Where:  $Y_{it}$  is the outcome of interest (on-the-job search, job separations/employment outflows, hiring, share of permanent hiring) for individual, firm or occupation  $i$  at time  $t$ ;  $SP_{it}$  is a variable which measures the extent to which the individual/firm/occupation was affected by the severance pay reform;  $X_{cit}$  are a range of individual, firm or occupation characteristics. All specifications also include fixed effects for time ( $\gamma_t$ ) and, depending on the model run, occupation/firm fixed effects ( $\delta_g$ ). Because the models explore three separate reforms (1 November 2011, 1 November 2012, and 1 October 2013) which affect different groups in different ways, they may be thought of as a difference-in-differences set-up.

The results (presented and discussed in full in Annex C) largely confirm the predictions of the theory and indicate that the reforms: promoted on-the-job search; encouraged hiring (although these results are less robust); increased the share of hiring that is on permanent contracts; and had no noticeable effect on outflows from employment into unemployment and inactivity. The effects also appear to be larger for small firms than for large ones.

Some additional and different analysis (also presented in Annex C) indicates that job separations were more likely for individuals hired just after the reform than for those hired just before – and this effect appears to be driven primarily by separations which are at the employer's initiative (i.e. firing). These results indicate that the preservation of accumulated severance pay rights for existing workers successfully mitigated the short-run effect of the reforms on their likelihood of being fired. At the same time, however, this "grandfathering" introduced some inequalities in the labour market, depending on when workers signed their contract.

While these results are interesting and broadly consistent with what the theory would predict, they need to be interpreted with care because: i) the reforms were implemented very recently and their full impact on the labour market might not be observable yet; ii) the nature of the reforms means that it was not possible to identify clear treatment and control groups, and therefore the causality of the observed effects cannot be established with full certainty. On the other hand, the findings are surprisingly consistent across models and datasets, as well as robust to a falsification exercise. Either way, further research will be required to ascertain the findings obtained here.

*A new reason for dismissal was introduced: Inadaptability without change to the nature of the job*

Another characteristic of Portuguese labour law prior to the reforms was the relatively strict definition of fair dismissal in the case of regular contracts, which derives from the Constitution itself, and which made it very difficult, in practice, for employers to dismiss workers on open-ended contracts.

Prior to the reforms, a worker in Portugal could be dismissed for inadaptability if, following a change in the nature of the job (e.g. as a result of technological change or the adoption of new production/sales practices), s/he showed a continuous fall in productivity or in the quality of the work performed, which could not be remedied by additional training and a period of adaptation on the job. In addition, the employer needed to prove that there was no other, suitable position that the worker could be offered instead (*repêchage*). The difficulty of proving the existence of these conditions (and the ensuing legal uncertainty) meant that this form of dismissal was rarely used in practice (MTSS, 2007; Monteiro Fernandes, 2012; Pestana Nascimento, 2012; Phalempin, 2014).<sup>11</sup> Analysis of Social Security data especially provided for this report suggests that inadaptability accounted for less than 1% of job separations prior to reform (Figure 5).

To give employers more flexibility, the reforms introduced a second type of dismissal for inadaptability: that which does not require a change in the nature of the post and which, therefore, is more closely aligned with the concept of dismissal for “unsuitability”. This form of dismissal also no longer requires the employer to prove that there was no other position that the worker could have been moved to instead (*repêchage*).

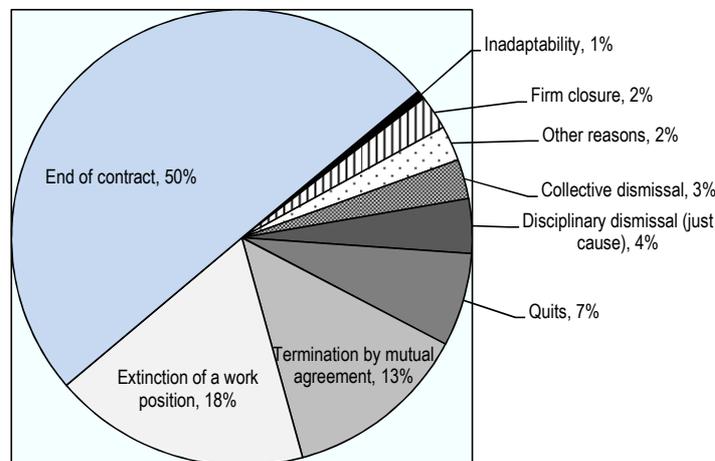

While it remains to be seen how these new regulations will be interpreted by the courts in practice, initial reactions by lawyers indicate that dismissing a worker for inadaptability (even without change in the nature of the post) will remain difficult in Portugal (Monteiro Fernandes, 2012; Phalempin, 2014). First, the procedure remains complicated (including notification and consultation procedures), and proving that a worker’s productivity or quality of work has significantly declined will remain difficult. Second, even though the new form of dismissal for inadaptability does not require the employer to prove that there was no other, suitable position available, this may make little difference in practice. This is because Article 53 of Portugal’s Constitution, which guarantees workers “security of employment” and prohibits “dismissals without just cause”, has traditionally been interpreted in a very strict sense as meaning that the employment relationship can only be terminated as a last resort, in situations where all other options have already been explored. That being said, the reform might at least send a signal to employees that the preservation of an employment relationship will, from now on, depend to a larger extent on their maintaining a satisfactory level of productivity.

---

11. According to Pestana Nascimento (2012) the conditions that needed to be fulfilled for dismissal on the grounds of inadaptability were so demanding that, until the change in the law in August 2012, only two judgments were pronounced on the matter.

Figure 5. **Reasons for job separations, first six months of 2012**

#### *Dismissal for extinction of a work position: Closer alignment with the rules for collective dismissals*

Prior to the reforms, employers in Portugal had to follow strict seniority-based (“last in, first out”) rules to select a worker to be dismissed in case of extinction of a work position. This made it difficult for employers to adjust their workforce in accordance with their business needs. In particular, it meant that dismissals were not necessarily based on worker productivity. These requirements for individual dismissal stood in stark contrast to those for collective dismissal, where employers could define their own criteria for selecting the workers to be dismissed. Anecdotally, this encouraged small firms (fewer than 50 employees) to opt for collective dismissal instead given that, in Portugal, such firms need to dismiss just two workers for the dismissal to be classified as collective.

The reform tried, but failed (as a result of a decision of the Constitutional Court) to allow employers to also select their own criteria for individual dismissal in case of extinction of a work position. The government then had another go at re-defining the criteria, and the end result is a new set of rules which moves away from seniority-based criteria, to ones based on performance and cost. In this sense, the criteria were at least more closely aligned with those that employers would tend to choose in the case of collective dismissal. Again, however, it remains to be seen how these will be applied in practice by the courts. In particular, there appears to be concern among some commentators that performance-related criteria remain too subjective and therefore difficult to assess by the courts.<sup>12</sup> That being said, the legal system does not appear to have had much trouble to date in assessing the criteria chosen by employers in the case of collective dismissal (Carvalho Martins, 2014) – so these concerns may be exaggerated.

12. Which may lead to another rejection by the Constitutional Court (Távora and González, 2015).

Dismissal for extinction of a work position is also subject to the *repêchage* condition – i.e. the need to prove that there was no other suitable position that the employee to be dismissed could have been moved to. While the reform tried to remove this condition, the Constitutional Court ruled it unconstitutional.

***These changes have significantly reduced Portugal’s EPL – but much remains to be done***

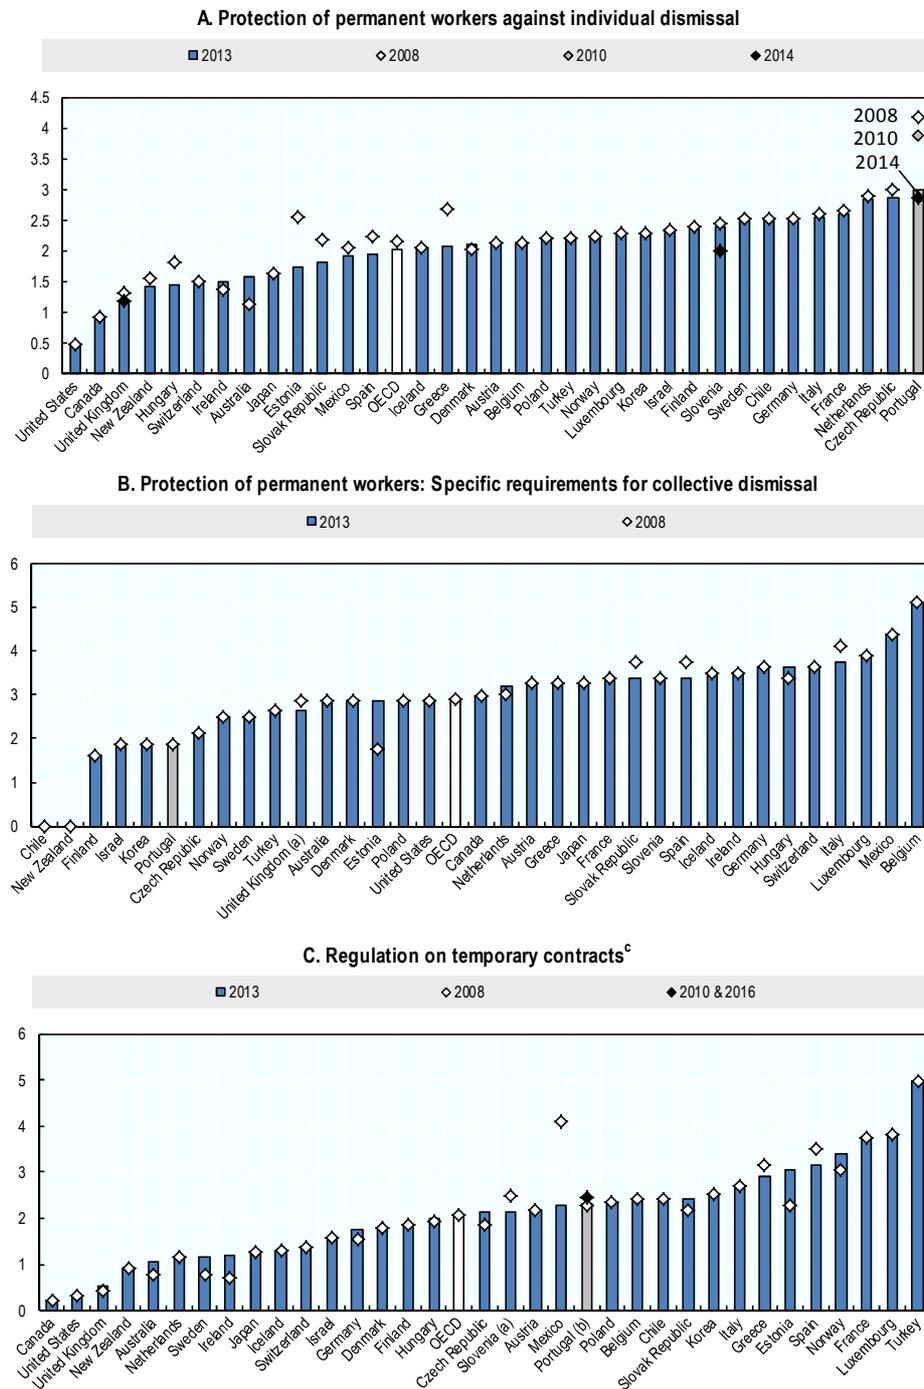

The importance of the reforms described above can be analysed using the OECD indicators of employment protection legislation (EPL), which measure the procedures and costs involved in dismissing individuals or groups of workers and the procedures involved in hiring workers on fixed-term or temporary work agency contracts. Using this indicator, Figure 6 shows how the stringency of EPL evolved between 2008 and 2013 in OECD countries, and also provides provisional data for Portugal for the years 2014-2016 (where these are different from 2013). The stringency of EPL is shown separately for: i) individual dismissals of workers on permanent contracts (Panel A); ii) additional provisions for collective dismissals (Panel B); and iii) hiring on temporary contracts (Panel C). The comparative analysis shows that, following a trend common across many other OECD countries, the employment protection for permanent workers against individual dismissal has been significantly reduced in Portugal over the period 2008-2013. Despite this, the stringency of EPL for permanent workers remains the highest in the OECD, along with that of the Czech Republic. In the final chapter, some of the reasons behind this difference will be explored, along with further options for reform. Additional requirements for collective dismissal (e.g. notification requirements and additional delays) have always been relatively light in Portugal compared to other OECD countries, and this continues to be the case (Panel B).<sup>13</sup>

Finally, Panel C shows that hiring on temporary contracts in Portugal continues to be only marginally more difficult than in the OECD on average. During the crisis, regulation on temporary contracts in Portugal was reduced slightly, which reflects a measure which allowed exceptional renewals of temporary contracts. While the standard maximum cumulated duration of successive fixed-term contracts in Portugal is three years, two exceptional extensions of temporary contracts were permitted during the reforms. The first of these came into force on 11 January 2012 and allowed two additional extensions (not exceeding 18 months overall) of all fixed-term contracts that were set to reach the maximum duration limit by the end of June 2013. The second exceptional renewal came into force on 8 November 2013 and allowed all fixed-term contracts that would reach the maximum duration limit by 7 November 2015 to be extended twice (but not exceeding 12 months overall). As pointed out by Carvalho Martins (2014), this led to a situation where, in the most extreme case, fixed-term contracts of pre-defined duration could last for a total of five and a half years. While the purpose of these temporary extensions was to mitigate the impact of the crisis on unemployment, they may also have reduced the desired impact of the reforms on labour market duality in the short-run.

