labour market data. Parameters are specified as follows:

**Table 3. Parameters of the model**

Parameter	Definition	Value	Source
$\gamma$	Output (productivity)	1	Van Ours (2007)
$\delta$	Separation rate (quarterly)	0.045	Statistics Estonia
$\tau$	Social security contribution (% of wage)	0.33	Ministry of Finance, the Republic of Estonia
$c$	Cost of posting vacancies	6	Set so that vacancy-unemployment ratio corresponds to the steady state value of 0.8 (based on past outcomes)
$\eta$	Elasticity of matching to Vacancies	0.5	Van Ours (2007)
$\rho$	Discount rate	0.025	Van Ours (2007)
$A$	Efficiency of matching Function	1	Van Ours (2007)
$b$	Unemployment benefit, Including value of leisure	0.4	Shimer (2005)
$b_u$	Replacement rate (part of $b$ )	0.25	Set at the current rate of 50%
$\gamma$	Cost of job search	0.9	Set to obtain steady state unemployment of 6.5%
$\phi$	Share of wage in output	0.5	Share of compensation of employees in GDP

Figures below illustrate that participation in active labour market programmes, especially job search activation or training programmes, would increase workers search or training efforts through two channels: 1) by reducing the value of leisure and hence increasing relative payoffs from working; and 2) by increasing workers' chance of exiting unemployment. As a result of workers' increased search or training effort, unemployment would decline through both channels. Regarding effective application, programmes encouraging job search would help speed up recovery from cyclical unemployment where new jobs are created in the same sectors and hence workers can draw on existing skill. In contrast, training programmes would typically facilitate structural change, where new jobs are created in new sectors (for example in services rather than construction).<sup>8</sup>

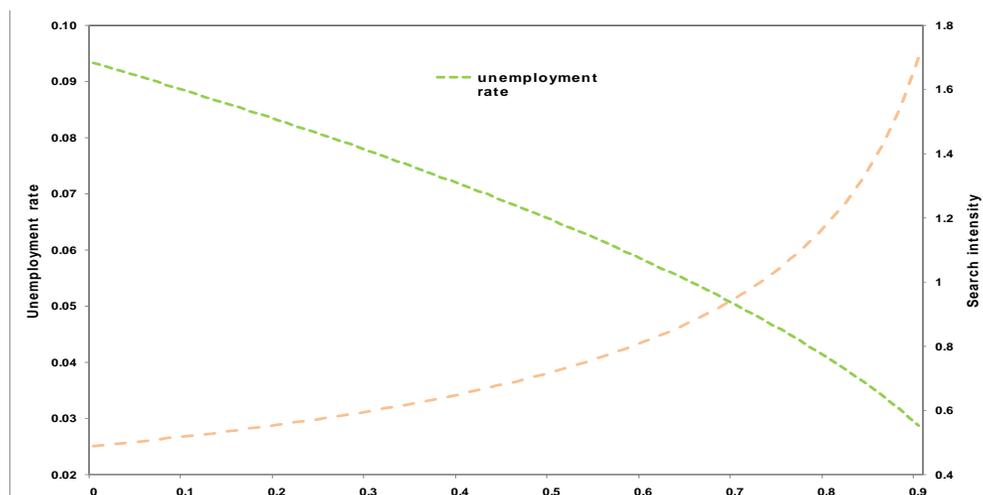

**Figure 2. Impact of mandatory participation in ALMPs on search and unemployment<sup>9</sup>**

Note: Unemployment rate is number of unemployed as % of labour force. For units of consumption good, the price of the consumption good is normalised to one. Mandatory participation represents foregone leisure.

<sup>8</sup> Training programs can also help the unemployed workers maintain or improve the existing skills.

<sup>9</sup> All simulations (Figure 2 – 5) focus on the impact of labour market policies on search effort, that is participation in job search programs. Results apply to participation in training programs as well.

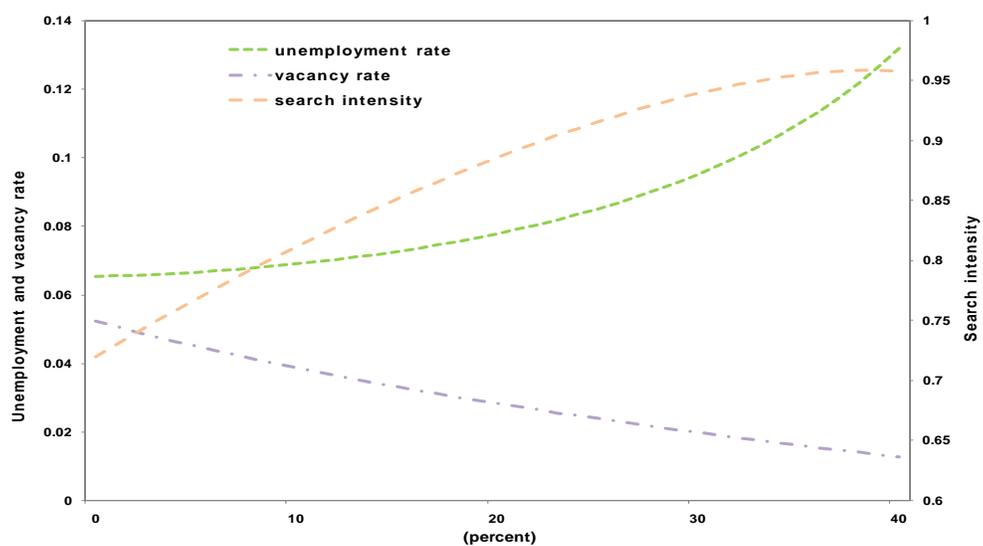

**Figure 3. Impact of search cost cuts on search and unemployment**

*Note:* Unemployment rate is number of unemployed as % of labour force. For units of consumption good, the price of the consumption good is normalised to one.

*Source:* Author's calculations.

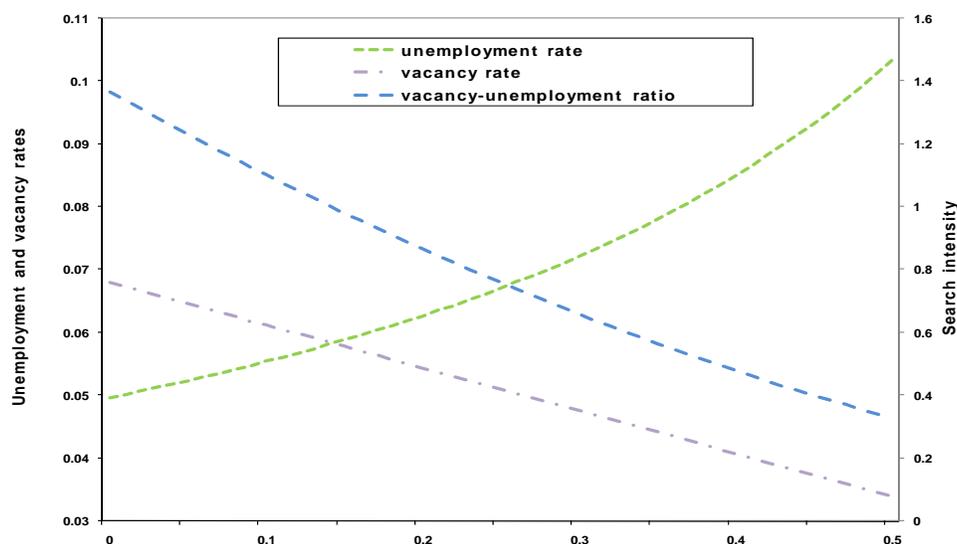

**Figure 4. Impact of minimum wage increase on search, unemployment and vacancies**

*Note:* Unemployment and vacancy rates are respectively the number of unemployed and vacancies as % of labour force. For units of consumption good, the price of the consumption good is normalised to one.

*Source:* Author's calculations.

**Figure 5. Impact of social security tax on vacancies and unemployment**

*Note:* Unemployment and vacancy rates are respectively the number of unemployed and vacancies as % of labour force. The vacancy/unemployment ratio is the vacancy rate divided by the unemployment rate.

*Source:* Author's calculations.

Figure 4 illustrates the impact of increases in minimum wages on the low-wage unemployed workers for whom these wages may constitute a binding constraint. While workers would increase their search/training effort because of a higher payoff from working, the positive impact could be more than offset by firms' posting fewer vacancies because of lower profits. Figure 5 illustrates the likely impact of cuts in social contribution tax paid by employers. The direct consequence would be a higher profitability of firms and hence more vacancies/lower unemployment rate, provided that the lost revenues are replaced by less distortionary taxes.

### 3.4. Policy lessons

The above simulation exercise helps us draw several policy conclusions:

- Linking increases in unemployment benefits to participation in job search or training programmes would improve workers' incentives to search for jobs or put effort into training, by reducing the value of being unemployed and improving their chances of finding a job.
- While lower minimum wages would somewhat hamper incentives of the low-wage unemployed to search for jobs or be retrained, firms would be more willing to hire. The unemployment rate could decline as long as the prevailing minimum wage level is binding.
- A lower tax wedge due to cuts in firms' social security contributions would raise firms' payoff from filled jobs, and hence their incentives to post vacancies. Search or training effort of workers would also increase, as their chances of finding jobs would improve. Both the unemployment level and duration would decline.

### 3.5. *The transition costs*

Although the results presented in the previous section focus on the longer term labour market outcomes, the above measures would also affect the speed of adjustment and the associated transition costs, and hence the political support for reforms. Generally, the speed of adjustment is faster when labour market flexibility is enhanced, underlying for example the importance of reducing the social security tax, especially on low income workers, as a way to ease the recovery and reduce medium term unemployment.

Mourougane and Vogel (2008), who examined the length of adjustments to selected structural reforms in the OECD countries, found that the impact of structural reforms takes several years. As reallocating resources (e.g., labour) is costly, the efficiency gains take time to materialize. Effective monetary policy and well functioning financial markets can reduce the adjustment speed and transition cost through, for example, facilitating the access of new firms to credit. According to the authors, the tax wedge on labour, unemployment replacement ratio, and product market regulations play a major role in explaining the evolution of structural unemployment in OECD countries during 1983–2003. Tax wedge and product market regulations also have the largest impact in the short run. The importance of easing employment protection is in accordance with results of Caballero *et al.* (2004), who found that in countries with strong law enforcement, increasing job security would reduce the annual speed of adjustment to shocks by a third, while subtracting 1% from productivity growth.

While our model illustrations focus on the flexibility aspects of labour market reforms, the experience of other countries from the crisis and other episodes shows that the importance establishing adequate social protection mechanisms that would also help the unemployed search for appropriate jobs or retrain cannot be overstated. Putting differently, too low level of protection may force the unemployed to accept jobs that are not ‘good’ matches and hence increase the job dissolution rate and transaction costs associated with the job matching process.