---

13. If anything, Figure 6 overestimates the difficulty of collective dismissals in Portugal. This is because the OECD EPL indicator is calculated as the sum of various components which measure the additional difficulty of collective dismissal over individual dismissal. The lowest score on each of these indicators is zero, and no negative values are allowed where collective dismissal is easier than individual dismissal (as is the case in Portugal).

Figure 6. Changes in the OECD indicators of employment protection, 2008-2013

- 2014 instead of 2013.
- The lower value for Portugal for 2013 reflects the temporary measures which allowed extraordinary renewals of temporary contracts.
- This captures the relative difficulty with which employers can hire workers on temporary contracts.

### ***Expected effect on productivity and growth***

As shown in the previous section, the EPL reforms in Portugal were significant, implying a 0.93 point fall in the OECD EPL indicator. By way of comparison, the 2012 labour market reform in Spain resulted in just a 0.44 point fall in this indicator. One would expect reforms of this type to have an impact on labour productivity growth by improving the allocation of labour resources and reducing labour market duality. However, as argued above, the preservation of severance pay rights means that the impact on productivity will take time to materialise and so the immediate effect is likely to be small and therefore difficult to measure.

It is nonetheless possible to obtain an educated guess of what the potential long-term effects on productivity and growth of the Portuguese EPL reforms are likely to be, by using estimates previously obtained in the economic literature. For instance, Bassanini, Nunziata and Venn (2009) use industry-level data for 16 OECD countries over a period of more than 20 years and show that a reduction of half a point on the OECD EPL indicator for individual and collective dismissals raises multi-factor annual productivity growth in the business sector (excluding agriculture, mining, energy, real estate and professional services)<sup>14</sup> by 0.45 percentage points and labour productivity growth by 0.3 percentage points.

Using these estimates, one would therefore expect labour productivity growth in Portugal to increase by as much as 0.56 points once the reforms fully take effect. If in addition it is assumed that the share of the business sector (excluding agriculture, mining, energy, real estate and professional services) is 53% (i.e. equivalent to its 2010, pre-reform level), and that there is no impact of the EPL reforms on employment and productivity in other industries, one would expect a 0.30 point increase in annual GDP growth.

### ***Other reforms and measures in the area of employment protection legislation***

While these will not have impacted on the OECD's indicator for employment protection legislation, a few other changes and measures have been implemented in the past few years in the area of EPL, including: additional measures to tackle dependent self-employment and changes to contracts of very short duration.

#### *Additional measures to tackle dependent self-employment have been taken*

One way in which increasing labour market duality manifested itself in Portugal was through a rise in dependent self-employment (so-called “false” self-employment or *falsos recibos verdes*<sup>15</sup>). These are situations in which the worker is formally self-employed, but the conditions of work are *de facto* similar to those of employees. For the employer, such a contractual relationship offers obvious advantages in terms of lower costs and risks.<sup>16</sup> For the worker there may be some advantages as well (e.g. the possibility of negotiating higher fees), but in practice this depends on the worker's bargaining power (which is often very low, given the lack of union representation) and frequently comes at the cost of significant reductions in social protection and job security. Because of the vulnerability that such employment relationships put workers in, many countries have legislation in place which aims to protect them, including conditions under which an employment contract would be presumed and the self-employed person considered a wage earner of the employer.

14. These industries were excluded by Bassanini, Nunziata and Venn (2009) due to the difficulty of accurately measuring multi-factor productivity growth in those industries.

15. The *Recibos Verdes* were introduced in Portugal in 1978 and were initially targeted at the liberal professions only. However, the great flexibility of the system meant that their use expanded considerably beyond their initial purpose (COE, 2015), and with it cases of abuse. Employers are not required to pay any social security contributions (which are paid by the employees), paid holidays or tenure-related salary increments.

16. Such types of working arrangements might also be used by employers to introduce additional competition for existing workers and thereby stymie wage demands and rises.

In 2012, it was estimated that nearly one in ten self-employed workers (with no employees) in Portugal was in a dependent self-employment relationship (ILO, 2014). While Portuguese labour law already defined the conditions under which an employment contract would be presumed, the reforms gave labour inspectors (*Autoridade para as Condições do Trabalho* – ACT) additional tools for enforcing the existing regulations and regularising contracts in cases of non-compliance. However, some may question what difference these new measures will make on the ground given that the ACT appears to struggle with a lack of resources to do its job effectively (Martins, 2015) and the recruitment of 80 new labour inspectors announced as part of the 2016 budget is certainly a move in the right direction.<sup>17</sup> That being said, the number of labour inspectors remains low in Portugal (307 in 2015), particularly given the fact that most firms in Portugal are SMEs.

#### *Contracts of very short duration*

The Portuguese Labour Code specifies a special form of temporary contract of very short duration (*muito curta duração*) which can be used for the purposes of seasonal agricultural activities or the organisation of touristic events. This contract is not subject to written form, although its celebration should be communicated electronically to social security. Prior to the reforms, these contracts could last no longer than a week, with a limit of 60 days over a period of 12 months. The length of these contracts was increased to 15 days, and the overall annual limit to 70 days.

#### **Access to unemployment benefits has been eased, but their generosity reduced to incentivise a more rapid return to work**

Unemployment benefits provide essential protection for workers against the loss of income from work, thus allowing them to smooth consumption as they engage in job search. In this sense, unemployment benefits have a welfare-enhancing role. In addition, by “buying time” for the unemployed, such benefits enable job searchers to find work that better matches their skills and experience. From a macroeconomic perspective, consumption smoothing acts as an automatic stabiliser. However, benefits, particularly where they are generous (in terms of replacement rates and duration), can also create disincentives for recipients to look for and take up work (OECD, 2006; Tatsiramos and van Ours, 2012; Venn, 2012) and therefore lengthen unemployment spells.

Prior to the reforms, Portugal had a relatively generous unemployment benefit system compared to other OECD countries, which is likely to have contributed to a high rate of long-term unemployment. To address this issue, Portugal lowered the cap on the maximum benefit amount and introduced a declining replacement rate to incentivise a more rapid return to work. In addition, the maximum duration of unemployment benefits was shortened – although this would only apply from the second unemployment spell onwards, so that an element of protection was kept in place during the recent episode of high unemployment. Unfortunately, this also means that the impact of the reform on long-term unemployment will take time to materialise. While it was possible to estimate the impact of the lowering of the cap and the introduction of the declining replacement rate, the early evidence appears inconclusive: the estimates indicate that these reforms have increased exits to employment, but they are all statistically insignificant. The reforms have nevertheless moved Portugal closer to the OECD average in terms of the generosity of unemployment benefits and, if past experience is anything to go by, they should eventually help shorten unemployment spells and reduce the level of long-term unemployment. That being said, the average maximum duration of unemployment benefits remains relatively high in Portugal compared to the OECD average.

---

17. Three years after Law No. 63/2013 came into force, ACT detected a total of 2 488 irregular workers. Many cases were voluntarily regularised by the employer (33.6% in 2014 and 60.9% in 2015) and the proportion of cases reported to the Public Prosecutor's Office reduced from 28.1% of the total cases detected in 2014 to 13.4% in 2015.

At the same time, with soaring unemployment rates and EPL reforms which made it easier for employers to dismiss workers, there was a need to widen the safety net provided by unemployment benefits, which Portugal achieved by relaxing the contribution/employment requirements for unemployment insurance. The evidence suggests that, despite a significant increase in unemployment between 2011 and 2013, the coverage rate of unemployment benefits held up well (and even increased slightly) over the same period. Since 2014, however, there has been a slight fall in the coverage rate, which is probably related to the increase in the number of long-term unemployed (and individuals running out of unemployment benefit).<sup>18</sup>

### ***Access to unemployment benefits was made easier, but their generosity declined***

In Portugal, unemployment insurance (*Subsídio Desemprego* – SD) is available to all individuals with sufficient contribution history, and the benefit amount is estimated as a proportion of previous earnings while duration increases with age and contributory history. Those who are not entitled to unemployment insurance may be entitled to unemployment assistance (*Subsídio Social de Desemprego Inicial* – SSDI) as long as they meet the necessary contribution conditions (which are less stringent than for unemployment insurance) and pass the means test. Unemployment assistance benefit amounts are linked to the social support index (*Índice dos Apoios Sociais* – IAS) and depend on family type, while duration is calculated in the same way as for unemployment insurance. Unemployed individuals who exhausted the maximum duration of unemployment insurance may also be entitled to unemployment assistance (*Subsídio Social de Desemprego Subsequente* – SSDS) as long as they pass the means test. In the case of SSDS, the duration is equal to half the duration individuals were entitled to under unemployment insurance.<sup>19</sup> Finally, the *Rendimento Social de Inserção* (RSI) is a means-tested benefit of last resort.

In 2012, Portugal introduced reforms which facilitated access to unemployment benefits, while reducing their generosity (both in terms of duration and the replacement rate):

1. *Entitlement.* Access to unemployment insurance was made easier by lowering the necessary contributory history from 450 to 360 days over the past 24 months.
2. *Duration.* Maximum benefit duration was reduced from 900 to 540 days (depending on contributory history and age) – although additional increments based on contributory history were maintained, meaning that benefit duration for those with a long contribution history (and especially those aged over 50) could exceed this maximum. In the interest of protecting workers during the current crisis, the new rules would only start applying from the individual's second unemployment spell after the reform onwards. In the case of individuals aged 40 or over, the duration of unemployment assistance was increased (again, from the second unemployment spell onwards).
3. *Replacement rate.* The maximum amount of unemployment insurance that an individual could receive was reduced from three times the IAS to 2.5 times the IAS (but there was a temporary increase of 10% in unemployment insurance for individuals in workless households). In addition, Portugal introduced a declining replacement rate rule for unemployment insurance which meant that benefits would be reduced by 10% after six months to encourage greater job search effort.<sup>20</sup>

18. Note that an increase in long-term unemployment does not mean that the shortening of maximum benefit duration was not effective. Indeed, the rise in long-term unemployment may have been even steeper in the absence of the reforms.

19. Unemployment assistance may be renewed until the pensionable age is reached provided that: i) when unemployment begins, the insured person is aged 52 or over; and ii) by the time of its renewal, the insured person continues to meet the qualifying conditions.

20. In systems (like the Portuguese) where individuals are moved onto (less generous) unemployment assistance upon exhaustion of their regular unemployment insurance entitlement, there is, technically speaking, already

Another initiative the government took to encourage a return to work was to allow the unemployed to keep part of their benefits (50% during the first six months and 25% for the subsequent six months, within certain limits) if they accepted a full-time low-paid job.<sup>21</sup>

Finally, and in addition to the measures outlined above, the government introduced a contributory system of unemployment protection for self-employed workers who work mainly with only one contracting entity. Those who have exercised a dependent self-employment activity for at least 24 months out of the 48 preceding the termination of a service agreement, are now entitled to unemployment benefits. The generosity of these benefits depends on the individual's prior earnings, while the duration is linked to the individual's age and past labour market attachment. The system is financed through a 5% tax paid by employers. More details about the scheme can be found in Annex A. Of course, because entitlement would need to be built up to gain access to this benefit, its impact will only be noticeable in the medium- to long-term (Silva and Pereira, 2012).

***The reforms brought the generosity of Portuguese unemployment benefits closer to the OECD average, although maximum duration remains high***

As this section will show, Portugal had a relatively generous unemployment benefit system compared to other OECD countries prior to the crisis, both in terms of the replacement rate and the maximum duration of benefits. On both aspects, the reforms brought the generosity of the Portuguese unemployment benefit system more in line with that of other OECD countries, although maximum duration of unemployment insurance remains relatively long in Portugal compared with other OECD countries. At the same time, it was relatively more difficult in Portugal to gain access to unemployment insurance (due to longer contribution history requirements), and the reforms aligned the Portuguese system with standard practice across the OECD.

*Maximum duration of unemployment insurance*

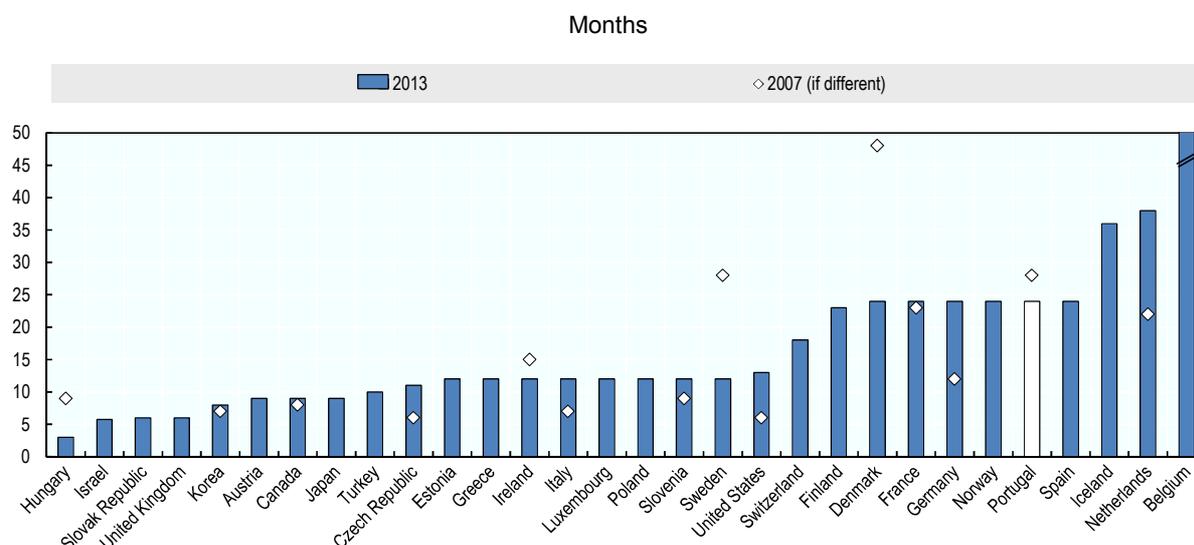

While Portugal reduced the maximum duration of unemployment insurance, it remains long compared to other OECD countries (Figure 7). In the median OECD country, the maximum duration of unemployment insurance is 12 months, compared to 24 months in Portugal. While Belgium is the only country where the duration of unemployment insurance is unlimited, it is important to point out that in many countries the duration of unemployment benefits is *de facto* unlimited because, once individuals run out of unemployment insurance, they are moved onto unemployment assistance which often can be claimed indefinitely (albeit with lower replacement rates and subject to a means test, so that coverage will be much lower). This is the case in Austria, Finland, Germany, Ireland, and the United Kingdom. In Australia and New Zealand, where no unemployment insurance exists, individuals are entitled to unemployment assistance for an unlimited period of time.

---

a built-in declining benefit schedule (conditional on a means test, which often excludes those with a working spouse, for example).

21. It was already possible (since 2006) to keep part of one's unemployment benefit when working part-time. The new measure just extends this possibility (with different rules for the calculation of the benefit) to low-paid full-time jobs. Note that, in Portugal, the entitlement to continued UB payments is conditional on relatively restrictive rules around the type of work and the income from that work. By comparison, Japan's reemployment bonus allows people to keep part of their remaining benefit entitlement regardless of the type of job they move into.

Figure 7. Maximum duration of unemployment insurance, 2007-2013

Note: For Israel, maximum duration is shown for individuals with at least three dependents. In Denmark, the duration is 24 months in three years. In Belgium, the duration is unlimited. In Chile (not shown), the unemployed withdraw from an individual savings account for as long as their balance permits. For Portugal, the duration shown is estimated for a 40-year-old individual and includes additional increments based on contributory history (i.e. 720 days = 540 days + 4 x 45 days).

Source: OECD Social Policies and Data, Policy Overview Tables, Unemployment Benefits.

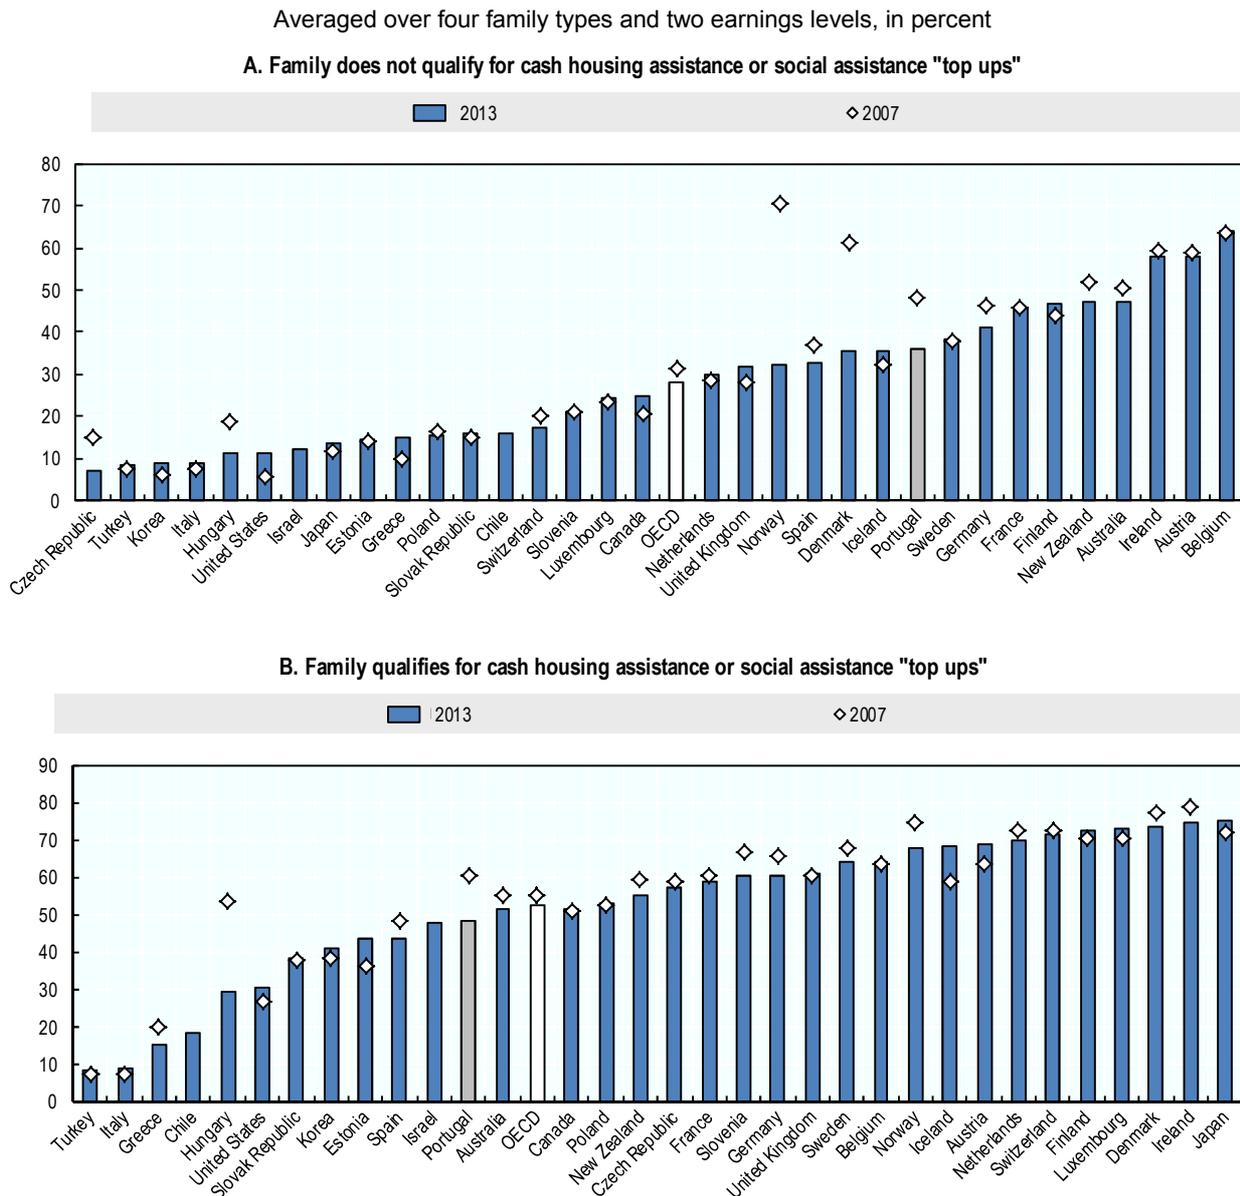

### Replacement rate of unemployment benefits

The generosity of unemployment benefits in Portugal, measured in terms of the replacement rate (i.e. the proportion of income in work that is maintained after job loss), has also moved closer to the OECD average (Figure 8, Panel A). Portugal lowered the maximum amount of unemployment insurance that an individual could receive and also introduced a reduction in benefits after six months of unemployment. Figure 8 shows the net replacement rate<sup>22</sup> (i.e. after taxes and benefits) in Portugal and other OECD countries, averaged across four different household types,<sup>23</sup> two different earnings levels,<sup>24</sup> and over 60 months of unemployment. Between 2007 and 2013, unemployment benefits across the OECD became, on average, less generous – although there are several exceptions (particularly countries where unemployment benefits were not very generous to start with). There was a significant reduction in the generosity of unemployment benefits in Portugal, which aligned them more closely with the OECD average.

22. Comparing the generosity of unemployment benefits across countries as measured by the “replacement rate” is complicated by the many different factors that countries consider when calculating an individual’s entitlement to unemployment benefit (e.g. length of unemployment spell; choice of reference earnings; floors and ceilings for unemployment benefits; number of dependents; age; interactions with the rest of the tax/benefit system; etc.) Besides differences across countries in how such benefits are calculated, these calculation rules also mean that there will be not just one, but many different replacement rates within each country. To circumvent some of these issues, the OECD computes replacement rates for “typical” worker and household cases, depending upon whether they are single or married, have children or not, for different levels of previous earnings (67%, 100% or 133% of average earnings), and for different phases of the unemployment spell.
23. Single person without children, one-earned married couple without children, lone parent with children, one earner-married couple with children. Most Portuguese households are composed of two earners with (36%) or without (24%) children.
24. For full-time earnings of 67% and 100% of average earnings.

Panel A looks at the replacement rate of unemployment benefits only, which shows that they remain slightly more generous than in the OECD, on average. However, the unemployed are entitled to other benefits, including housing benefits and social assistance (like the RSI in Portugal). Once these benefits are taken into account as well, the replacement rate in Portugal is actually slightly below the OECD average (Figure 8, Panel B). One issue here is the generosity of the RSI, which was significantly reduced in recent years and led to a large decline in the number of beneficiaries. This is something which will be further discussed in Chapter 2 of this report.

Figure 8. **Unweighted average of net replacement rates over 60 months of unemployment, 2007-2013**

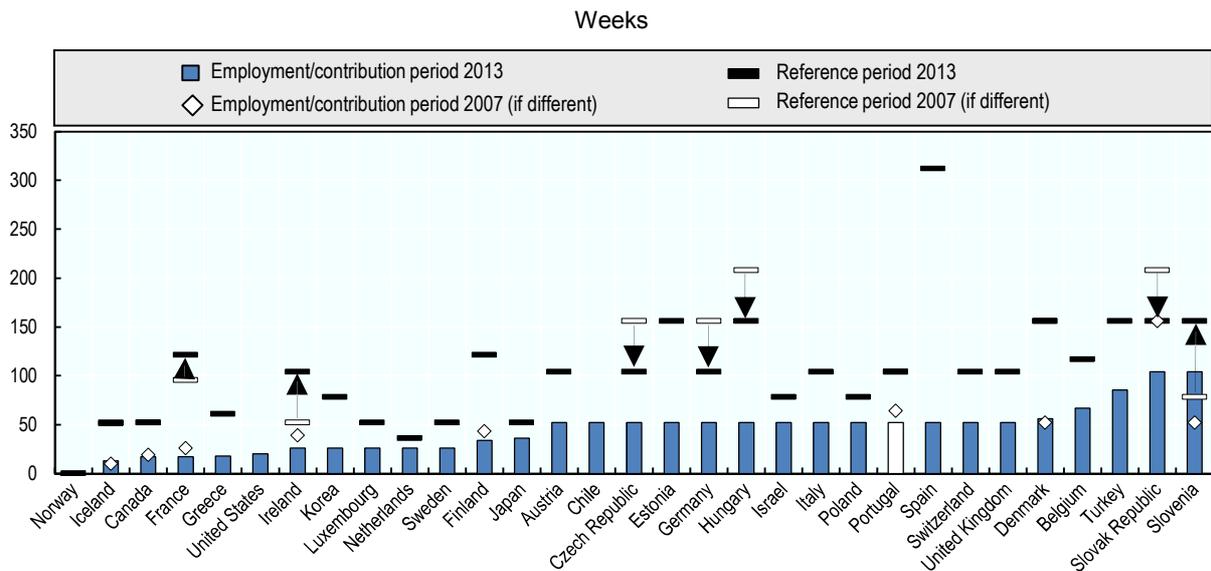

Source: OECD Tax-Benefit Models (revised 18/09/2015).