## 4. **Confronting the results with stylised facts from OECD countries**

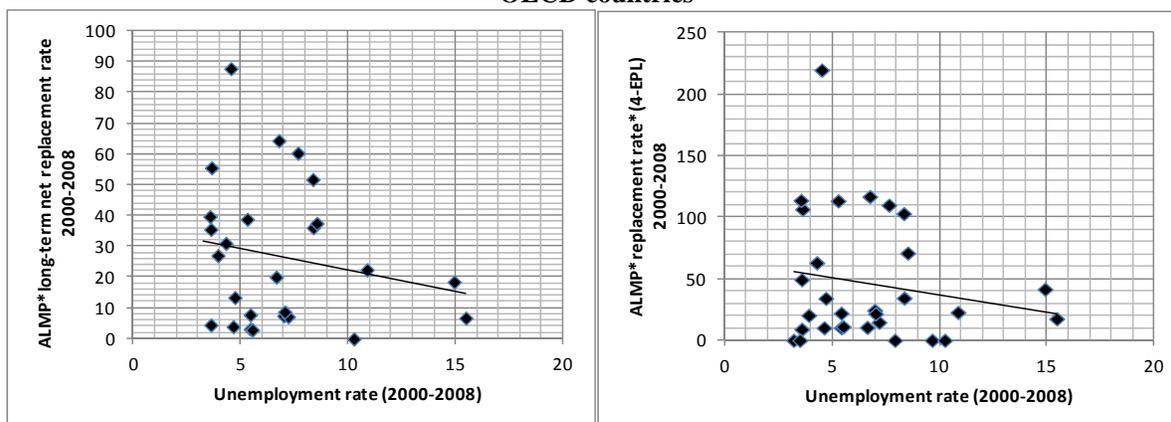

This section seeks to summarise available evidence from OECD countries regarding the impact of labour market reforms aimed to increase flexibility on the level of unemployment. Measures considered are: i.) ALMPs; ii.) the minimum wage; and iii.) the tax wedge.

### 4.1. *Active labour market policies and unemployment*

Over the medium term, increases in ALMPs would enhance workers’ employability and give a larger role to automatic stabilisers. Among various activation approaches, job search assistance or “work first” strategies tend to have a large positive impact and low cost. Long term labour market programmes alone, such as training, often have no or even a negative impact in the short term, but increase employment and earnings 2–3 years after the individuals completed them. Hence mixed strategies combining job search and selective training programme participation seem to be most effective (OECD, 2005a,b).

Well designed and targeted activation policies or training programmes can offset the disincentives due to generous unemployment benefits. For instance, the Danish Flexicurity model, which is based on low employment protection, high expenditures on active labour market policies and generous unemployment benefits conditional on the obligation to take on job offers seems to incentivise firms to create jobs and unemployed persons to take up new job offers. Figure 6 below shows that the combination of extensive ALMP with higher net replacement rates and lower employment protection legislation might go in tandem with lower unemployment rates in OECD countries.

**Figure 6. The combination of ALMP, EPL and generous contributions and unemployment rate in OECD countries**

Source: Authors' calculations using data obtained from the OECD

Note: Vertical axis of the left panel shows an indicator, which is the product of public expenditures on ALMPs as a share of GDP and the long-term net replacement rate of unemployed persons, both measures averages of the period 2000 to 2008. Vertical axis of the right panel is augmented by the effect of the inverted employment protection legislation indicator (EPL). EPL ranges from 1 (least restrictive) to 4 (most restrictive). Hence, a low EPL would increase the overall value of the product of the three sub-indicators, while a high EPL would lower it. The unemployment rate is the period average for 2000-08.

The experience of OECD countries suggests that Estonia could improve the effectiveness of its ALMPs at a given level of expenditures by linking increases in unemployment benefits to participation in ALMP programmes and monitoring performance of the employment offices. Increases of unemployment benefits and their duration should be conditional on work availability and active job search and/or participation in job creating or training programmes (OECD, 2006). To raise ALMP's effectiveness, efficiency of employment services could also increase. Regarding benefit conditionality, Estonia could introduce practices of some of the OECD members:

- Required frequency of reporting of search activities could be raised from monthly to every two weeks, as is done, for example, in Australia, the Czech Republic, United Kingdom, and the United States. Personal visits seem most effective (OECD, 2007).
- Increases in benefit entitlements should be conditional on participation in ALMPs programmes, such as job creation (entrepreneurship) or training. Similar links have been established in Australia (Mutual obligation strategy); the UK (New Deal strategy) and other European countries (Grubb, Singh and Tergeist, 2009).

#### 4.2. *Minimum wage, tax wedge and unemployment*

A prevailing view in the economic profession is that a high tax wedge could lead to an insufficient creation of firms and jobs, and constitutes a particularly strong impediment for SMEs. Panel A of Figure 7 shows that a higher tax wedge goes hand in hand with higher unemployment rates in OECD countries. In the case of Estonia, surveys conducted by the Estonian Research Institute indicate that high taxes on labour are the main reason for undeclared work (Leetmaa and Vork, 2007). Against this backdrop, one of the proposals of the employers' representatives is to shift the burden of taxation from employers towards workers, by splitting the contribution between these two parties (Employers' Manifesto for 2007 – 2011).

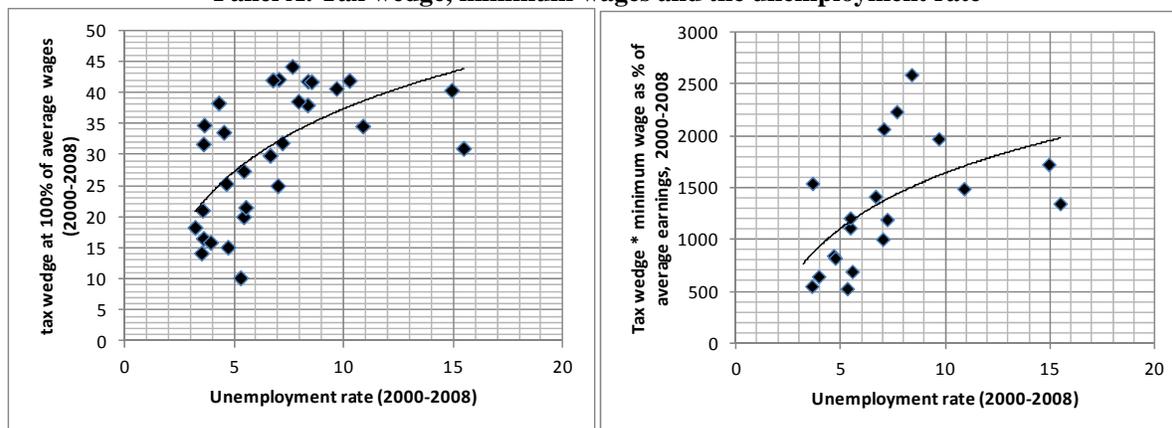

High tax wedges are particularly detrimental to employment in countries with high minimum wages, because the tax burden cannot be passed on to workers (Bassanini and Duval, 2006). In fact, data shown in Panel A of Figure 7 that a higher tax wedge is associated with a higher unemployment rate in OECD

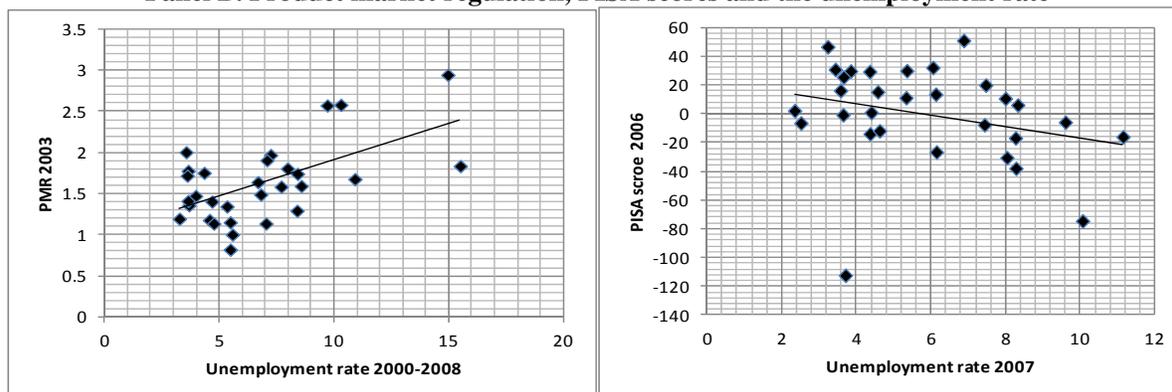

countries over the period 2000 to 2008. In addition, a positive correlation exists between the product of the tax wedge and the minimum wage (as a share of average earnings), on the one hand, and the unemployment rate, on the other, implying that a higher tax wedge coupled with a higher minimum wage is linked to a higher unemployment rate in OECD countries.

In the Estonian context this provides additional reasons (besides macroeconomic and inflationary considerations) why minimum wage increases should be kept in line with productivity growth and at a level which does not reduce employment options of low-productivity workers. Estonia could include an independent committee of outside experts in negotiations, also to bring the macroeconomic perspective, as was done, for example, in Ireland, the United Kingdom, and Australia. In addition, the employers' social security contribution should be reduced, especially given the high tax wedge on low-income workers, as was recently done, for example in the Czech Republic in the context of the economic crisis.

More general policies may also influence labour market outcomes. A business-friendly environment that promotes the creation of firms and allows for more flexibility in adjusting to shocks is likely to reduce the unemployment rate. Panel B of Figure 7 shows a positive correlation between product market regulations (PMR) and unemployment rate in OECD countries: a lower degree of regulation is associated with a lower unemployment rate. A better educated labour force is also essential to reduce frictions in matching job offers with job seekers. An increased ability to learn and think independently at the age of 15, captured by the PISA scores, tends to be associated with lower unemployment rates in OECD countries (Panel B of Figure 2). More broadly, and as shown in the above model, adult learning, in particular well targeted training programmes to close skill gaps in selected areas, can also help align workers' skills with demands of the labour market.

**Figure 7. Policies and the unemployment rate in OECD countries**  
**Panel A. Tax wedge, minimum wages and the unemployment rate**

**Panel B. Product market regulation, PISA scores and the unemployment rate**

Source: authors' calculations using data obtained from the OECD

Note: Vertical axis of the left panel of Panel A shows the tax wedge at 100% of average wages for 2000-08. The right panel of panel A shows an indicator which is calculated at the tax wedge multiplied by the minimum wage as a share of average earnings over the period 2000-08. Vertical axis of panel B depicts the 2003 vintage of product market regulation (PMR) and the 2006 PISA scores. The unemployment rate is the period average for 2000-08.

## Conclusions

Following years of steady decline during 2001-2007, the unemployment rate in Estonia increased dramatically from 4.1 percent in December 2007 to 19.8 percent in June 2010 after the country entered a severe recession in 2008. While the rate was already down to 13.3 percent in September 2011, it remains high, especially among the less educated segments of the population. In this paper we examined labour market institutions and policies that may help Estonia reach better longer term labour market outcomes become.

While the Estonian labour market had been already flexible in many ways, the Employment Protection Legislation adopted in 2009 removed some of the remaining rigidities that hampered hiring of new workers, especially first entrants to the job market. It also eased transition from less to more productive activities, which is consistent with Estonia's objective to become a knowledge-based economy. The Estonian labour markets would also benefit from reduction of high tax wedge on wages as well as from keeping increases of the minimum wage in line with changes in labour productivity.

Results of a simulated search-matching model suggest that Estonia could adopt several measures to increase flexibility of its labour market and thus ease the recovery and improve medium term outcomes. These measures include strengthening incentives of the unemployed workers to search for jobs or participate in training and job search programmes and incentives for firms to create job creation such as: (1) implementing fully the reduced lay-off notice periods and severance payments, as stipulated in the Employment Contract Act; (2) making increases in unemployment benefits conditional on active job search and retraining; and (3) reducing the tax wedge by cutting social security contributions of employers, especially on low-wage workers. The Estonian labour market would also benefit from improving employment incentives for low wage workers, such as reducing social security contributions of employers on low wage workers, as adopted, for example, in the Czech Republic as part of the anti-crisis package.

While not addressed in this paper, the experience of other countries shows that adequate social protection mechanisms would also improve longer term labour outcomes by allowing the unemployed to search for appropriate jobs or retrain for new jobs arising from structural changes in the economy. We leave this important topic for further research.

# **Labour Market Reforms in Portugal 2011-2015**

## **A PRELIMINARY ASSESSMENT**

## FOREWORD

This report, commissioned by the XIX Government of Portugal, provides an evaluation of the comprehensive labour market reforms undertaken in Portugal over the period 2011-2015. It describes reforms in the areas of employment protection legislation, unemployment benefits, activation, collective bargaining, minimum wages and working time. The report reviews the reforms in detail and assesses the available evidence on the impact they have had on the labour market.

Assessing the impact of these reforms on the labour market is not an easy task, not least because they were introduced in a relatively short period of time and together with other reforms outside the labour market. They also coincided with a second dip in GDP growth and a gradual recovery. Disentangling the effects of the labour market reforms from these contemporaneous events is not straightforward. In addition, many of the effects of the reforms will become fully evident only in the medium- to long-run.

The present report should therefore be seen as a preliminary assessment of those reforms. That being said, it is possible, even at this stage, to make some observations about key policy priorities for the future – and the report offers some recommendations to that effect. While further reforms of labour market institutions, policies and practices will be required, achieving higher levels of employment and greater inclusiveness in Portugal will also depend on factors that lie outside the realm of labour market policy – not least on a return to higher and more sustainable levels of growth.

The report was prepared by Stijn Broecke and Marieke Vandeweyer (both from the Employment Analysis and Policy Division – EAP – in the OECD Directorate for Employment, Labour and Social Affairs – ELS). Sofia Pessoa e Costa (Queen Mary, University of London) worked as a consultant on the project, and Andrea Bassanini (ELS/EAP) provided technical and expert advice throughout.

The report benefited from useful comments provided by Stefano Scarpetta (Director for Employment, Labour and Social Affairs, ELS), Mark Pearson (Deputy Director, ELS) and Mark Keese (Head of Division, ELS/EAP). Further comments were provided by Jens Arnold and Sonia Araújo (from the Economics Department), Rodrigo Fernandez and Sean Gibson (from the Social Policy Division in ELS), and Andrea Garnero and David Grubb (ELS/EAP).

Special thanks go to Ricardo Alves (Director of Strategy and Studies at the Ministry of Economy), Mariana Trigo Pereira (Chief Economist at the Ministry of Labour, Solidarity and Social Security), Antonieta Ministro (Head of Department of the Cabinet of Strategy and Planning, Ministry of Labour, Solidarity and Social Security), and Maria Manuela Oliveira Fernandes and Sandrine Miranda (both from the Portuguese Delegation to the OECD) for their considerable contribution to ensuring a successful completion of his project.

The OECD Secretariat would also like to thank: the National Institute of Statistics for providing access to the Portuguese Labour Force Survey; the Directorate of Statistics Services at the Ministry of Economy for preparing and sharing an extract of social security data; and the Public Employment Service (*Instituto do Emprego e Formação Profissional*) for access to their administrative data.

Finally, the OECD Secretariat is grateful to: all the Portuguese officials who provided comments on the report (and, in particular, Carlos Domingues for sharing his knowledge on Portugal's collective

## EXECUTIVE SUMMARY

Portugal was badly hit by the global financial crisis and suffered unprecedented job losses. Total employment fell by 767 000 (-15%) between mid-2008 and the beginning of 2013 and, at its peak, the unemployment rate stood at 17.3% (up from 8.6% at the beginning of 2008). The crisis added to Portugal's labour market problems. Unemployment had been rising even before the crisis (from 5.1% in 2000), its labour market was highly segmented, and the long-term unemployment rate was among the highest observed in the OECD. In order to deal with these deep-rooted structural weaknesses, a comprehensive set of labour market reforms was implemented over the period 2011 to 2015. More specifically:

- Portugal significantly reduced severance pay and eased the definition of fair dismissals as part of one of the most substantial reforms of *employment protection legislation* (EPL) among OECD countries in recent years, bringing the strictness of the country's regulations closer in line to the EU average. There is some early indication that these reforms have incentivised on-the-job search (a lead indicator of job-to-job flows) as well as hiring. While the reforms have narrowed the regulatory gap between permanent and temporary contracts (and appear to have encouraged hiring on permanent contracts), this gap remains important and continues to contribute to labour market duality.
- Against a backdrop of rising unemployment and EPL reforms which made it less costly for employers to dismiss workers, Portugal widened the safety net provided by *unemployment benefits*. At the same time, the maximum duration of these benefits was reduced in an attempt to reduce long-term unemployment, although the full impact of this reform will take time to materialise because the new rule only applies from the second unemployment spell after the reform. These changes have brought the Portuguese unemployment benefit system more in line with standard practice across the OECD, but coverage remains relatively low and maximum benefit duration high.
- To help the unemployed back into work Portugal strengthened its *activation framework*. While eligibility criteria for unemployment benefits have always been strict on paper, recent measures tightened the way these criteria are implemented in practice – and there is some evidence that this has increased exits from unemployment. Portugal has also significantly increased its offer of short-term training programmes and hiring subsidies for the unemployed, set up a Youth Guarantee, and put in place a comprehensive strategy to modernise the Public Employment Service (although some measures included in this strategy have yet to be implemented).
- Reforms of the *collective bargaining* system aimed to promote a closer alignment between wages and productivity at the level of the firm by: introducing representativeness criteria for the extension of collective agreements; allowing firm-level agreements to be negotiated by works councils in firms with at least 150 employees (500 prior to the reform); and introducing a possibility for employers to temporarily suspend a collective agreement during times of crisis. While some of the initial reforms and measures (which have since been reversed) may have contributed to a reduction in collective bargaining coverage, the decline in the number of sector agreements was also crisis-induced and is, in fact, part of a longer-term trend which started in the mid-1990s. More generally, it is unlikely that the recent reforms will have much impact given that the current representativeness criteria for extensions are easily fulfilled; worker representation at the firm-level is weak; and the conditions for opting out of sector agreements remain vague and therefore open to conflict.

- In face of the crisis, the Portuguese Government also attempted to achieve *wage moderation* by freezing the national minimum wage between 2011 and 2014; reducing compensation for overtime work; and cutting public sector pay. Although low in absolute terms, the minimum wage in Portugal remains quite high compared with other OECD countries when expressed as a proportion of median wages. Moreover, employers also face a high rate of taxes and social security contributions on minimum wage workers (23.75% versus 19% across the OECD on average). Both of these factors raise some concern about a possible negative impact of future increases in the minimum wage on the employment of low-wage workers.
- Finally, as in a number of other European countries, firms facing economic difficulties were granted additional flexibility towards the middle of 2012 to adjust *working time* instead of employment. This is a welcome development given that the adjustment in labour input to the crisis in Portugal had primarily occurred through job destruction, in contrast to what had happened in some other OECD countries. That being said, the use of flexible working-time practices is likely to remain low in Portugal as long as there is a high share of temporary employment, which makes it easier for firms to adjust labour inputs along the extensive employment margin.

The Portuguese labour market reforms were a move in the right direction. Since economic growth turned positive again in early 2013, Portugal has experienced significant improvements in both employment and unemployment rates – greater, in fact, than what one would have expected given the pace of the recovery. However, despite the progress made, many challenges remain. Unemployment remains high (particularly among youth) and this situation has fuelled an increase in both poverty and long-term unemployment (although there are signs of improvement in the latter). The labour market remains highly segmented and, in the context of very low inflation, the presence of downward nominal wage rigidity is likely to remain a barrier to the competitiveness of the Portuguese economy – unless productivity growth is strengthened.

In view of these remaining challenges in the labour market, tackling segmentation should be a key priority for the Portuguese Government, and this can be partly achieved by further reducing the regulatory gap between permanent and temporary contracts. At the same time, the safety net for those out of work needs to be strengthened by a further widening in the coverage of unemployment benefits, but the maximum duration of these benefits could be reduced further in a bid to tackle long-term unemployment. But, to be effective, employment programmes to support the reintegration of jobseekers into employment should also be strengthened.

Competitiveness needs to be improved by aligning collective bargaining processes more closely with firm performance. In particular, the potential for negative effects of administrative extensions of collective agreements on non-signatory firms should be minimised, and the procedures for firms facing economic hardship to opt out of such agreements should be clarified. Finally, further increases in the minimum wage might help address in-work poverty but, to minimise any potential job losses, reductions in employers' social security contributions on minimum-wage workers should be considered.

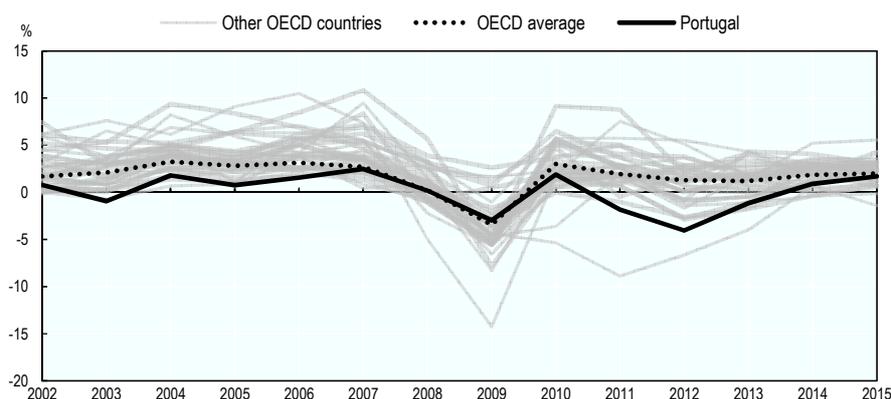

More generally, further improvements to Portugal's job market performance will require tackling other economic challenges. These include: the need to return to higher and more sustainable levels of growth; further reforms of product market regulations; better access to credit for firms; a reduction in employers' non-wage labour costs; and additional investments in skills.

## ASSESSMENT AND RECOMMENDATIONS

The global economic and financial crisis triggered a severe recession in Portugal, leading to a significant increase in unemployment. Between mid-2008 and the beginning of 2013, an estimated 767 000 individuals (or one in seven workers) lost their job. At its peak (Q1 of 2013), the unemployment rate in Portugal stood at a record high of 17.3% – more than twice the OECD unemployment rate at that time.