### Employment/contribution requirements for unemployment insurance

The ease of access to unemployment insurance is determined both by the employment/contribution requirements as well as by the reference period over which these contributions are calculated. Prior to the reforms, Portugal's contribution requirements were slightly higher than those generally observed across the OECD, but the reforms have brought these more in line with standard practice (i.e. around 12 months of contributions) – Figure 9. The reference period over which these contributions are estimated has not changed in Portugal but, at 24 months, is in line with OECD norms.

Figure 9. Previous employment and contribution conditions for unemployment insurance, 2007-2013

Note: In some countries, eligibility depends on employment only, in others it depends on contributions, while in others still it depends on both. Not all countries express previous employment/contribution conditions in weeks, and therefore the figures presented above are approximate only. Assumptions made for the conversion to weeks include: 1 year = 12 months = 52 weeks. For Canada, the conversion from hours to weeks is done on the assumption of 36.6 hours per week (<http://well-being.esdc.gc.ca/mis-me-iowb/.3ndic.1t.4r@-eng.jsp?iid=19>). For Greece, the calculation is based assuming the condition of 125 days in the last 14 months. In the United States, another condition is the minimum earnings requirement. For Ireland, the calculation is based on 26 contributions paid in each of the two relevant tax years preceding the benefit year. For the Netherlands, the calculation is based on eligibility for the short-term benefit. In Sweden, the individual also needs to have been a member of an insurance fund in the last 12 months. In Finland, one week equals a minimum of 18 hours only. In Japan, the individual needs to have worked more than 11 days per month. For Austria, the calculation is based on the basis of the first spell of unemployment. For Chile, the calculation is for permanent contracts. In Denmark, an additional requirement is the payment of a membership fee and the work needs to have been full-time. In Turkey, the individual needs to have contributed continuously in the last 120 days. In Norway, prior work income needs to have been 24% of the average wage in the preceding calendar year, or 49% in the three preceding years.

Source: OECD Social Policies and Data, Policy Overview Tables, Unemployment Benefits.

Figure 9 also shows that a number of other countries eased access to unemployment insurance during the crisis, either by just shortening the contribution period (Canada and Finland) or by extending the reference period as well (France and Ireland). In a few countries, unemployment insurance became more difficult to access. Chile, Germany and Hungary all shortened the reference period over which contributions would be assessed (but all had relatively long reference periods to start with). The Slovak Republic and Slovenia were both countries where access to unemployment insurance was relatively stringent prior to the crisis, but they have moved in very different directions since. While the Slovak Republic shortened both the reference and the contribution periods, Slovenia did exactly the opposite.

### *The reduction in unemployment benefit generosity should help reduce the rate of long-term unemployment*

Given the well-established link between unemployment benefit generosity and unemployment duration, one would expect the reforms in Portugal to reduce the incidence of long-term unemployment. Evidence from previous unemployment benefit reforms in Portugal has shown a clear relationship between benefit generosity and work incentives. In particular, evaluations have shown that the extension of the maximum duration of unemployment benefits in 1999 prolonged unemployment spells, and also that this reform was regressive (i.e. it benefited primarily those higher up the income distribution). Further details are presented in Box 3.

#### Box 3. Unemployment benefit generosity and work incentives: Evidence from Portugal

Júlio and Ramalho (2012) and Lopes (2015) show how exit rates from unemployment in Portugal are bunched around the time of benefit exhaustion, suggesting that unemployment benefits create disincentives for job search. A number of earlier studies had produced causal evidence of the impact of maximum benefit duration on the length of unemployment spells by exploiting a reform of unemployment benefits that occurred in 1999. These findings are discussed below.

In 1999, the maximum duration of unemployment insurance benefits in Portugal depended exclusively on an individual's age at the beginning of the unemployment spell. It ranged from ten months for individuals aged under 25, to 30 months for those aged 55 or over. In July 1999, the maximum duration of unemployment insurance benefits increased for certain age groups, with a new minimum of 12 months and a new maximum of 38 months for those aged 45 and over. Table A provides more detail on the maximum benefit durations by age group, before and after the reform.

Table A. Maximum duration of unemployment insurance benefits in Portugal before and after the July 1999 reform

Months

Before the reform		After the reform	
Age group	Maximum benefit duration	Age group	Maximum benefit duration
15-24	10	15-29	12
25-29	12	30-39	18
30-34	15	40-44	24

Source: Centeno and Novo (2007).

Using a difference-in-differences methodology, Pereira (2006) assesses the impact of this reform on the length of unemployment spells. In line with the international evidence which shows that exit rates from unemployment benefits are higher in systems that are less generous, she finds that extending the duration of unemployment benefits in Portugal in 1999 prolonged unemployment spells. She finds that for those aged under 25 and aged 30-35 on the assistance benefit (*Subsídio Social de Desemprego Inicial* – SSDI), the increase in duration of entitlements increased the average days of benefit paid (up to the end of the original entitlement period) by 17.5 days. It is important to point out that this is only the “anticipation” effect of the benefit extension, and that administrative data (as used by Pereira, 2006) do not allow estimation of the impact during the extension period or beyond, which is likely to be significantly greater.

### Box 3. Unemployment benefit generosity and work incentives: Evidence from Portugal (cont.)

Centeno and Novo (2007) exploit the same reform and find that the effect on the length of unemployment spells was smaller the greater the liquidity constraints – i.e. extending the duration of unemployment benefits was regressive as it benefited primarily those higher up the income distribution. In their policy recommendations, the authors suggest that unemployment benefit duration in Portugal should be set as a decreasing function of wages prior to the unemployment spell.

Finally, Addison and Portugal (2008) exploit the differences in maximum benefit duration before the 1999 reform and compare individuals who differed by just one year of age but who were in different age groups and, therefore, had a three-month difference in their maximum benefit duration entitlement. Over the three-month periods of the unemployment spell following unemployment insurance, the transition rates into employment were 61% to 82% higher for the groups without unemployment insurance coverage.

As a concluding remark, it is worth remembering that, in addition to unemployment insurance, unemployment assistance is available in Portugal. The relevance of this to the results presented in this box is that, when individuals can move from unemployment insurance to unemployment assistance, the impact of extending the maximum duration of unemployment insurance benefits are likely to be muted.

The impact of the recent reforms is more difficult to assess. The main reason is that the most important reform (i.e. the reduction in maximum benefit duration) cannot yet be evaluated because it does not apply to individuals' first unemployment spell after the reform. It was nevertheless possible to produce some initial evidence on the reduction in benefit levels (i.e. the reduction in the cap and the declining replacement rate) (Box 4). Both the reduction in the cap and the 10% reduction in unemployment insurance after six months of unemployment appear to have increased exits from unemployment into employment for those affected – but the estimates are not statistically significant (except for the 10% reduction for individuals with low benefit levels, but then only marginally so). The evidence presented here should be seen as preliminary only, and future research should seek to replicate the analysis on larger samples and covering a longer time period after the reform.

### Box 4. Evaluating the impact of the unemployment benefit reforms

#### Reduction in maximum benefit duration

The reform which will probably have the greatest effect on the behavior of the unemployed is the reduction in maximum benefit duration. However, because workers will still be entitled to unemployment insurance under the old rules for their first unemployment spell after the reforms, it is impossible at this stage to assess the impact of this reform on unemployment duration.

#### Reduction in benefit levels

By contrast, the reductions in benefit levels (reduction in the cap and declining replacement rate after six months) have been applied to all new unemployment spells starting after April 1<sup>st</sup> 2012 and can, therefore, be evaluated. Using a 2% sample of social security records which matches individuals' contribution history to information on their benefit levels and duration, new OECD analysis presents initial evidence on the impact that these reforms have had on the probability of moving from unemployment to employment. The detailed analysis can be found in Annex D to this report. Below follows a short summary of the main results.

#### Box 4. Evaluating the impact of the unemployment benefit reforms

##### **Reduction in the cap**

To assess the impact of the new cap, a difference-in-differences model is used to compare changes in the probability of exit to employment for individuals whose benefit levels are in the range affected by the change (i.e. unemployment insurance between EUR 1 048.05 and EUR 1 257.66) to individuals whose benefit level is just below the new cap (i.e. between EUR 943.25 and EUR 1 048.05). The results indicate that the probability of exiting to employment has increased more for individuals affected by the reduction in the cap than for those who were not. However, the difference is not statistically significant. This result is confirmed in a second model where the treatment and control groups are made more similar through propensity score matching.

##### **Declining replacement rate**

To assess the impact of the declining replacement rate, a difference-in-differences model is used which compares changes in the probability of exit to employment for individuals who became unemployed in the two months prior to the introduction of the new rule (and therefore were not affected) to individuals who became unemployed in the two months after (and were affected). Once again, the treatment and control groups are made as comparable as possible through the use of propensity score matching. The results indicate that the individuals affected by the 10% reduction in unemployment insurance after six months had a greater increase in the probability of moving to employment than the individuals who were not. Again, however, the difference is not statistically significant. The only exception is for individuals on low benefits, although the coefficient is only marginally significant at the 10% level.

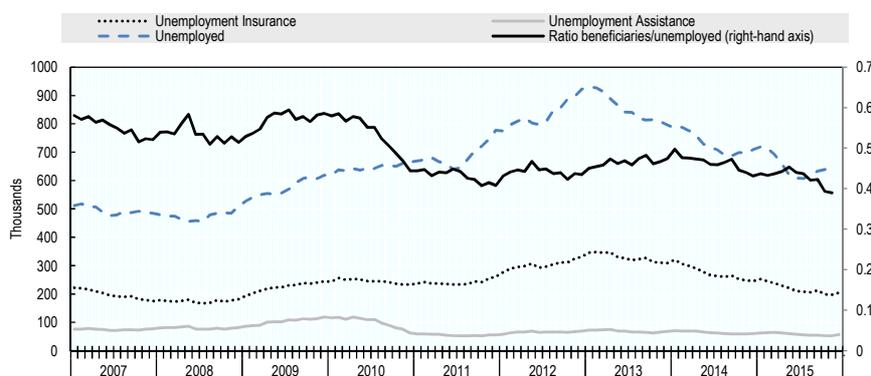

##### **Estimated savings from the reforms**

While the preliminary assessment could not detect any significant effect of the unemployment benefit level reforms on unemployment outflows, the benefit reductions will still have had an impact on the government budget. Over the period April 2012 to September 2015, it is estimated that the reduction in the cap resulted in a total saving of around EUR 70 million, while the declining replacement rate resulted in an estimated saving of around EUR 200 million. These represent an estimated 1.9% and 5.5% savings over the total amount of UI that would have been spent over this period.

#### ***Despite significant increases in unemployment between 2011 and 2013, coverage held up well***

While the number of unemployed increased by 200 000 between June 2011 and June 2013, the coverage rate (calculated as the ratio of unemployment insurance/assistance beneficiaries to the number of unemployed) rose slightly from 0.45 to 0.47 over the same period (Figure 10). This will partly reflect the easing of access to unemployment insurance in 2012. From 2014 onwards, a slight fall in the coverage rate can be observed (despite a fall in unemployment), which is likely to be related to the increase in long-term unemployment (see Chapter 2) and individuals running out of unemployment benefit (young people in particular – see Box 5). This is unlikely to reflect the new rules around unemployment benefit duration, because the grandfathering rules ensured that those would only start applying from individuals' second spell of unemployment onwards.

Figure 10. Unemployment insurance and assistance recipients and number of unemployed, January 2011 to December 2015

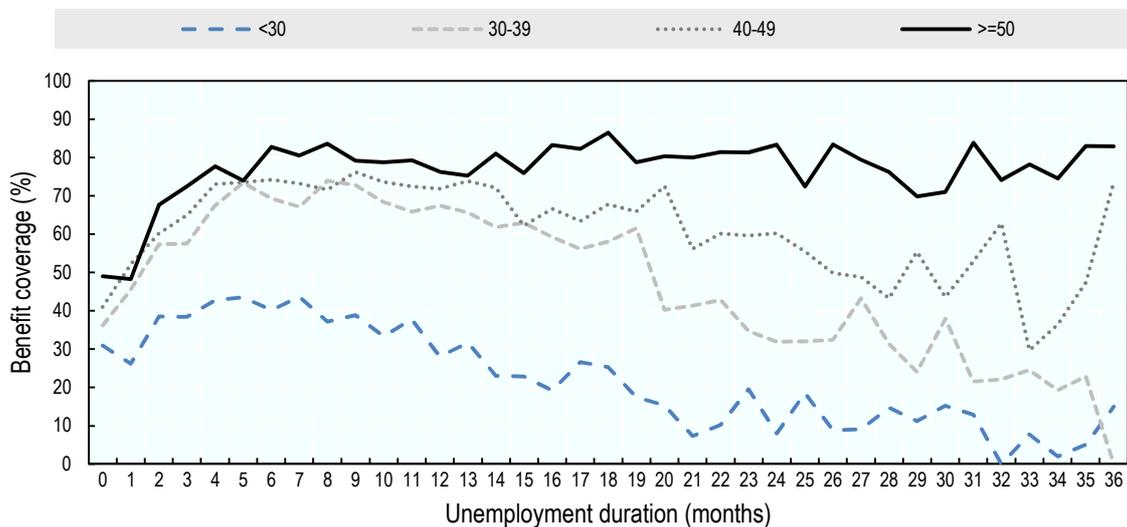

Note: Number of unemployed refers to monthly harmonised unemployment levels. Ratio of beneficiaries/unemployed is calculated as (unemployment insurance + unemployment assistance)/unemployed.