However, economic and labour market performance was poor in Portugal even before the crisis hit, and the recession painfully exposed pre-existing weaknesses and imbalances. Over the period 2002 to 2008, annual real GDP growth in Portugal was consistently among the lowest in the OECD area: less than 1%, compared to 2.3% across the OECD on average (Figure 1) and the unemployment rate increased from 5.0% in 2002 to 7.6% in 2008. Since the mid-1990s, unit labour costs had been rising faster than in core European countries, eroding competitiveness (OECD, 2010a), and external and public deficits were persistently high (Portugal, 2015).

Figure 1. Annual real GDP growth rate, Portugal and OECD, 2002-2015

Source: OECD Economic Outlook No. 98, November 2015.

When the crisis hit, the public deficit ballooned as high public spending (partly driven by countercyclical measures) coincided with a fall in public revenue. Investors and creditors became nervous about Portugal's ability to rein in its budget deficit and debt, and access to international financial markets became increasingly difficult. As a result, Portugal faced growing difficulties in meeting international payment obligations and, in April 2011, ended up requesting financial assistance from the European Union, the European Central Bank and the IMF (the "Troika") to solve its sovereign debt crisis. A financial assistance programme, amounting to EUR 78 billion over a period of three years, was agreed in May 2011. The programme was made conditional on a set of fiscal consolidation measures and structural reforms, which were described in detail in the Memorandum of Understanding signed between Portugal and the three institutions.<sup>1</sup> These reforms focused on the following key objectives: i) budgetary

1. Many of the reform proposals included in the MoU had already been included in a tripartite agreement that preceded Portugal's request for assistance (*Acordo Tripartido para a Competitividade e Emprego* signed on 22 March 2011- although the MoU went beyond the measures included in this document) and had been the subject of an earlier white paper (*Livro Branco das Relações Laborais*). In addition, Portugal had already been implementing important labour market reforms since 2003 (Távora and González, 2015).

consolidation; ii) financial sector stabilisation; and iii) structural reforms to boost growth and competitiveness.

Among the structural reforms to boost growth and competitiveness in Portugal, the Troika gave high priority to reforms of labour market institutions and policies, including: unemployment benefits; employment protection legislation; working time arrangements; wage-setting mechanisms; and active labour market programmes. Among the key challenges to be addressed were:

- *A highly segmented labour market.* Portugal had very rigid employment protection legislation on open-ended contracts, making it an outlier on the OECD's EPL indicator. The difficulty of making workforce adjustments through permanent contracts, a high degree of (nominal) wage rigidity, and the relative ease of use of temporary contracts, led to a share of temporary employment which was one of the highest in the OECD area (affecting one in five Portuguese workers in dependent employment, and young workers in particular).
- *One of the highest long-term unemployment rates in the OECD.* Even prior to the crisis, nearly one in two unemployed individuals in Portugal had been out of a job for more than a year (compared to just one in eight in OECD countries on average). This was partly driven by deep structural changes resulting from globalisation and technological change, which have led to a large number of displaced workers with poor skills facing significant barriers in finding new jobs. However, Portugal's generous unemployment benefit system (for those eligible) and a weak activation framework were also partly to blame. At the same time, the coverage of the unemployment benefit system was relatively low.
- *A high level of (nominal) downward wage rigidity.* Portugal's collective bargaining system and legal restrictions around nominal wage cuts resulted in significant downward wage rigidities. Consequently, during a period of low inflation (like the recent crisis), employers have very little leeway to adjust real wages, which leaves employment (and temporary employment in particular) as the main margin of adjustment. This partly explains the surge in unemployment Portugal experienced during the crisis (Carneiro, Portugal and Varejão, 2014).

In January 2012, the government signed the “Growth, Competitiveness and Employment Pact” (*Compromisso para o Crescimento, Competitividade e Emprego*) with the social partners.<sup>2</sup> The set of measures outlined in the pact corresponded closely to the reforms that were eventually implemented, and also gave them their legitimacy. The reforms (discussed in Chapter 1 and in more detail in Annex A) were implemented over several years (see timeline in Annex B), and with some difficulties. Some reforms were strongly opposed by the social partners (and therefore never implemented).<sup>3</sup> Others were implemented, but subsequently revoked by the Constitutional Court since they were considered unconstitutional.

Despite the long and tortuous path, a lot has been achieved by Portugal over this period: within the context of the Memorandum of Understanding alone (but including reforms in areas outside the labour market), over 450 measures were implemented – equivalent to around three measures per week (Government of Portugal, 2014). As the timeline in Annex B testifies, labour market reforms over the period were implemented almost on a monthly basis. While additional reforms are undoubtedly necessary, it is important to also take stock of what has been achieved to date, and assess how well the measures implemented have succeeded in meeting their intended objectives. In this spirit, the government committed

2. Although one of the union federations (the General Confederation of Portuguese Workers – *Confederação Geral dos Trabalhadores Portugueses* – CGTP) refused to sign it.

3. These include the proposal to increase the daily maximum working time by half an hour, as well as the proposal to increase the compulsory social security contributions of workers (public and private sector) from 11% to 18%, and to decrease employers' contributions from 23.75% to 18%.

to monitoring carefully its labour market reforms to assess if they are having the intended impact and fine-tune accordingly (Government of Portugal, 2014).

The present report, commissioned by the Government of Portugal, is one contribution to this process of monitoring and evaluation. It focuses primarily on the labour market reforms carried out during the period 2011 through to the first semester of 2015. Chapter 1 describes these reforms in some detail, the rationale behind them, their expected outcomes, as well as the available evidence on the actual impact they have had on the labour market. Chapter 2 then assesses the performance of the Portuguese labour market over the past few years, and the final chapter discusses areas where further reforms/fine-tuning may be necessary.

The main findings and recommendations of the report are as follows:

### **Employment protection legislation**

- Prior to the reforms, Portugal was a significant outlier among OECD countries in terms of the strictness of its employment protection legislation (EPL) for individual workers on permanent contracts, driven primarily by: demanding procedural requirements for employers initiating a dismissal process; high severance payments; and the strong likelihood of reinstatement in cases of unfair dismissal. At the same time, a large regulatory gap existed between permanent and temporary contracts, contributing to the high degree of segmentation in the labour market.
- As part of the reforms, Portugal significantly reduced the amount of entitlements to severance pay for new hires (while largely preserving the accumulated rights of existing workers). The reduction was particularly large for permanent contracts, and, for the same job tenure, severance pay for dismissals on permanent contracts is now lower than it is on temporary contracts. Portugal also attempted to ease the definition of fair dismissal through the introduction of a new reason for dismissal (inadaptability without change to the nature of the job) and the introduction of more objective (performance-related) criteria for dismissing workers in the case of extinction of a work position. However, these latter reforms were only a mixed success as important aspects of them were ruled unconstitutional.
- The Portuguese EPL reforms rank among the most substantial of those implemented by OECD countries in recent years. Preliminary analysis carried out for the purpose of this report suggests that the reductions in severance pay may already have had a positive impact on on-the-job search (a lead indicator of job-to-job flows), as well as on hiring and the share of hiring that is on permanent contracts. At the same time, the preservation of accumulated severance pay entitlements appears to have protected existing workers from an increased risk of dismissal as a result of the reforms. In the long run, the cuts in severance pay are expected to result in significant gains in both productivity and growth. It will be important to build on the positive impact of these reforms on Portugal's labour market performance, and a number of areas remain where these reforms could be bolstered.
- While Portugal's reforms have moved the stringency of its EPL closer to the OECD average, the regulatory gap between permanent and temporary contracts remains significant, and this continues to contribute to labour market segmentation.
- Reducing further the disincentives to hire workers on a permanent contract could be achieved by clarifying the conditions under which employers can dismiss individual workers for economic reasons – similar to the reforms that have recently been undertaken in both France and Spain.<sup>4</sup> This is likely to require a change to the Constitution (Article 53 which prohibits dismissals without “just cause”, but without defining what the latter means) and may be difficult to achieve in practice. Even in the absence of a constitutional change, however, further reductions in employment

---

4. OECD (2013b, 2013c).

protection for workers on permanent contracts can and should be achieved by: reducing the compensation following unfair dismissal and reducing the possibilities for reinstatement.

- Another option to reduce labour market duality would be to make hiring on temporary contracts relatively more expensive, for instance by charging higher social security contributions (as was done in Slovenia, France and Italy). However, while this would help reduce segmentation, there is a risk that higher labour costs would reduce employment opportunities, particularly for the marginal worker. This may be particularly problematic in sectors with a large share of seasonal workers (like tourism and agriculture).
- The reforms also introduced changes to the way severance payments are to be made. Two dismissal funds collecting regular contributions from employers were set up which are intended to: i) cover part of the severance pay in case a worker is dismissed; and ii) guarantee a minimum amount of severance pay for the employee in case the employer cannot pay. While this new system reduces the up-front cost of dismissal to the employer and offers some insurance to the employee, it does not solve the problem that high accumulated severance pay rights act as a disincentive to mobility for the workers concerned.
- Another aspect of labour market segmentation in Portugal is the high incidence of dependent (or “false”) self-employment, which puts many workers in a very vulnerable position *vis-à-vis* their employer. While Portuguese labour law already defined the conditions under which an employment contract would be presumed, the recent reforms gave labour inspectors (*Autoridade para as Condições do Trabalho* – ACT) additional tools for enforcing the law and regularising contracts in the case of non-compliance. At the same time, however, there are indications that there is a lack of resources for effective implementation of these new provisions.

#### **OECD recommendations: Employment protection legislation**

1. Clarify the conditions under which employers can dismiss individual workers on permanent contracts for economic reasons, following the recent examples of both France and Spain.
2. The above recommendation may be difficult to implement because it requires an amendment of Article 53 of the Constitution. Nevertheless, even without such a change, further reductions in employment protection legislation for workers on permanent contracts can still be achieved by:
  - Reducing compensation following unfair dismissal; and
  - Limiting the possibility of reinstatement in the case of unfair dismissal. A reduction in the risk of litigation and reinstatement for employers could be achieved by making the receipt of (ordinary) severance pay conditional on individuals renouncing their right to litigation – similar to current practice in Germany.
3. Labour market duality could also be reduced by raising the relative cost of hiring on temporary contracts (e.g. by charging higher social security contributions) – however this may come at the expense of employment, which would affect marginal workers in particular. Therefore, one may wish to waive these higher social security contributions when firms hire marginal workers (e.g. low-skilled, youth and the long-term unemployed).
4. Disincentives to worker mobility could be reduced by making severance pay funds portable from one employer to another (as in Austria) – although the costs of moving to such a system should be carefully weighed against the benefits.
5. Strengthen the capacity of the labour inspectorate (ACT) to further clamp down on “false” self-employment (i.e. self-employed workers who are economically dependent on a single employer).

## Unemployment benefits

- Prior to the recent reforms, Portugal had a relatively generous unemployment benefit system for those eligible compared to other OECD countries, which is likely to have contributed to a high rate of long-term unemployment. To address this issue, Portugal lowered the cap on the maximum benefit amount and introduced a declining replacement rate to incentivise a more rapid return to work. In addition, the maximum duration of unemployment benefits was shortened – although this would only apply from the second unemployment spell onwards, so that an element of protection was kept in place during the recent episode of high unemployment. This also means that the impact of this latter reform on long-term unemployment will take time to materialise and that, unfortunately, its impact cannot yet be assessed. At the same time, preliminary evidence on the impact of the reductions in benefit levels suggests that they may have increased exits from unemployment – although the estimates are statistically insignificant. These reforms have moved Portugal closer to the OECD average in terms of the generosity of unemployment benefits and, to the extent that international evidence and past experience in Portugal provide useful insights, they should eventually help shorten unemployment spells and reduce the level of long-term unemployment. That said, the average maximum duration of unemployment benefits remains relatively high in Portugal compared with the OECD average.
- With unemployment soaring and EPL reform making it easier and less costly for employers to dismiss workers, there was also a need to widen the safety net provided by unemployment benefits. By international standards, the coverage rate of unemployment benefits (measured as the ratio of beneficiaries to the number of LFS unemployed) is relatively low in Portugal. Therefore, Portugal relaxed the contribution requirements for gaining access to unemployment insurance. The evidence suggests that, despite a significant increase in unemployment between 2011 and 2013 (and, in particular, an increase in long-term unemployment and the number of individuals with shorter contribution histories), the coverage rate of unemployment benefits held up well – but it remains at a low level. Of particular concern is the coverage of youth and others with short or incomplete contribution records (including those on non-regular employment contracts). In addition, the reduction in generosity of the *Rendimento Social de Inserção* (RSI) – a means-tested benefit of last resort – resulted in an important decline in the number of beneficiaries, causing significant hardship among the poor.

### OECD recommendations: Unemployment benefits and social assistance

6. Provide greater protection for the unemployed by widening further the coverage of unemployment benefits. One option would be to raise the means test threshold for unemployment assistance and uprate it annually in line with inflation.
7. At the same time, further reduce the maximum duration of unemployment benefits to strengthen incentives for job search and tackle the high incidence of long-term unemployment – particularly for older workers. This should include restricting the possibility of extending unemployment assistance until the age of retirement to only those older people who remain unemployed despite taking active steps to find work. However, these reforms should be combined with measures to reinforce employment programmes to support the reintegration of jobseekers into employment (see below).

## Activation

- Moving individuals from unemployment into jobs also requires an effective activation framework to connect people with jobs. This includes the incentives to find work contained in the unemployment benefit system, but also other determinants of motivation, measures to promote employability, as well as policies to increase the number of opportunities available to jobseekers.

- Over the period 2011-2015, Portugal took several steps to strengthen its activation framework. While eligibility criteria for unemployment benefits (i.e. the criteria determining ongoing eligibility which require recipients to actively look for work, take up suitable job offers or take part in active labour market programmes) have always been strict on paper, recent measures have tightened the way these criteria are implemented in practice, with some proven success in terms of exits from unemployment.
- Portugal has also significantly ramped up its offer of short-term training and hiring subsidies for the unemployed, which international evidence suggests can be particularly effective for the long-term unemployed at times of crisis. However, the coverage of these programmes has broadened over time and there may now be a need to re-focus some of these measures (including those covered under the Youth Guarantee) on those who need them most (i.e. disadvantaged youth and the long-term unemployed). In addition, there have been numerous and frequent changes in these programmes in recent years, which may make it difficult for jobseekers and employers to know exactly what help is available to them. While new analysis contained in this report suggests that hiring subsidies and subsidised internships may be particularly helpful to assist the unemployed back into work, there is generally very little evaluation of the effectiveness of active labour market programmes in Portugal.
- There has also been a concern that some of the active labour market programmes, by encouraging hiring on temporary contracts, have not led to sustainable job creation. One option forward would be to build stronger incentives to hire on permanent contracts into active labour market programmes. For example, some OECD countries train the unemployed to fill existing vacancies and, in return, expect the employer to hire the individual on a permanent contract (e.g. Individual Job Training in Flanders, Belgium and Work and Income Support in New Zealand). The risk, however, is that this would reduce the overall take-up of such programmes. In addition, many of Portugal's existing active labour market programmes already offer larger subsidies to employers if they hire on permanent contracts – but there is no evidence as to whether these measures are actually effective or not.
- Finally, a comprehensive strategy has been defined to strengthen the Public Employment Service, which is a critical driver of the success of any activation programme. However, not all measures included in this strategy have yet been implemented and, going forward, it will be essential that they are.

#### OECD recommendations: Activation

8. Ensure that more costly active labour market programmes (ALMPs) are more closely targeted on those who need them most (i.e. disadvantaged youth and the long-term unemployed) and that programmes are well-tailored to the specific needs of jobseekers.
9. Consider building stronger incentives to hire on permanent contracts into active labour market programmes, but ensure that take-up by employers is not reduced unduly as a result and evaluate existing measures that incentivise hiring on permanent contracts.
10. Aim for more stability in the ALMP measures on offer to ensure jobseekers and firms have a better understanding of what help is available to them.
11. Devote more resources to the careful monitoring and evaluation of ALMPs. In particular, all new programmes should be trialed on a random, pilot basis.
12. Fully implement the measures outlined in the programme to modernise the Public Employment Service (*Programa de Relançamento do Serviço Público de Emprego*).

## Collective bargaining

- The issue of representativeness in Portugal's *collective bargaining* system remained unresolved despite important pre-crisis reforms. In particular, the combination of low coverage rates of both employer organisations and trade unions, on the one hand, and the practice of quasi-automatic extensions of collective agreements, on the other, led to the imposition of a large number of sector/occupation wage floors which did not necessarily represent the economic realities of non-signatory firms (and even less so the views of potential start-ups and the unemployed more generally). Moreover, firms are legally prohibited from reducing base wages (unless this is permitted by collective agreement) and rules around the validity of collective bargaining agreements meant that, in some cases, it was extremely difficult for employers to re-negotiate an agreement with unions. The consequence was a high level of downward nominal wage rigidity in the labour market. This can be particularly harmful at times of crisis with low inflation: if firms cannot adapt to worsening economic conditions by lowering (real) wages, the only other adjustment channel left for firms is to reduce employment (short of shutting down altogether). To make matters worse, when collective agreements were extended, the corresponding wage clauses often applied retrospectively, forcing employers affected to pay the resulting wage arrears. This tended to exacerbate the potential negative effects of administrative extensions on competitiveness and employment.
- A significant number of reforms were implemented during the crisis, all aimed at making the collective bargaining system more representative, decentralised and dynamic. Extensions of collective agreements were temporarily frozen in May 2011, and, from November 2012 onwards, they were only granted if the collective agreement met certain criteria in terms of the representativeness of the employers that signed up to it. These measures helped achieve some wage moderation during the crisis (and therefore saved jobs) – but the issue of representativeness has not yet been fully resolved. In particular, while the first condition introduced (requiring signatory employers to represent 50% of workers in the relevant sector/occupation/geographical area) was restrictive, a second, alternative condition added later (which also allows extension when 30% of signatory firms are small or medium enterprises) is very easy to fulfil given that 99.7% of firms in Portugal are SMEs.
- As part of the package of reforms, Portugal also allowed firm-level agreements to be negotiated by works councils in firms with at least 150 employees (previously this threshold was set at 500 employees) – but the lack of worker representation in smaller firms raises questions about how much difference this will make in practice. Portugal also took steps to encourage more frequent and swifter re-negotiations of collective agreements by placing additional constraints on the time for which they remain valid. Finally, a possibility was introduced for employers to temporarily suspend a collective agreement (or certain terms contained in it) at times of crisis. While (for obvious reasons) this can only occur upon agreement with the relevant unions, it is also likely to reduce the effectiveness of the measure unless: i) the conditions under which firms may opt out are further clarified (as was done in Spain); and ii) clear and swift procedures for resolving inevitable conflicts are established.
- The crisis period and the implementation of a large number of reform and austerity measures have put significant strain on the relationships between the social partners, and trust in social partners in Portugal is lower than in the OECD on average. Given the growing evidence that trust between social partners may be almost as important a determinant of collective bargaining outcomes as the collective bargaining institutions themselves, it is of critical importance that this trust be strengthened.

### OECD recommendations: Collective bargaining

13. Limit the negative consequences of administrative extensions of collective agreements by:
  - Making the representativeness criteria that regulate the extension of collective agreements more challenging (which would encourage employers to organise), while keeping them realistic (i.e. not impossible to meet).
  - Granting administrative extensions only if they are in the “public interest”, i.e. if they meet clearly defined criteria by the government which are announced well in advance and known by the social partners before they enter into negotiations. In other words, such public interest conditions would set the parameters within which collective bargaining would be expected to take place.
  - Alternatively, making the extension of collective agreements conditional on the inclusion of opening clauses which clearly specify the issues (including wages and working conditions) that can be delegated to the individual firm, and under what conditions.
  - Setting up an independent body responsible for deciding (or advising the government on) whether extensions should be granted – similar to those currently operating in Finland and Germany. This body could consist of representatives from unions, employers, as well as independent experts.
14. Make it easier for firms to opt out of collective agreements at times of crisis by:
  - Clarifying the conditions under which firms can opt out due to “inability to pay” or hardship. In Spain, for example, sectoral agreements have to include objective conditions (such as a fall in sales or productivity over a specified period of time) that specify when firms may opt out of what was agreed.
  - Introducing a swift arbitration process in case of disagreement between employers and worker representatives. Again, this could be modelled on the system in Spain where, following disagreement, employers can unilaterally refer the issue to arbitration with no right for either party to appeal against the decision.
15. Making it easier for firms to opt out should go hand in hand with measures to strengthen worker representation at the firm-level, for example by making works councils compulsory for firms of a certain size (like in France) or providing financial incentives for firm-level bargaining (Italy).
16. Enshrine in legislation the current practice whereby the retroactive effects of collective bargaining agreements which have been extended are limited to the first day of the month in which the extension occurs.
17. Build more trust between the social partners. While building trust is a complex process, it can be partly achieved by implementing some of the above recommendations, including: making unions and employer organisations more inclusive; promoting worker representation at the firm level; introducing objective criteria for both extensions and opt-outs; and encouraging regular negotiations (e.g. by reducing the maximum length of time for which agreements can remain valid).

## Wages

- Additional wage moderation was achieved by freezing the national minimum wage between 2011 and 2014; significantly reducing pay (and other compensation) for overtime work; and cutting public sector wages. The freezing of the minimum wage led to a slow erosion of its real value over the period 2011-2014 and hurt low-wage workers. OECD estimates for 2013 show that, in comparison with other OECD countries, minimum-wage workers in Portugal had to work a high number of hours to earn enough to move above the relative poverty line (50% of median income). At the same time, however, minimum wages are closer to the median wage in Portugal than in most other OECD countries. In addition, the rate of employer taxes and social security contributions for minimum-wage workers is higher than in most other OECD countries. Both these factors raise concerns about the possible dis-employment effects among unskilled workers

of the intended increase of the minimum wage to EUR 600 by 2019. While employers currently benefit from some reduction in social security contributions on minimum-wage workers, these are available for existing employees only.