**Box 5. Unemployment benefit coverage by age and unemployment duration:  
Evidence from the Portuguese Labour Force Survey**

The Portuguese Labour Force Survey (*Inquérito ao Emprego*) contains information on whether the unemployed are in receipt of unemployment benefits (insurance or assistance). This information is less reliable than that obtained from administrative sources (and which was used for Figure 10) because it is self-reported and in particular because individuals may not be able to make a distinction between unemployment benefits and social assistance. The information is nonetheless interesting because it allows one to analyse how benefit coverage varies by age and benefit duration. This analysis, presented in the figure below, shows: i) that coverage rates are lower for youth to start with; ii) that coverage declines with benefit duration; and iii) that the decline in benefit duration is steeper the younger the age group. After three years of unemployment, for example, virtually no youth are still in receipt of unemployment benefits, while the proportion of unemployed aged 50 and over is still very high (80%) and has not declined. This graph clearly illustrates that unemployment benefits in Portugal are particularly generous (in terms of duration) for older individuals. Again, it is worth remembering that the recent reforms of maximum benefit duration will not have had much effect on these coverage rates, since they only apply from the second unemployment spell after the reforms onwards.

**Figure A. Unemployment benefit coverage by age and unemployment duration**

Note: Averages calculated over the period Q1 2011-Q3 2015. Large fluctuations are due to small sample sizes.

### Activation policies have been strengthened

Moving individuals from unemployment into jobs requires an effective activation framework, which includes the incentives contained in the unemployment benefit system discussed above, but goes beyond that to cover: other determinants of motivation, measures to promote employability, as well as policies to increase the number of opportunities available to jobseekers.

This section starts by presenting the key elements of the OECD's activation framework, and discusses Portugal's recent reforms in each of the areas defined by this framework. Portugal's eligibility criteria for unemployment benefits (i.e. the criteria determining ongoing eligibility for unemployment benefits which require recipients to actively look for work, take up suitable job offers or take part in active labour market programmes) have always been strict on paper. However, recent measures have strengthened the way these criteria are implemented in practice, with proven success in terms of exits from unemployment. Portugal has also significantly ramped up its offer of short-term training programmes and hiring subsidies for the unemployed, which international evidence has shown are particularly effective for the long-term

unemployed at times of crisis. Given that the coverage of these measures has been widened in recent years, there may now be a need to re-focus some of them (particularly the more costly ones) on those who need them most (e.g. youth and the long-term unemployed)<sup>25</sup> in order to reduce deadweight losses. Finally, a comprehensive strategy has been put in place to strengthen the Public Employment Service, which is a critical driver of the success of any activation programme. Going forward, it will be absolutely essential that this strategy is fully implemented.

### ***The OECD Activation Framework***

The core objective of activation policies is to help, support and encourage people to move into rewarding and productive jobs – with the ultimate aim of fostering more inclusive and resilient labour markets. The OECD has recently published a new framework for guiding the development of activation strategies to connect people with jobs (OECD, 2015a). This framework consists of three building blocks – motivation, employability and opportunities – which need to build on a solid foundation of well-functioning labour market institutions:

- *Motivation.* People need to be motivated to work. This involves making sure that work pays and tackling disincentives to work that may arise in unemployment and related benefits by making these benefits, where feasible, conditional on availability for work.
- *Employability.* For some individuals, a rapid return to work is unlikely, and so additional support may be required to strengthen their employability. Intensive counselling interviews can help detect opportunities to increase or update jobseekers' skills, review CVs, provide advice on job-search strategies or interview techniques, discuss referrals to active labour market policies (ALMPs) and modify individual action plans. ALMPs (like work experience or training) can, if well-designed and targeted, increase the employability of jobseekers in a cost-effective manner.
- *Opportunities.* Bringing people into employment also means expanding the set of available employment opportunities. This involves matching jobseekers with employers who are seeking to fill vacancies, and addressing demand-side barriers through actively engaging and assisting employers in hiring and retaining workers.
- *Institutions.* The successful delivery of the above three elements depends critically on the existence of strong PES institutions. The role that the PES plays in matching jobseekers and employers can be enhanced through: good performance management; partnership approaches between organisations and agencies to improve the co-ordination of service delivery; and seizing opportunities offered by digitisation and new technologies.

Over the course of the reform period, Portugal introduced changes to each of the building blocks outlined above. All these reforms are discussed in detail in the Annex A, and a short summary follows below.

### ***Motivation: Eligibility criteria for unemployment benefits (which were strict on paper) were applied more strictly in practice***

The reforms discussed in the previous section were largely intended to increase the incentives to return to work by reducing the generosity of unemployment benefits. However, another way of offsetting

---

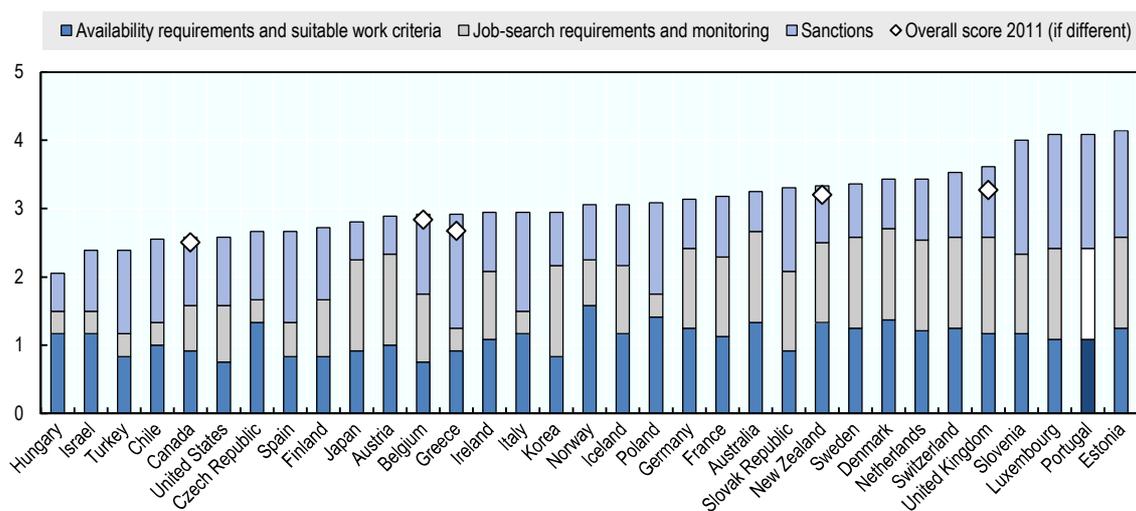

25. The evaluation literature has generally found that interventions targeted at youth tend to have smaller effects, but they are still positive, particularly in the short-run (Card, Kluve and Weber, 2015).

the negative effects of unemployment benefits on work incentives is to put in place criteria which determine the continued eligibility to receive such benefits, such as requirements that recipients actively look for work, take up suitable job offers or take part in ALMPs – with non-compliance resulting in benefit sanctions (Venn, 2012; Langenbucher, 2015). Indeed, there is growing evidence that job search monitoring and benefit sanctions can reduce the duration of unemployment and increase the rate of job entry (McVicar, 2014).<sup>26</sup>

Portugal's eligibility criteria for unemployment benefits were already among the strictest in the OECD in 2011 and its score on this indicator did not change after the recent reforms (Figure 11). Some reasons for this high score include: the requirement of fortnightly job-search interviews (which only Australia and the United Kingdom have as well) and the termination of unemployment benefits (and loss of remaining benefit entitlement) if the jobseeker refuses a suitable job offer or fails to participate in counselling interviews or ALMPs organised by the PES. A few areas where Portugal is perhaps a little less stringent than some other OECD countries include: the fact that there is no requirement to be available for work during participation in ALMPs, as well as the fact that the recipient's previous occupation, skills and/or education are considered when placing demands on occupational mobility (while in many other countries, recipients are required to accept any job that they are capable of doing, regardless of their previous occupation and the wage offered).

Figure 11. Overall strictness of eligibility criteria for unemployment insurance, 2014

Scored from 1 (least strict) to 5 (most strict)

Note: The indicator refers to the situation in mid-2014s for all countries. Availability criteria cover: availability during ALMP participation, demands on occupational mobility, demands on geographical mobility, and other valid reasons for refusing job offers. Job-searching requirements and monitoring cover: frequency of job-searching monitoring, and documentation of job-search monitoring. Sanctions cover those for: voluntary unemployment, refusing job offers, repeated refusal of job offers, refusing PES activities or ALMP placements, and refusal of PES activities or ALMP placements. For the detailed coding framework and weights applied, see Langenbucher (2015).

Source: Langenbucher (2015).

26. However, there is also some evidence that by compelling benefit recipients to take up lower paid or poorer quality jobs or jobs that do not suit their personal circumstances, strict eligibility criteria could increase the likelihood of labour force exit and reduce the quality of job matches (Venn, 2012; McVicar, 2014).

The fact that Portugal's score on the strictness of eligibility criteria has not changed does not mean, however, that nothing has improved. Indeed, one of the limitations of the OECD indicator is that it mainly reflects the strictness of rules as they are outlined in legislation or regulations, not how they operate on the ground. In the case of Portugal, for example, while jobseekers were already required to confirm their availability for work each fortnight, in practice these checks were often nothing more than an administrative requirement with very little content (Martins and Pessoa e Costa, 2014). As part of an overarching programme to modernise the Public Employment Service (*Programa de Relançamento do Serviço Público de Emprego*) new life was breathed into these job availability tests. More specifically, jobseekers aged 45 and over, as well as those who had been unemployed for six months or more, were summoned for mandatory interviews with PES case workers and referred to active labour market measures if deemed necessary. This initiative has been evaluated by Martins and Pessoa e Costa (2014) and has been found to double the monthly reemployment probability of those who had been unemployed for at least six months (see Box 6). This compulsory, bi-monthly monitoring mechanism has recently been replaced by a more personalised monitoring model, which includes quarterly action planning and ensures that different types of follow-up actions are carried out each semester (Law 34/2016 of 24 August).

**Box 6. Reemployment and substitution effects from increased activation: Evidence from times of crisis**

The *convocatórias* introduced as part of the 2012 labour market reform in Portugal required specific unemployment benefit recipients to meet jobcentre caseworkers and then participate in active labour market programmes. This initiative has recently been evaluated by Martins and Pessoa e Costa (2014) who focus on the group of unemployed who had been out of work for six months or more (and who were younger than 45). More specifically, the authors compare the outcomes of this group to those of the group of individuals with unemployment spells shorter than six months. They find that the probability of exiting from unemployment and into employment was doubled for individuals subject to the programme. As the authors point out, their results are all the more important given that the programme was implemented during a period of high unemployment. Indeed, in a situation where job vacancies are rare, one might expect the scope for displacement effects to be greater. Yet, using a different dataset in a comparative analysis across 86 job centres, they find no evidence of substitution effects such as decreased transitions to employment amongst non-eligible individuals.

Source: Martins, P.S. and S. Pessoa e Costa (2014), "Reemployment and substitution effects from increased activation: Evidence from times of crisis", *IZA Discussion Paper Series*, No. 8600.

***Employability: New training measures were introduced and participation increased significantly***

The programme to modernise the Public Employment Service also contained a host of measures to strengthen the employability of jobseekers, including: the referral of the unemployed to job search assistance or short-term training programmes within two weeks of registration; the introduction of career managers who accompany certain jobseekers on an individual and continuous basis; and more detailed and regularly updated individual action plans. Two short-duration training programmes were introduced in 2013: *formação transversal* (a 25-hours training programme aimed at improving personal, communication, and job search skills); and *Vida Ativa* (short, modular training courses, or validation of existing skills within three months of registration at the Public Employment Service). The number of participants in training measures increased significantly, from 339 824 in 2010 to 535 534 in 2014 (more than a 50% increase).<sup>27</sup> Such programmes have been associated with positive employment outcomes both in Portugal and in other countries (and particularly for the long-term unemployed and during recessions) – see Box 7 for further details.

27. These figures are taken from the IEFP's *Relatório de Execução Física e Financeira* of December of each of each year and refer to *formação profissional*.

**Box 7. The effectiveness of active labour market programmes: Existing evidence from Portugal and abroad**

Reviewing over 200 econometric evaluations of active labour market programmes (ALMPs) published since 2007, Card, Kluve and Weber (2015) reach four important conclusions about such measures: i) while they tend to have a negligible impact in the short-run, they positively affect employment outcomes after about 2-3 years; ii) programmes that focus on human capital accumulation tend to have the greatest impact; iii) ALMPs are particularly effective for the long-term unemployed; and iv) they are more likely to be effective in a recession. A key policy recommendation made by the authors is to provide “countercyclical job training programs and private employment subsidies” at times of crisis to prevent the long-term unemployed from “leaving the labor force, risking permanent losses in the productive capacity of the economy.” This is exactly what Portugal has done during the recent recession.

Evidence on the effectiveness of active labour market programmes in Portugal is much rarer, and the methodology used by most of the existing studies does not always stand up to scrutiny. It is therefore critical, going forwards, that more resources are poured into the careful monitoring and evaluation of ALMPs in Portugal.

Costa Dias and Varejão (2012) estimate that ALMPs increase the probability of employment by between 10 to 25 percentage points although – given that the authors cannot fully control for unobservable characteristics which simultaneously determine selection into the programmes and labour market success – these estimated impacts may be biased depending on the quality of the control variable data, the impact of motivational factors (particularly when participation is voluntary), and other factors. Consistent with the evidence of Card, Kluve and Weber (2015), they also find that such measures (training programmes in particular) tend to show effects only several years after participation. Nunes (2007) finds positive employment effects of subsidised internships that took place between 1998 and 2003, while Centeno, Centeno and Novo (2009) find a small reduction in unemployment duration of participation in job-search assistance programmes. The authors argue that this modest effect may be due to a lack of wage subsidies at the time when the programmes were implemented – a shortcoming which has since been addressed by the Portuguese Government.

***Opportunities: Job broking activities have been strengthened and new hiring subsidies have been introduced***

The successful activation of jobseekers depends not only on their motivation and employability, but also on the existence of sufficient demand. A key factor here is, of course, economic growth. While there is little the PES can do to promote growth, it nevertheless has a crucial role in ensuring that jobseekers have access to as wide a range of employment opportunities as possible, independently of the state of the business cycle. In particular, the PES plays a critical role in job broking – i.e. in matching jobseekers with employers who are seeking to fill vacancies. The Portuguese PES is undertaking a number of steps to strengthen its activity in this area. One of these is to set up a vacancy-registration tool, disseminated via social media, and integrated with an online vacancy database (*Portal NetEmprego*). On the employee side, the PES is trying to improve the electronic registration of the unemployed, including the possibility to upload individual action plans. There are also plans to co-operate more closely with other stakeholders (temporary work agencies, private employment agencies, employer associations, Offices for Professional Insertion – *Gabinetes de Inserção Profissional*) to better capture existing job vacancies.

While job broking is crucial for matching jobseekers and employers, some groups of jobseekers may need additional support to ensure that job opportunities are available to them. This may be the case in particular for low-skilled and/or young workers whose (expected) productivity may not exceed the minimum wage employers are required to pay for them (OECD, 2010c). For these types of workers, targeted hiring subsidies might incentivise employers to take them on, and this is an area in which Portugal has been particularly active in recent years. Two different hiring subsidies (*Estímulo 2012* and *Apoio à*

*Contratação via Reembolso da TSU*) were introduced in 2012, both revised in 2013, and eventually merged into one programme (*Estímulo Emprego*) in 2014. While these programmes have been focused primarily on youth, the low-skilled and the long-term unemployed, their coverage has changed and broadened over time (see Annex A for details). Incentives were also built in to encourage employers to offer participants permanent employment contracts (either to start off with, or as a conversion at the end of the subsidy). The subsidies awarded were relatively important in size. For example, *Estímulo 2013* covered 50-60% of the beneficiary's wage for a period of six months, and up to a maximum total value of six times the IAS (i.e.  $6 \times \text{EUR } 419.22 = \text{EUR } 2\,515$ ). As shown in Figure 12, the hiring subsidies went from no participants in 2011 to nearly 50 000 over the first ten months of 2015. While such programmes have been shown to have positive employment effects (see Box 7), they can also have significant deadweight losses (i.e. the subsidisation of workers who would have been hired anyway, even in the absence of the programme). One estimate suggests that, in the case of *Estímulo 2012*, around 60% of employers said they would have created the job even in the absence of the subsidy. Still, deadweight losses are never entirely avoidable and the loss estimated in the case of *Estímulo 2012* is actually relatively low in comparison with estimates for some other programmes from abroad (which have frequently been put at around 90%<sup>28</sup>). That being said, as the overall unemployment rate in Portugal continues on a downward trend (see Chapter 2), it may be necessary to increasingly focus the resources dedicated to such programmes on the unemployed who need them most (i.e. youth and the long-term unemployed). International evidence shows that hiring subsidies can be a very cost-effective and efficient means of reducing unemployment if they are sensibly targeted, especially on the long-term unemployed (Brown, 2015).

Figure 12. Participation in hiring subsidies and subsidised internships, 2011-2015

Note: The graph shows the cumulative number of participants in each year, by month. Participants who have not completed the programme in December of year T are carried over to year T+1.

Source: OECD analysis based on IEFP Statistics, *Síntese da Execução dos Programas e Medidas de Emprego e Formação Profissional*.

28. See Martin (2000) and Bartik (2001).

Some related measures are the subsidised internships like the *Estágios Profissionais* and the *Passaportes Emprego*, later merged under the name of *Estágios Emprego*, or also the *Contratos Emprego-Inserção* (which are work experience programmes for the long-term unemployed and RSI beneficiaries). These programmes help groups at the margins of the labour market (particularly youth and the low-skilled) gain valuable work experience, and often contain a training element. During the reform period, several changes were introduced to these programmes, often with the intention of broadening their coverage. Figure 12 shows how the number of participants in these programmes (excluding the *Contratos Emprego-Inserção*, which remained relatively stable) increased significantly from less than 20 000 in 2011 to more than 70 000 in 2014. The *Estágios Emprego* also seem to have very positive employment outcomes, with 67% of participants in work nine months after conclusion of the programme (Government of Portugal, 2014). Again, there might be a need to re-focus those programmes on those who need them most as the recovery takes hold.

New analysis carried out in the context of the present report and based on administrative data from the Public Employment Service confirms that subsidised internship programmes appear to have a positive impact on the employment outcomes of participants compared to non-participants (Box 8). The analysis further suggests that, amongst the programmes analysed, hiring subsidies have the greatest effect on the probability of employment of participants, while the effect of *Vida Ativa* and socially useful work is much more limited. However, it is important to stress that the analysis presented in Box 8 cannot control for selection into programmes based on unobservable variables which, in turn, might co-determine the outcome of interest. An important lesson to take away from this is that more research and evaluation is needed in Portugal on the effectiveness of active labour market programmes. Evidence produced by such research could help, in turn, to fine-tune the programmes concerned and to develop an ALMP portfolio which is more effective at helping the unemployed back into work. While it may be more difficult to properly evaluate existing programmes, new ALMPs should be trialled on a random, pilot basis.

**Box 8. The effectiveness of active labour market programmes in Portugal:  
New evidence based on administrative PES data**

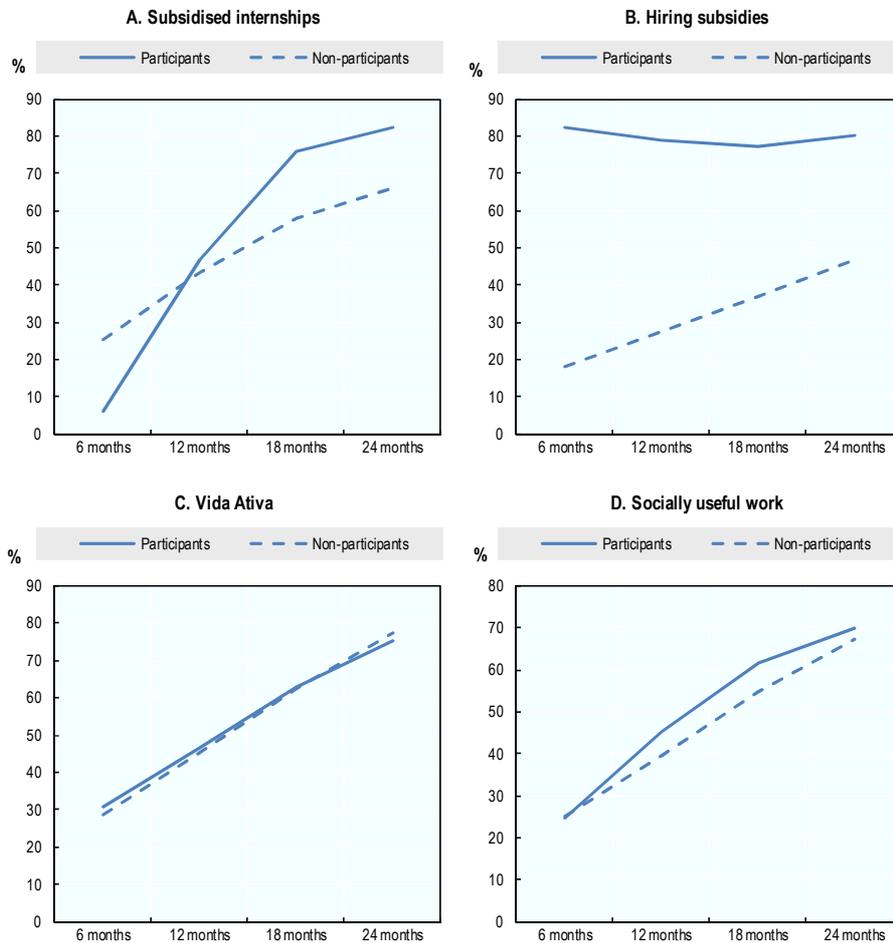

This box summarises new evidence for Portugal on the employment outcomes of participants in active labour market programmes over the period 2012-2014, based on administrative data provided by the Public Employment Service. The full analysis as well as a description of the data can be found in Annex E to this report. The analysis covers four programmes: i) subsidised internships (*Passaportes Emprego*, *Estágios Profissionais*, *Estágios Emprego*); ii) hiring subsidies (*Estímulo 2012*, *Incentivo à contratação*); iii) *Vida Ativa*; and iv) socially useful work (*Contrato Emprego-Inserção*, *Contrato Emprego-Inserção+*).

Individuals who enrolled in one of these programmes at time  $t$  are compared to a set of “control” or similar individuals who did not enroll in that programme at time  $t$ . The control group is formed using propensity score matching (PSM) techniques. More specifically, individuals are matched on the basis of age, gender, marital status, number of children, years of schooling, date of registration with the PES and previous employment history. It is important to point out that, while PSM presents a number of advantages over other techniques (like ordinary least squares), it does not allow researchers to retrieve the causal impact of a programme on employment outcomes if selection into the programme occurs on the basis of unobservable characteristics. So the findings obtained here should be interpreted in this light. Once the matching is complete, the employment outcomes of the treatment and control groups are compared at six months’ intervals:  $t+6$ ,  $t+12$ ,  $t+18$  and  $t+24$ . Because time is measured from the start of participation in a programme, it is possible that individuals may still be participating in the programme at time  $t+6$  (depending on the length of the programme). The results of this analysis are summarised in Figure A.

After six months, individuals participating in subsidised internship programmes are clearly still enrolled in the programme, however after that their employment outcomes improve significantly faster than those of non-participants (Panel A). Those who benefit from a hiring subsidy have a very high probability of being employed throughout the period – an effect which persists even after 24 months (Panel B). By contrast, *Vida Ativa* appears to have very little impact on employment outcomes (Panel C) – which may be because of the modular nature of the programme and/or the short duration of many interventions included under this programme. Finally, the employment impact of socially useful work is small and seems to disappear in the long-run (Panel D).

***Institutions: A comprehensive programme to modernise the Public Employment Service was launched***

As mentioned at the beginning of this section, the success of any activation strategy will depend critically on the strength of the institutions that are expected to implement it. In line with this, Portugal set out to improve its PES, and how it interacts with other stakeholders. A key element in this was the merging of Job Centres with Professional Training Centres to achieve a closer alignment between employment and training services offered to jobseekers. The reform also announced the introduction of stronger performance management and evaluation mechanisms: an efficiency rating system of local PES offices; customer satisfaction surveys; and regular monitoring and evaluation of placement efforts and job search activity. Efforts are also underway to modernise the PES' information systems, including: a re-design of the website; a new system for arranging interviews through e-mail and/or text messages; and breathing new life into the SAI – an interactive customer service. However, not all of these measures have been fully implemented and, going forward, it will be critical to make sure that they are.

PES performance can also be improved by introducing a greater degree of contestability and, with this in mind, Portugal relaxed the rules around the setting up of private and temporary work agencies (see Annex A for details). While the government has also announced plans to allow the PES to contract out some of its activities to private employment agencies, in practice this has still not materialised (although there are plans for two pilot projects – European Commission, 2015). It is important to point out, however, that contracting out public employment services is difficult to get right in practice, and that the evaluation literature shows mixed results. That being said, under the right contractual arrangements, private providers can improve outcomes for certain groups, bring innovation to service delivery, and introduce competitive pressure which may improve PES performance (Finn, 2011). It is particularly important to place enough weight on the quality of service provision and to have strong information systems in place which allow performance to be monitored accurately.