#### OECD recommendations: Minimum wage

18. Reduce employer social security contributions on all minimum-wage workers, including new hires, to soften the impact of planned increases in the minimum wage on labour demand.
19. Set up an independent commission comprised of experts and representatives of the social partners to provide the government with impartial information and advice on future changes to the minimum wage, carefully considering current and future labour market conditions.

### Working time

- Firms in Portugal were given additional flexibility to respond to changes in demand by adjusting working time instead of employment. This is a welcome development, given that: i) in contrast to what happened in some other OECD countries, the adjustment in labour input to the crisis in Portugal occurred primarily through job destruction; and ii) there is evidence that short-time work compensation schemes and working time accounts have helped preserve jobs in a number of OECD countries during the crisis (OECD, 2010b). More specifically, the reforms reduced the procedural requirements and time needed to implement short-time work arrangements, and individual working time accounts were introduced alongside the collective working time accounts already in place. Portugal also improved the design of short-time work compensation schemes to reduce their deadweight loss.
- These changes have increased the use of flexible time practices in Portugal. However, given that the reforms were introduced relatively late during the crisis (mid-2012), they are unlikely to have done much to prevent job losses during the recession. In addition, their use remains relatively low in comparison with other countries, and this is likely to remain so as long as there is a high share of temporary employment which makes it easier for firms to adjust labour inputs along the employment margin. Finally, the risk that short-time compensation schemes preserve inefficient job matches and prevent the reallocation of labour to more productive uses increases if they are not phased out as the recovery sets in.

#### OECD recommendations: Working time

20. Phase out (or reduce the generosity of) short-time work compensation schemes as the recovery takes hold to prevent such schemes from becoming an obstacle to the recovery.

### The road ahead

While the reforms outlined above were a step in the right direction in terms of building a more resilient and inclusive labour market and appear to have had the intended effect, assessing their joint impact on the labour market is much more difficult because of the large number of reforms that were undertaken (including many outside the labour market) over a relatively long period of time. In addition, little time has elapsed since the reforms were implemented and, in many cases, results will only become visible in the medium- to long-run. At the same time, the reforms coincided with a second dip in GDP growth and a gradual recovery. Disentangling the effects of the reforms from those of the economic cycle is notoriously difficult. That being said, the report finds that the fall in unemployment since Portugal started recovering from the recession

(Figure 2, Panel A) is much larger than one would have expected based on the past relationship between economic growth and unemployment (see Chapter 2 for more detail). While this cannot be interpreted as causal evidence, the finding is nevertheless consistent with the impact that would be expected from the reform package as well as the demonstrated effects that some individual measures have had so far on exits from unemployment, on-the-job search and hiring, amongst others.

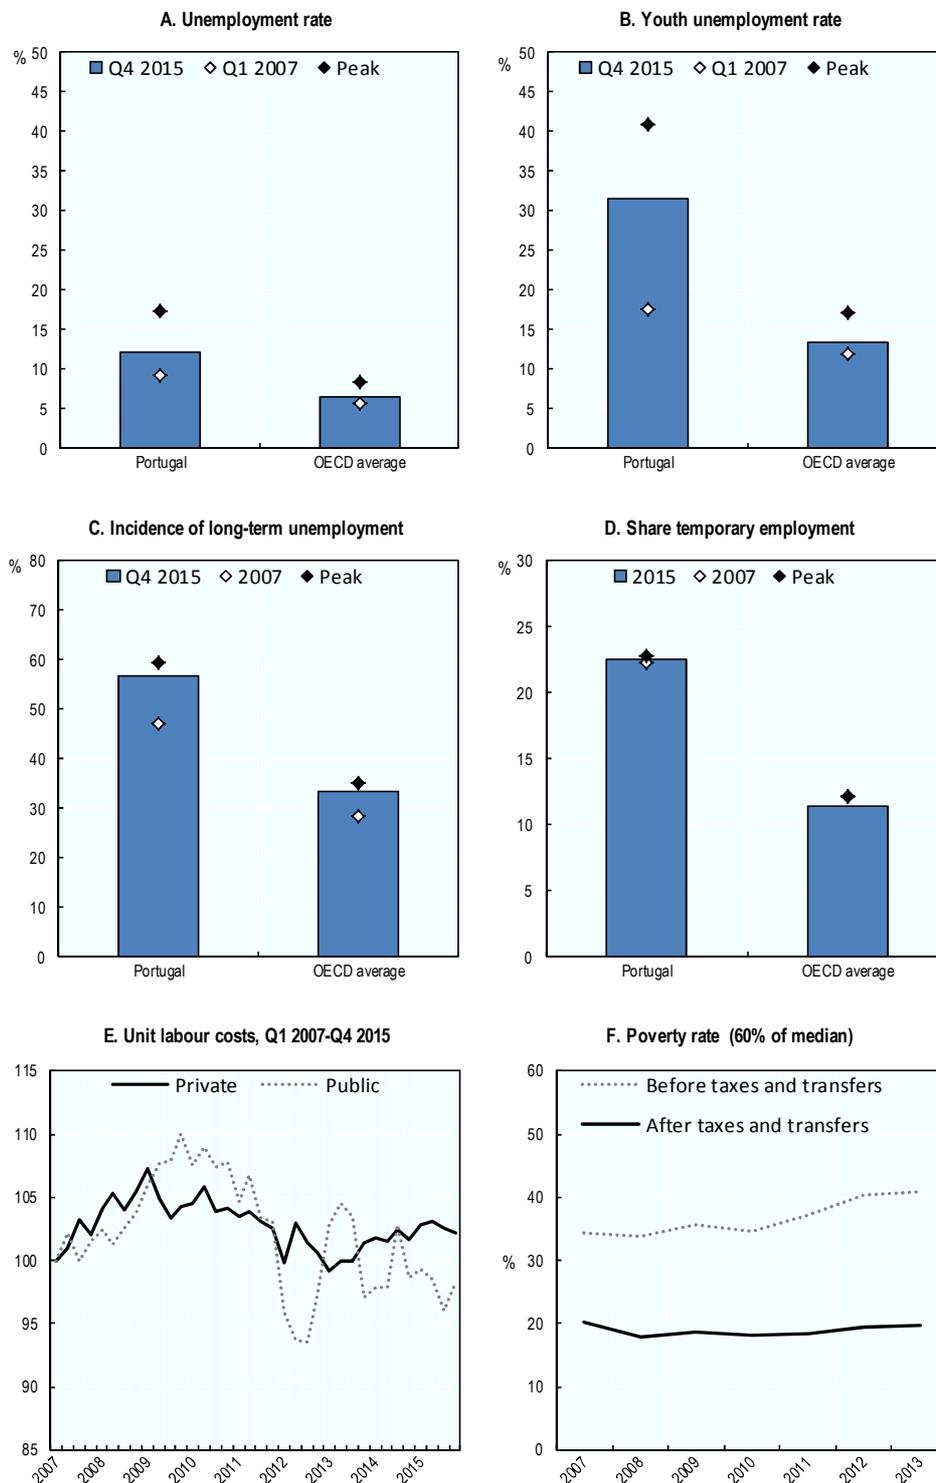

Despite the progress made, many challenges remain and there is a sense in which some reforms may not have gone far enough. The unemployment rate in Portugal remains high, particularly among youth (Figure 2, Panel B). The incidence of long-term unemployment has risen significantly, and has only recently started to fall again (Figure 2, Panel C). The labour market remains highly segmented (Figure 2, Panel D) and, unless further reforms of employment protection legislation are undertaken, this is likely to remain a defining feature of the Portuguese labour market for years to come. In addition, high rates of unemployment have resulted in rising poverty – at least before taxes and transfers are taken into account (Figure 2, Panel F).

Many of the measures undertaken during the crisis helped achieve wage moderation which, at the time of the deep recession, contributed to reduce job losses. They also helped to restore some of the competitiveness of the Portuguese economy lost in the period prior to the crisis, when wages were growing more rapidly than productivity (Figure 2, Panel E). However, the falls in unit labour costs were larger in the public sector (as a result of wage cuts) than in the private sector. In addition, the competitiveness gains in the private sector were driven primarily by improvements in productivity resulting from the exit of least productive firms from the market and the adoption of leaner production processes by surviving and new firms, rather than by falls in average compensation. In general, the evidence presented in this report suggests a high degree of nominal wage rigidity in the Portuguese economy, which could be particularly problematic at times of low inflation since it prevents real wage adjustments from taking place.

Improving employment outcomes in Portugal will hinge on further labour market reforms as outlined in this report. While some measures may require additional resources (e.g. reductions in social security contributions, increased coverage of unemployment benefits) others will provide savings (e.g. reductions in the maximum duration of unemployment benefits, better targeting of ALMPs). In addition, insofar as some of the measures will increase employment, they will also reduce expenditure on benefits while raising tax revenue. Finally, most of the measures proposed (e.g. EPL and collective bargaining reforms) will have an important impact on the labour market without additional cost to the tax payer.

Of course, labour market performance depends not only on employment policies, and there are many other challenges that need to be tackled in order to ensure more and better jobs in Portugal. The last chapter of this report outlines the main ones. First, a return to higher and more sustainable growth remains a critical condition for further improvements in the labour market. Unfortunately, based on current projections, the recovery in Portugal will only allow for some further reduction in the unemployment rate. A key obstacle to higher economic growth in Portugal is product market regulations. Despite significant improvements in this area in recent years, non-tradable sectors such as energy, transport and professional services continue to be characterised by low levels of competition and, given that intermediate inputs from these sectors are one of the most important cost inputs for firms in the tradable sector, the scope for further competitiveness gains and enhanced export performance depend crucially on further reforms in those areas. Growth and job creation in Portugal will also depend on the access that firms have to credit – the cost of which remains high compared to some other OECD countries, including Italy and Spain – as well as on reducing the tax wedge, which weighs heavily on Portuguese companies. Finally, achieving higher levels of productivity (but also inclusiveness) in Portugal will depend critically on the country's ability to upgrade the skills of its workforce, with a particular focus on the least-skilled.

Figure 2. Summary of key labour market developments

*Note:* The unemployment rate is harmonised and seasonally adjusted. Long-term unemployment covers those out unemployed for 12 months or more. The share of temporary employment is estimated as a proportion of all those in dependent employment. Unit labour costs for the private sector refer to the business economy (excluding real estate).

## CHAPTER 1

### LABOUR MARKET REFORMS IN PORTUGAL 2011-2015

Over the period 2011-2015, Portugal carried out a comprehensive package of reforms aimed at reducing labour market segmentation and (long-term) unemployment, on the one hand, while increasing flexibility, competitiveness and resilience, on the other. The reforms included changes to employment protection legislation (EPL), unemployment benefits, activation policies, collective bargaining and working time arrangements. This chapter offers a brief summary of these reforms, together with an analysis of their intended and (where possible) actual impact on the labour market.