### **The reforms aimed to make collective bargaining more decentralised, dynamic and representative**

While collective bargaining can play an essential role in making labour markets operate more efficiently, it can also introduce important distortions when wages are pushed significantly above those that would prevail in a perfectly competitive market. This balance is difficult to get right in practice and also depends on economic and political circumstances, other labour market institutions, as well as the degree of trust between social partners – all of which help explain why the collective bargaining systems of most countries are in a constant state of flux.

Despite earlier reforms, the Portuguese collective bargaining system continued to struggle with issues of representativeness at the onset of the crisis. In particular, the combination of unrepresentative employer organisations and trade unions, on the one hand, and the practice of quasi-automatic extensions of collective agreements, on the other, led to the imposition of a large number of wage floors across the economy which, because they did not represent the circumstances of many non-signatory firms, harmed competitiveness and employment. Such wage floors can be particularly harmful during times of crisis, when a lack of wage flexibility is more likely to translate into job losses (Villanueva, 2015). In addition, extension agreements were often applied retrospectively so that firms covered by such extensions incurred large and sudden costs.<sup>29</sup>

A significant number of reforms were implemented during the crisis, all aimed at making the Portuguese collective bargaining system more representative, decentralised and dynamic. Extensions of collective agreements were temporarily frozen after Portugal received financial assistance from the Troika in May 2011 and, from November 2012 onwards, extensions were only granted if the collective agreement met certain criteria in terms of the representativeness of the employers that signed up to it. However, the initial representativeness rule (requiring the employer organisation to represent 50% of workers in the relevant sector) may have set the bar too high, ruling out extensions in the majority of cases. While the rule was later relaxed by also allowing extensions in cases where 30% of the signatory employers are small and medium enterprises, it remains to be seen what impact this will have on the share of agreements that are extended. However, given the very large share of SMEs in the Portuguese economy, it seems likely that the bar has now been set too low and that most agreements will again meet the conditions for extension without the need for significant additional effort in terms of employer organisation. As part of the package of reforms, Portugal also allowed firm-level agreements to be negotiated by works councils in firms with at least 150 employees (previously this threshold was set at 500 employees) – but the lack of worker representation in smaller firms raises questions about how much difference this will make in practice. Portugal also shortened the survival period of collective agreements that have expired and not been

29. Currently, the retroactive effects of such clauses are limited to the first day of the month in which the extension order is published, which largely solves the problem – although it may be desirable to enshrine this practice into legislation.

renewed, which should help increase the frequency with which such agreements are renegotiated. Finally, a possibility was introduced for employers to temporarily suspend a collective agreement (or certain terms contained in it) at times of crisis. While it makes sense that such action cannot be taken unilaterally by employers, the uncertainty about how cases of disagreement with worker representatives are resolved mean that this measure is unlikely to be much used in practice. It would also help if the conditions under which such clauses can be used by employers can be clarified.

Since the reforms, there has been a significant drop in the number of collective bargaining agreements and in the number of workers covered by them. While the freezing of and new rules around extensions will have played some part in this, the crisis itself will have made employers more reluctant to negotiate new wage terms. In addition, there is evidence that the decline in sector-level bargaining already started in the mid-1990s, and was accelerated by provisions contained in the 2003 Labour Code which weakened the bargaining power of unions. While the most recent data show that the number of collective agreements is rising again, it remains to be seen whether it will recover to pre-crisis levels, and also whether there will be a permanent shift towards more firm-level bargaining or not. Compared to other OECD countries, Portugal's wage bargaining system remains highly centralised and, so far, there has not yet been a strong shift towards firm-level agreements (in contrast to what has happened in Greece and Ireland, for example).

The remainder of this section discusses pre-crisis weaknesses in the Portuguese collective bargaining system, explains the reforms, and assesses their impact on the number and type of collective agreements, as well as on the bargaining coverage rate. The final part discusses the Portuguese reforms from an international perspective.

### ***Collective bargaining can make the labour market operate more efficiently***

Collective bargaining can fulfil an essential role in the efficient operation of labour markets by correcting two important market failures: i) the asymmetry of information between workers and employers; and ii) the asymmetry in bargaining power between these two groups. By addressing these market failures, collective bargaining can ensure that workers' voice is heard and that they are paid in line with their productivity – leading to a more efficient allocation of resources across firms and industries. Other efficiency gains might result from the fact that transaction costs will be lower than if bargaining was done at the individual level, and also, if markets are imperfect, from a reduction in monopsony power of the firm. In addition, collective bargaining can result in more compressed wage distributions (Addison, 2015). In particular, a combination of high union density and bargaining coverage with the centralisation/co-ordination of wage bargaining have been shown to go hand-in-hand with lower overall wage inequality (OECD, 2004). Lower wage inequality, in turn, could be beneficial for economic growth (OECD, 2015b).

However collective bargaining can also introduce distortions in the labour market. This can occur when rent-seeking behaviour pushes wages significantly above those that would prevail in a perfectly competitive market, resulting in lower employment (and possibly higher income inequality) than would otherwise be the case. In the presence of extension mechanisms, collective bargaining can also become an anticompetitive tool if a limited number of incumbent firms agree on higher wages to prevent new firms from entering the market or eliminate existing competition. The extent to which collective bargaining is distortionary rather than efficiency-enhancing will depend on number of factors, including: the flexibility of the collective bargaining system in responding to changes in economic conditions and/or the needs of individual firms, as well as the representativeness of the agreements reached. These, in turn, will depend critically on the institutional characteristics of a country's collective bargaining system.

### ***The Portuguese collective bargaining system prior to the reforms***

Prior to the reforms, it had been argued that collective bargaining in Portugal resulted in some important distortions of the labour market, introducing wage rigidity, higher unemployment, as well as lower resilience of the economy to fluctuations in the business cycle. The distortionary effect of collective

bargaining was largely blamed on a combination of unrepresentative employer organisations and trade unions, on the one hand, and the quasi-automatic extension of collective agreements, on the other.

Trade union density in Portugal is only slightly above the OECD average (20.5% versus 17.1% in 2012) and significantly below the rates observed in the Nordic countries (67.2% in Denmark, 68.6% in Finland, 82.6% in Iceland, 53.3% in Norway and 67.5% in Sweden).<sup>30</sup> At the same time employer representation is weak. Estimates based on administrative data (*Quadros de Pessoal*) suggest that, on average, employer organisations in Portugal represent just 38% of workers.<sup>31</sup> Moreover, as Table 1 makes clear, such representation varies significantly by industry, from as little as 9% in the water sector to over three quarters in the financial and insurance sector.<sup>32</sup>

Despite low trade union and employer representation, collective agreements in Portugal covered around 90% of workers prior to the crisis (Addison, Portugal and Vilares, 2015), which can be explained by the fact that collective agreements were extended almost automatically by the government to the entire sector, upon simple request of one of the parties to the agreement.<sup>33,34</sup> This led to a situation where wage agreements reached between a minority of firms and workers (often men with permanent contracts and high job tenure, working for large employers or firms shielded from competition – Portugal and Vilares, 2013; Vilares, 2015) would be extended to all other firms and workers in the sector.

Because these agreements set wages at a very detailed level (both by industry and by occupation), the collective bargaining system in Portugal effectively imposed as many as 30 000 wage floors across the country each year (Martins, 2014) – which are believed to have had negative consequences in terms of firms' competitiveness, employment as well as labour market segmentation (see Box 9). To make matters worse, when collective agreements were extended, the corresponding wage clauses often applied retrospectively, forcing employers affected to pay the resulting wage arrears. This exacerbated the potential negative effects of administrative extensions on competitiveness and employment (Cardoso and Portugal, 2005; Martins, 2014).

---

30. These figures are taken from OECD and J. Visser, ICTWSS database, version 3.0. Note that this rate includes the public sector where density is believed to be much higher than in the private sector. Estimates by Addison, Portugal and Vilares (2015) based on the *Relatório Único* put the union density rate in Portugal at a much lower figure: 11% on average over the period 2010-2012. This estimate is based on a question which asks the employer to “Indicate the number of workers for whom you have knowledge of their membership in a union (because they are union officials, because you deduct membership dues from their salary, or because the worker informed you about his/her membership so as to determine which particular collective regulation is applicable to their case).” However, given that there is no legal obligation in Portugal to disclose union membership, the figures reported by employers in the *Relatório Único* are likely to be an underestimate.

31. These estimates are consistent with those obtained elsewhere. The 2006 *Livro Verde sobre as Relações Laborais* (MTSS, 2006) already pointed out that a large proportion of employers are not affiliated to any employer organisation, and the 2007 *Livro Branco das Relações Laborais* (MTSS, 2007) found that there was no worker representation of any kind in two thirds of Portuguese workplaces.

32. It is important to point out that some important groups will never be represented by collective agreements: the unemployed and potential start-ups.

33. Voluntary extensions by the employers to non-unionised members are also very common because there is no legal requirement for trade unions to reveal their constituency. Employers are therefore faced with the practical impossibility of distinguishing between workers who are union members (and for whom the agreement is binding) and those who are not.

34. Another reason for the high level of coverage is that agreements tended to remain valid for a relatively long period of time.

Combined with the facts that: i) firms are legally prohibited from reducing base wages (unless this is permitted by collective agreement)<sup>35</sup> and ii) collective bargaining agreements in Portugal can sometimes be difficult to re-negotiate, this system resulted in a high level of downward wage rigidity in the Portuguese labour market, which is particularly harmful at times of crisis with low inflation: if firms cannot adapt to worsening economic conditions by lowering (real) wages, the only other adjustment channel left is employment.<sup>36</sup> During the recent crisis, this is indeed what has been observed: large numbers of workers had their wages frozen (see Box 14 in Chapter 2), but low inflation meant real wages moved little and large employment losses ensued (Carneiro, Portugal and Varejão, 2014).

**Box 9. There is evidence that quasi-automatic administrative extensions of collective bargaining agreements in Portugal have harmed competitiveness and employment**

Research has shown that the quasi-automatic extension of collective agreements in Portugal has had negative effects in terms of employment (including the quality of employment), as well as firm survival.

Guimarães, Martins and Portugal (2014) tentatively use the term “upward nominal wage rigidity” to refer to the consequences of the Portuguese collective bargaining system which obliges firms to increase the wages of their workforce in order to comply with the administrative extensions of collective agreements. Using the potential increase in a firm’s wage bill (measured as the difference between workers’ current wages and those implied by the new wage floors), the authors find that, over the period 1986-2009, firms more heavily affected by changes in wage floors decreased their hiring rates and, more importantly, significantly increased their separation rates: a 10% increase in the wage bill led to a fall in employment of 2.1%, which is largely driven by an increase in separation rates (which increased by 2.3 percentage points in response to a 10% increase in the wage bill). The authors also find that a 10% increase in the (real) wage bill increased the probability of firm closure by 7.8 percentage points.

Looking at what happens following an extension of a collective bargaining agreement in a particular sector, Martins (2014) finds that employment decreases by 2% four months after the extension is issued, resulting from both a fall in hiring and an increase in firm closures (but no significant change in separations or firm start-ups is observed). In addition, Martins finds that such administrative extensions (which also entail the payment of substantial wage arrears) tend to increase the share of dependent self-employment (and therefore labour market segmentation) as firms seek to reduce their costs. The author also finds that small firms are more negatively affected by such extensions.

Building on this work, Hijzen and Martins (2016) analyse what happened when Portugal suspended the extensions of collective bargaining agreements in mid-2011. Their work suggests that extensions had a negative impact on employment growth, concentrated amongst non-affiliated firms. The authors further argue that the lack of representativeness and the retro-activity of extensions are key drivers behind this negative employment effect – particularly in the context of a recession.

The evidence found for Portugal is consistent with the international evidence on extensions of collective wage agreements (Villanueva, 2015): while extensions can be useful tools to reduce wage inequality and gender gaps, there is a risk that they come at the cost of employment losses, particularly during recessions. Any income gains made by workers covered by extensions therefore need to be weighed against the income losses incurred by those who lose their job.

Portugal (2014), “Upward nominal wage rigidity”, paper presented at the Deutsche Bundesbank/Institute for Employment Research conference on “(European) Labour markets and the economic crisis” held on 12/13 June 2014 in Eltville, Germany; Martins, P.S. (2014), “30,000 minimum wages: The economic benefits of collective bargaining extensions”, *IZA Discussion Paper Series*, No. 8540. Villanueva, E. (2015), “Employment and wage effects of extending collective bargaining agreements”, *IZA World of Labor*, No. 136.

35. See Article 129 of the Labour Code: “É proibido ao empregador diminuir a retribuição, salvo nos casos previstos neste Código ou em instrumento de regulamentação colectiva de trabalho.”

36. Cardoso and Portugal (2005) had shown that the contractual wages set by collective agreements set a floor to remuneration and that actual wages frequently exceed those minima, giving rise to a “wage cushion”. This wage cushion gives firms some flexibility to adjust real wages downwards at times of crisis – however this mechanism only really works if inflation is positive.