The statistical data for Israel are supplied by and under the responsibility of the relevant Israeli authorities. The use of such data by the OECD is without prejudice to the status of the Golan Heights, East Jerusalem and Israeli settlements in the West Bank under the terms of international law.

### **Employment protection legislation on permanent contracts became less stringent, and the gap with temporary contracts was reduced**

Prior to the reforms, Portugal was an outlier on the OECD's employment protection legislation (EPL) indicator for regular contracts, which was driven primarily by: demanding procedural requirements for employers initiating a dismissal process; high severance payments; and the strong likelihood of reinstatement in cases of unfair dismissal. While it is not possible to capture all aspects of EPL in an internationally comparable summary indicator,<sup>5</sup> the OECD measure nonetheless gives a sense of how restrictive regulations for individual dismissal of regular workers were in Portugal compared to most other OECD countries. At the same time, the ease of hiring temporary workers in Portugal was more or less in line with that of the OECD average, meaning that there was a large regulatory gap between temporary and permanent contracts. While not the only determinant, this regulatory gap was an important factor behind the high level of labour market segmentation in Portugal. More generally, restrictive hiring and firing practices acted as a significant barrier to the efficient (re-)allocation of labour resources across the economy.

Between November 2011 and June 2014, Portugal implemented a number of changes to its EPL, including: reductions in severance pay (particularly for permanent contracts); introduction of a new reason for dismissal (inadaptability without change to the nature of the job); and the introduction of more objective (performance-related) criteria for dismissing workers in the case of extinction of a work position (which brought them more closely in line with those used in the case of collective dismissal). These reforms reduced the protection of workers on permanent contracts in Portugal, and narrowed the regulatory gap with workers on temporary contracts. From an international perspective, these reforms rank among the most significant ones implemented in recent years.

Despite these reforms, Portugal's EPL for permanent workers remains the most stringent in the OECD, along with that of the Czech Republic. This is because some of the key difficulties of dismissing permanent workers (discussed in Chapter 3 of this report) were not addressed. Further reforms are therefore highly recommended, especially since there is some early indication that the recent EPL reforms may have encouraged on-the-job search by individual workers, as well as hiring and the share of hiring that is on permanent contracts. The analysis also suggests that significant long-term effects on productivity and growth may be expected from the recent EPL reforms implemented in Portugal.

This section starts with a brief theoretical discussion on the impact of EPL on productivity, growth and labour market duality. It then describes the recent reforms implemented in Portugal, puts them in an international context, and provides some initial evidence on their impact. Long-run productivity and growth gains are also estimated.

### ***Rigid employment protection legislation can harm productivity and growth, and is a key determinant of labour market duality***

Adjusting the level and composition of the workforce to adapt to changing demand conditions and technology is vital for effective businesses operation, and therefore for productivity and economic growth. But job displacement entails significant costs for the workers concerned in terms of earning losses and the possible obsolescence of their job-specific skills and experience. In addition, social costs can also be important (e.g. benefit payments, and expenditure on job-search assistance and active labour market programmes).

Employment protection legislation (EPL), that is the rules governing the hiring and firing of workers, has typically been designed to protect jobs and increase job stability, with the aim of preserving the individual worker and society from some of the above-mentioned costs. A related objective of EPL is to make employers internalise the social cost of dismissing workers – without which the level of turnover

5. See Chapter 2 of OECD (2013c) for further detail on the limitations of the OECD EPL indicator.

would be inefficiently high. However, in some cases, constraints imposed on firms might be excessive, hindering the effectiveness of labour market flows and the allocation of labour to the most productive jobs, thereby harming productivity and growth.<sup>6</sup>

In addition, when there is a large gap in EPL between fixed-term and open-ended contracts, firms have a clear incentive to hire workers on temporary (instead of permanent) contracts, leading to labour market duality. For new entrants to the labour market, this reduces the probability of conversion to a permanent contract, turning fixed-term contracts into a trap rather than a stepping stone to more stable employment. For workers, this reduces incentives to invest in firm-specific skills, raises work-related stress, and lowers motivation. From the firm's perspective, it increases worker turnover and recruitment costs, and also lowers productivity. In addition, firms are less willing to invest in workers who are unlikely to keep their job, further contributing to lower productivity. Finally, large differences in regulations across contracts also tend to concentrate any required labour market adjustments on non-regular workers, thereby increasing labour market segmentation.

Evaluations of past labour market reforms in Portugal have produced evidence broadly consistent with the above theory. In particular, it has been shown that reducing the complexity of procedural requirements for individual dismissal in the case of regular contracts positively affects firm performance (through the indirect effect of employment protection on worker effort) as well as the share of temporary contracts (and therefore labour market segmentation). Box 1 provides further details.

#### Box 1. The impact of previous EPL reforms in Portugal

Martins (2009) assessed the impact of the complexity of procedural requirements in the case of just dismissal on job and worker flows, on wages, as well as on firm performance. He looks at the Portuguese labour law reform of 1989<sup>1</sup> which revised the regulations governing dismissal for disciplinary reasons, setting out a new set of procedural requirements to be followed by employers. A particular aspect of this reform is that it let small firms (employing 20 or fewer workers) follow a much simpler procedure: out of the 12 specific rules that larger firms needed to follow, only four needed to be considered by smaller firms. Comparing small and large employers, Martins (2009) finds no robust evidence that such procedural requirements impact on job or worker flows (although some estimates suggest an increase in hiring), however he does find evidence that stricter procedures reduced firm performance. The author argues that this is because higher protection for workers reduces their effort on the job (although a complementary explanation is that relaxing dismissal requirements allows for better managerial practices).

Along similar lines, Centeno and Novo (2012) look at what happened when a change to the Portuguese Labour Code in 2004 extended the procedural requirements to firms with 11 to 20 workers.<sup>2</sup> They find that stricter regulations for dismissal of workers with permanent contracts result in a higher share of workers on temporary contracts, as well as an increase in excess turnover for these type of contracts. These results therefore provide evidence that a larger gap in employment protection legislation between temporary and permanent contracts results in greater labour market segmentation. Centeno and Novo (2013) use the same natural experiment as Centeno and Novo (2012) and find that increases in protection for permanent workers also reduce the wages of new workers on permanent and temporary contracts, but do not affect the wages of existing workers on permanent contracts.

6. While flexibility-enhancing EPL reforms can have a positive impact on the overall level of employment, this effect tends to be relatively small (OECD, 2006).

### *Portugal implemented a range of measures to reduce employment protection on permanent contracts*

Between November 2011 and June 2014, Portugal implemented a number of EPL reforms, most of which targeted a reduction in the level of protection on permanent contracts. Central among those reforms was a significant reduction in severance pay on permanent contracts, which is now lower than that on temporary contracts (although severance pay on the latter was also reduced). Some preliminary OECD analysis suggests that these changes may have encouraged on-the-job<sup>7</sup> search as well as hiring and the share of hiring that is on permanent contracts. At the same time, because of grandfathering (i.e. the exemption of existing workers from many of the new regulations) – the effect on firing/job separations was limited. Portugal also tried to ease some of the reasons for dismissing individuals on permanent contracts. First, it introduced a new reason for dismissal (inadaptability without change to the nature of the job) – although it is not clear that it will make dismissal for inadaptability (a form rarely used in the past) any easier in practice. Second, Portugal tried to introduce more objective criteria for selecting individuals to dismiss in the case of extinction of a work position (bringing them more in line with those used for collective dismissal). Again, it remains to be seen whether this will make any difference in practice.

#### *Severance pay on permanent contracts was significantly reduced*

Before the reforms, Portugal had one of the highest levels of severance pay for the termination of open-ended employment contracts in the OECD. Regardless of tenure, every worker would be entitled to a minimum of three months' severance pay and there was no upper limit to the amount of severance pay that could be paid out. Severance payments were also higher for permanent than for temporary contracts. Taken together, this system created a significant disincentive for employers to hire workers on permanent contracts, and is likely to have harmed the efficient (re-)allocation of labour resources since firing was very costly for firms and, from the point of view of workers, entitlements to high severance pay (which are job-specific and therefore not portable) would have reduced the incentives to look for a job elsewhere, even if it could have led to a better match.

Over the period of the reforms, severance pay in the case of open-ended contracts was reduced from 30 days of base wage and tenure-based increments for every full year of tenure, to 12 days for every year of tenure. The minimum of three months' severance pay was removed, and ceilings were introduced to cap the maximum amount of severance pay that could be paid out. In the case of temporary contracts, severance pay was also reduced, although to a lesser extent (from three days per month of tenure on contracts lasting six months or less and two days per month of tenure for contracts lasting more than six months, to 18 days per year of tenure, and further to 12 days per year of tenure for contracts lasting more than three years).

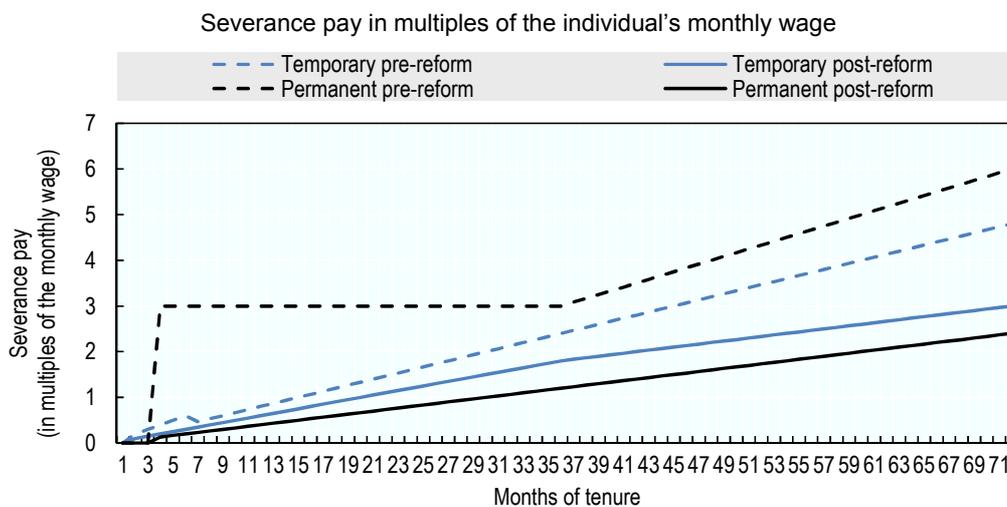

Figure 3 illustrates how the pre- and post-reform rules for severance pay differ, both for temporary and permanent contracts, and over the first 72 months (six years) of tenure.<sup>8</sup> The two key points to take away from this graph are: i) the significant reduction in severance pay on permanent contracts; and ii) that severance pay for permanent contracts was higher than for fixed-term contracts prior to the reform, but is now lower. Both of these effects should encourage hiring on permanent contracts in the future. One caveat, however, is that while the reforms tackled the gap in severance pay between permanent and temporary contracts, they left untouched the difference in procedural costs which, according to some authors (e.g. Centeno and Novo, 2012), present the largest difference between the two types of contract. In addition,

- 
7. On-the-job search may be seen as a lead indicator that is likely to anticipate higher rates of job-to-job mobility (Orsini and Vila Núñez, 2014).
  8. While the standard maximum cumulated duration of successive fixed-term contracts in Portugal is three years, temporary contracts of uncertain duration may last up to six years, which explains the choice of a six-year time period for the graph.

employers will have other incentives to keep on hiring on temporary contracts (see the discussion in Chapter 2 on labour market segmentation for further detail).

The new severance pay rules apply primarily to new contracts. For existing contracts, the rights accrued to date were largely preserved (called “grandfathering”). The reason for doing this was to avoid excessive job losses during the crisis. Indeed, there is growing evidence that EPL reforms engender short-run costs as their immediate impact tends to be greater on separations than on hiring, resulting (on average) in a small initial contraction of employment (e.g. Von Below and Thoursie, 2010). The preservation of severance pay entitlements will therefore have attenuated these short-term costs. On the downside, it also means that the positive effects of the reforms will take longer to manifest themselves. Figure 4 shows estimates of how fast (or rather slow) actual severance pay entitlements are converging with those intended by the new rules. If all workers on permanent contracts still had severance pay entitlements according to the old rules, then the average number of months of severance pay would be 12.2 in Q4 of 2014. If, on the other hand, all workers on permanent contracts had their severance pay entitlements calculated on the basis of the new rules, then they would receive 4.7 months on average. In practice, however, the actual level of severance pay will only slowly adjust downwards, since existing workers kept their built-up entitlements. This means that in Q4 of 2014, workers on permanent contracts were still entitled to 10.6 months of severance pay on average. Some simple linear projections based on the current trend suggest that the new rules will not apply fully until after 2021. In the case of temporary contracts, the adjustment will obviously be much faster since tenure is, by definition, much shorter on such contracts and turnover higher. As shown in Panel B of Figure 4, the new rules already apply entirely in the case of temporary contracts.

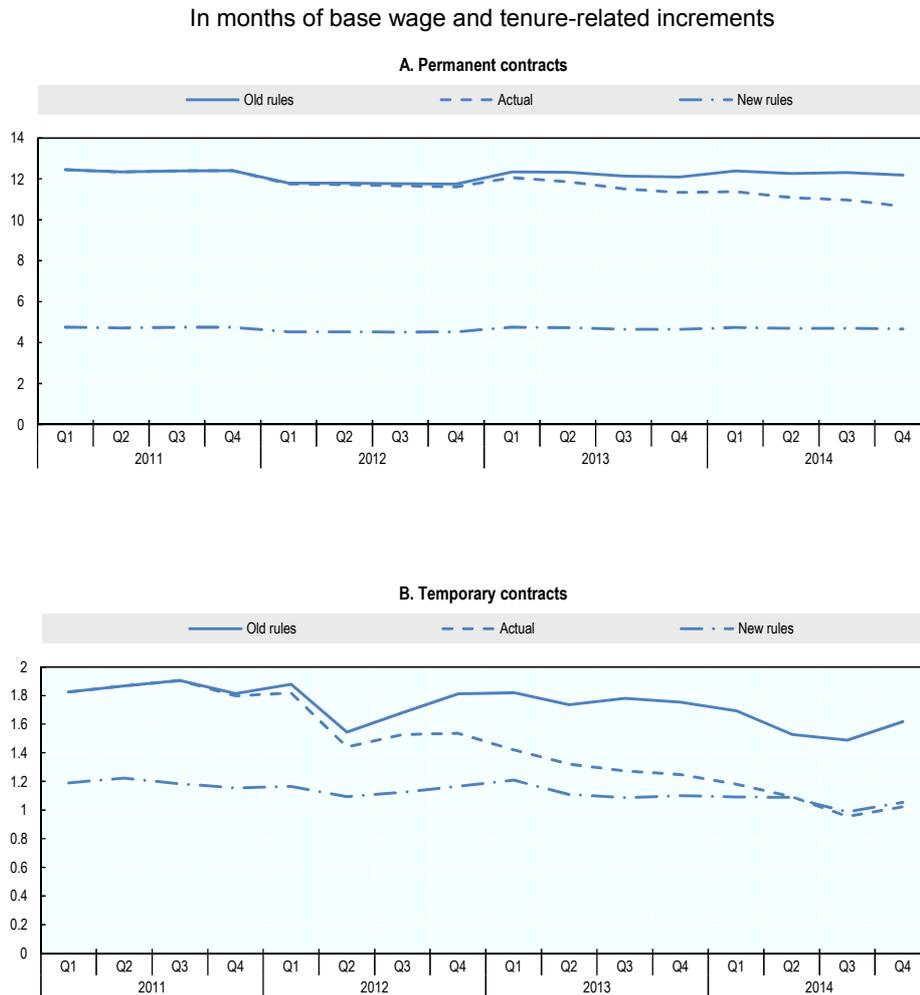

Figure 3. **Severance pay on temporary and permanent contracts before and after the reform**

*Note:* No severance pay is due if the worker is dismissed during the trial period, which is assumed to be 90 days for permanent contracts (although trial periods are longer for certain more demanding professions), 30 days for fixed-term contracts of six months or more, and 15 days for fixed-term contracts of less than six months. The graph does not illustrate the caps on severance pay introduced by the reform. Severance pay may not exceed 12 times the individual's monthly salary, which would be reached after 360 months (or 30 years) of tenure. In addition, the base wage (including tenure-based increments) for calculating the entitlement is capped at 20 times the national monthly minimum wage.

Figure 4. Average severance pay entitlement under the old rules, new rules and actual

*Note:* Quarterly EU-LFS data on start date, contract type and duration of temporary contracts are used to calculate the number of months of severance pay entitlement for each individual based on the information from Table A1. Given that the EU-LFS does not contain information on wages, the upper limits for severance pay are only applied in terms of the maximum number of months (i.e. 12) and not in terms of the maximum base wage (i.e. 20 times the minimum wage). Given that very few employees have wages higher than 20 times the minimum wage, the severance pay calculation will not be strongly affected by this simplification.

*Source:* OECD analysis based on the EU-LFS.

Despite the preservation of accrued severance pay rights, there is some early indication that the reforms of severance pay may have had a positive effect on on-the-job search, hiring and the share of hiring that is on permanent contracts (see Box 2). In addition, there is evidence that the grandfathering has mitigated the impact of the reform on job separations (although it introduced some inequalities between workers, depending on when they signed their contract).<sup>9</sup>

The reforms also introduced changes to the way severance payments are to be made. A dismissal fund (*Fundo de Compensação do Trabalho* – FCT) was set up which collects compulsory monthly contributions from employers into a savings account linked to each worker.<sup>10</sup> The purpose of the fund is to cover up to 50% of the severance pay in case of dismissal. Since October 2015, payments to the fund stop when this amount has been reached. When a worker is dismissed, the fund pays the part of severance pay that has been saved up, and the employer pays the remaining part. While the fund does not affect the overall cost of dismissal, it at least reduces the up-front cost as well as the liquidity risk of high severance payment obligations. If the worker leaves of his/her own accord, the employer can obtain a refund of the total amount saved up in that worker's account.

In addition, an insurance fund (*Fundo de Garantia de Compensação do Trabalho* – FGCT) was set up to protect workers in case the total amount of severance pay the employer can afford and the part paid by the FCT do not add up to 50% of what the worker is entitled to. The FGCT basically ensures that the worker receives at least 50% of the severance pay entitlement, and this is independent of the fund's performance (so the financial risk is borne entirely by the fund and the employers, and not by the workers).

While the new Portuguese system for severance payments reduces the up-front cost of dismissal to the employer and offers some insurance to the employee, it does not solve the problem that high accumulated severance pay rights act as a disincentive to mobility on the part of the worker. In this sense, the Portuguese system is very different from, for example, the Austrian severance pay system introduced in 2002, in which employers contribute to an individual worker's account which is transferrable from one employer to another. Upon retirement, employees can claim the remaining entitlements built up in their account as a cash payment or convert them into an annuity. By making accumulated severance payments entirely transferable from one employer to another, the Austrian solution eliminates obstacles to worker mobility. That being said, the Austrian system has the disadvantage that the financial risk in case the fund underperforms is borne entirely by the worker. In addition, the system is more expensive and therefore increases labour costs.

- 
9. The immediate positive effect on hiring combined with the delayed effect on firing is reminiscent of the transitional “honeymoon” job-creating effect described by Boeri and Garibaldi (2007) in the context of two-tier labour market reforms which liberalised the use of temporary contracts while leaving largely unchanged the legislation applying to the stock of workers employed under permanent (open-end) contracts. Their model predicts that there would be an immediate effect on hiring and therefore short-run employment gains, but that the latter would eventually be dissipated by the decline of insider workers.
10. In practice, these contributions are waived for the first two years of the existence of the fund (or until the employment contract is terminated, whichever comes first) through the temporary Employment Incentive measure (*Incentivo Emprego*).

### Box 2. The impact of severance pay reforms in Portugal on on-the-job search and worker flows

The primary objective of the severance pay reforms carried out in Portugal over the period 2011-2013 was to encourage a more efficient re-allocation of labour resources. With lower severance pay entitlements, workers might be less reluctant to switch jobs, resulting in increased on-the-job search and job-to-job flows. For employers, lower severance pay could increase both hiring and firing rates. However, because accumulated severance pay entitlements were largely preserved by the reform, one would expect the largest (short-run) effects to be on hiring only (and possibly on the firing/job-to-job moves of new hires). In addition, because the reduction in severance pay was larger for permanent than for temporary contracts, one might expect to see an increase in the share of hiring that is on permanent contracts. At the same time, it is important to remember that severance pay was cut for both types of contract, and so the reform should have encouraged hiring on temporary as well as on permanent contracts.

New OECD analysis carried out in the context of this project uses the European Labour Force Survey and the Portuguese *Quadros de Pessoal* (a linked administrative employer-employee dataset) to shed some initial light on the impact of the reforms on on-the-job search and worker flows. The intuition behind the analysis is to assess whether workers and employers most deeply affected by the changes in severance pay have the greatest change in behaviour in line with what the theory would predict. For example, one would expect to observe a higher probability of on-the-job search for those individuals for whom the difference between actual/current severance pay and that which they would have received under the old rules is greatest. Similarly, employers might be more likely to fire workers for whom the reforms have meant the greatest reduction in severance pay (as measured by the difference between actual severance pay and what they would have been entitled to under the old rules). As far as hiring is concerned, employers will be more forward-looking and interested in the new rules (applying to new hires) rather than the actual rules (applying to existing workers). In this case, one would expect to see more hiring among employers where the difference in severance pay between the old and new rules is the greatest. Finally, one might expect to see an increase in the share of hiring that is on permanent contracts amongst those employers who saw a larger fall in severance pay for permanent workers than for temporary ones.

While a range of different models are run with different dependent variables and on different datasets (full details can be found in Annex C), the basic approach is to estimate an equation of the following type:

$$Y_{it} = \beta_0 + \beta_1 SP_{it} + \sum_{c>1} \beta_c X_{cit} + \gamma_t + \delta_g + \varepsilon_{it}$$