Table 1. **Employer organisations' membership and density, 2010-2014**

Percentage of companies member of employer organisations, and percentage of workers employed by member companies of employer organisations (average 2010-2014)

Industry	% employers member of employer organisation	% members that are SMEs	% of workers covered by employers that are member of an employer organisation
A Agriculture, forestry and fishing	8.8	99.9	13.9

### ***Reforms of the Portuguese collective bargaining system***

The recent labour market reforms introduced a number of changes to collective bargaining in Portugal in an attempt to make it more:

1. *Representative*. After a freezing of administrative extensions from May 2011 onwards, criteria were introduced towards the end of 2012 for approving future extensions of collective agreements. The reasoning behind such representativeness criteria is to limit the potential negative effects of extensions on the competitive position of non-affiliated firms. Ideally, such criteria should be challenging enough (so that they work as an incentive for employers to organise), but not too challenging (so as to make extensions virtually impossible). The first representativeness rule introduced in Portugal stated that extensions would only be granted if the employers who signed the agreement employed at least 50% of the workers in the sector, geographical area or occupation to which the agreement was to be extended. However, given the low employer organisation density rate in Portugal (see Table 1), this condition more or less ruled out most extensions and was probably too demanding. Part of the problem is that a very large proportion of employers in Portugal are SME's (with fewer than 250 employees) and that these are difficult to organise. Acknowledging this economic reality, the government subsequently introduced an additional rule

allowing extensions in cases where the signatories to the agreement consist of at least 30% of micro-, small- and medium-sized enterprises. While it remains to be seen what effect this new rule has, one would largely expect a return to the pre-crisis situation given that 99.7% of firms in Portugal are SMEs. Indeed, data on employer organisation membership in 2012 suggests that, on average, 60% of the members of employer organisations in Portugal were SMEs, and that only 23 out of 410 employer organisations had fewer than 30% SME members.

2. *Decentralised.* The second change to the collective bargaining process was to allow works councils in firms with at least 150 employees to negotiate agreements at plant level (previously, as part of the 2009 revision of the Labour Code, the threshold had been set at 500 employees). In theory, this would allow negotiated wages and working time arrangements to more closely reflect a firm's economic reality.<sup>37</sup> Some commentators have argued that this will not make much difference in practice, given that the Portuguese Constitution grants trade unions exclusive rights to negotiate on behalf of workers (Article 56) and that works councils will therefore only be allowed to conduct such negotiations if the necessary powers are delegated to them by unions.<sup>38</sup> However, such rules are common throughout the OECD (except in Greece and Romania) and exist because company-based worker representation is never truly independent of the employer. For example, under existing laws, works councils cannot call a strike, which significantly reduces their bargaining power. Even in Germany, where there has been a clear shift towards company-level bargaining, legislation formally prohibits works councils from concluding firm-level agreements on issues covered by collective bargaining unless they are expressly authorised to do so by the relevant sector agreement (Addison et al., 2014). A more important problem in the case of Portugal is that worker representation in small firms is very poor (Visser, 2016).<sup>39</sup> Estimates based on the European Company Survey suggest that only around 8% of establishments in Portugal with 10-249 employees had some form of workplace representation in 2013, compared to 40% on average in the other countries that participated in the survey (Figure 13).<sup>40</sup>
3. *Dynamic.* The third change aimed to encourage more frequent and swifter re-negotiations of collective agreements by placing additional constraints on the time for which they remain valid. On the one hand, the reforms targeted cessation clauses contained within certain older collective agreements which stipulated that the agreement would remain in force until it was replaced by a

---

37. The reforms also further encouraged the inclusion of articulation clauses between different levels of bargaining, particularly on matters of functional and geographical mobility, the organisation of working time, and compensation.

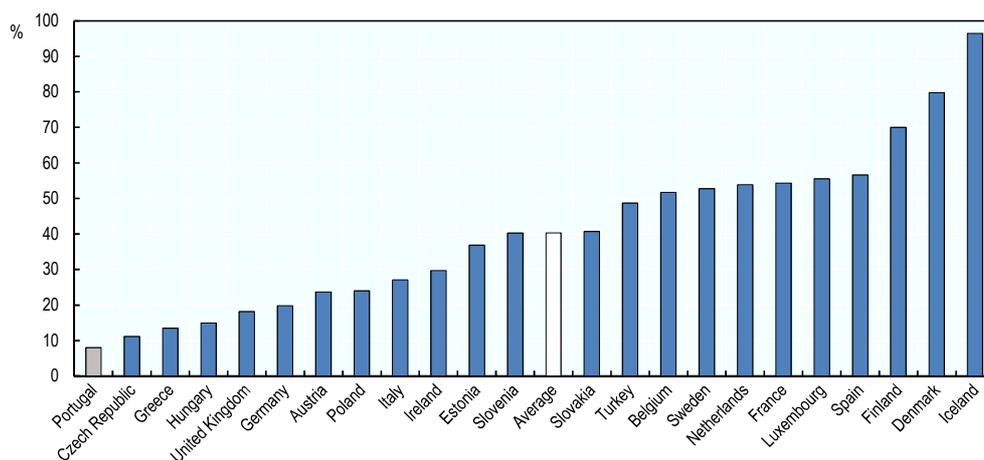

38. Reform proposals favouring agreements that can be signed independently of the trade union had to be abandoned in the face of strong union opposition (Addison, Portugal and Vilares, 2015). That being said, even before the reforms, there were some atypical collective agreements signed at plant level between employers and their works councils that have proved successful over the years (Palma Ramalho, 2013). However, such agreements, where they were signed without the mandate of the relevant union, would not be legally enforceable (Távora and González, 2015).

39. Because smaller firms have no (or little) union representation in Portugal, the lowering of the threshold in 2012 to allow agreements in smaller firms to derogate from higher-level agreements could be argued to have increased the level of disarticulation of the system. As pointed out by Visser (2013), however, "Articulated bargaining is rare. Most countries are either stuck with a more centralised solution, usually because there is no enterprise-level representation that has the trust of the unions and capability to confront management in bargaining, or local bargaining proceeds without strong checks and balances."

40. Visser (2013) mentions the interesting case of Hungary where the exclusive right of unions to negotiate collective agreements was removed at the turn of the millennium and a legal provision was introduced to allow works councils to sign collective agreements in the absence of union organisation in the workplace. However, this measure was not effective because, despite being mandatory, effective works councils existed only where unions were present. The provision was repealed again in 2002.

new one. The validity of such cessation clauses was reduced from five to three years.<sup>41</sup> In addition, a cap of 18 months was placed on the grace period (*sobrevigência*) which kicks in when one of the parties withdraws from an agreement and which allows for negotiations to take place (there was no cap prior to the reforms). Finally, the additional grace period (*ultra sobrevigência*) for which the agreement remains valid if negotiations turn out to be unsuccessful was reduced from 60 to 45 days.

Figure 13. **Proportion of establishments with 10-249 employees that have some sort of worker representation, 2013**

Source: OECD analysis based on the European Company Survey.

In addition to the reforms outlined above, employers can (since September 2014) temporarily suspend a collective agreement at times of crisis (i.e. for reasons of “hardship” or “inability-to-pay”) as long as: i) this can be shown to be necessary for the preservation of jobs; and ii) the necessary agreement has been obtained from the relevant trade union(s). While such a safeguard makes sense to protect workers from potential abuse by employers, it is not clear what would happen in the case of disagreement between unions and employers – which makes the measure difficult to implement in practice and, therefore, reduces its potential effectiveness.<sup>42</sup> It would also help if the conditions under which employers can suspend a collective agreement could be clarified. In Spain, for example, sectoral agreements have to include objective conditions (such as a fall in sales or productivity over a specified period of time) that specify when firms may opt out of what was agreed.

41. There was also a suggestion to further reduce the validity of such cessation clauses to two years, but it is not clear that this would make much difference in practice. Based on an analysis of agreements that have already been denounced, Naumann (2014) concluded that the length of the survival period of agreements with cessation clauses would be of little practical relevance because: i) very few of these had a cessation clause; and ii) the last revision of these agreements dated back to more than 15 years, making the survival period irrelevant.

42. It has been argued that a major stumbling block to the use of such opt-out clauses is that works councils need explicit agreement from the union to negotiate agreements at the firm level. While this is probably true, there is a strong argument for maintaining such union consent, which is that works councils are never truly independent from their employers and therefore have much weaker bargaining power (especially since they are usually not legally entitled to call a strike).

### Impact of the collective bargaining reforms

*The number of sector agreements has dropped, but not only because of the reforms*

Since the reforms, there has been a significant drop in the number of sector agreements as well as in the number of extensions of these agreements – although the latest data show some recovery. The number of sector agreements fell from 142 in 2010 to just 27 in 2013, but was back up again to 65 in 2015 (Table 2). Similarly, the number of extensions fell from 128 in 2010 to 9 in 2013, but stood at 44 in 2015. More significantly, the ratio of extensions to sector agreements had fallen markedly (from around 100% prior to the reform to just over a quarter in 2011) but, in 2015, increased again to 68%.

Table 2. Evolution of collective agreements and extensions, 2008-2015

Year	Number of agreements <sup>a</sup>				Workers covered				Extensions (of sector agreements)	
	Total	Sector	Groups of firms	Firm level	Total	Sector agreements	Agreements between groups of firms	Firm-level agreements	Number	% <sup>b</sup>
2007	251	160	27	64	1 430 660	1 430 660	58 233	32 384		
2008	296	172	27	97	1 894 846	1 778 216	47 232	69 398	178	103%
2009	251	142	22	87	1 487 193	1 299 371	59 902	37 952	128	90%
2010	230	141	25	64	1 485 950	1 309 267	64 455	33 344	149	106%
2011	170	93	22	55	1 242 181	1 160 080	52 737	24 102	24	26%
2012	85	36	10	39	404 756	291 068	26 645	9 909	13	36%
2013	94	27	18	49	241 539	197 017	27 104	17 418	9	33%
2014	152	49	23	80	246 643	214 603	19 596	12 444	16	33%
2015	138	65	20	53	568 875	446 025	21 728	22 624	44	68%

a. Sector agreements (*Contratos Coletivos de Trabalho*, CCT) are agreements negotiated between one or more employer organisations and one or more trade unions. Agreements between groups of firms (*Acordos Coletivos de Trabalho* – ACT) are signed by several employers that are not part of an employer organisation and one or more trade unions. Firm-level agreements (*Acordos de Empresa*) involve just a single employer.

b. The percentage of agreements that are extended may exceed 100% because the numerator measures the number of extensions that were granted in a specific year, while the denominator measures the number of agreements signed in that year.

Source: MSESS/DGERT.

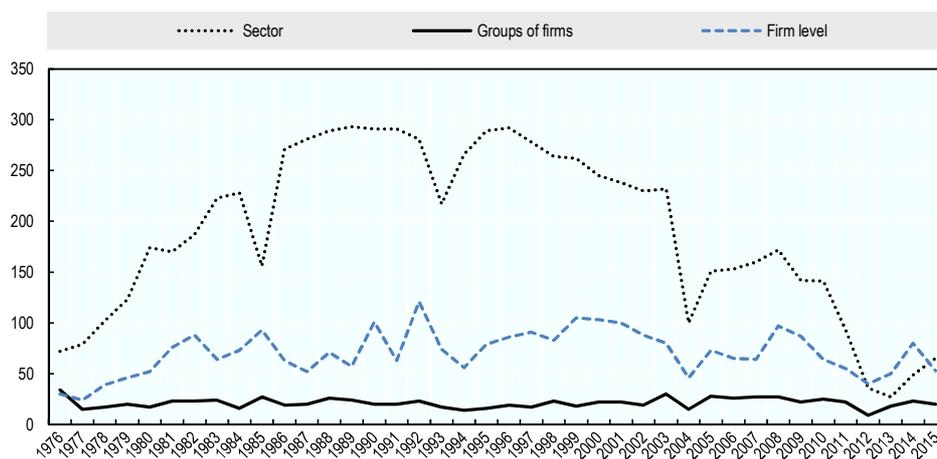

There is some disagreement as to why the number of sector agreements has fallen so drastically, although the reasons advanced are not mutually exclusive. Some commentators contend that, as a result of the reforms, employers have been reluctant to sign agreements which are unlikely to be extended to other firms in the sector because this would put them at a competitive disadvantage (Campos Lima, 2013; ILO, 2014). This would also help explain why there has been an increase in agreements in 2014, following the softening of the rules around the extension of agreements towards the middle of that year. An alternative interpretation is that these trends are simply a consequence of the crisis and the attempt by employers to reduce costs by freezing nominal wages (Addison, Portugal and Vilares, 2015). Indeed, the number of sector agreements also fell in a number of other countries as a result of the crisis (e.g. Belgium, the Czech Republic, France, Germany, Italy, the Netherlands, Slovenia, Spain – Visser, 2016). Yet another explanation traces the origins of the decline in sector bargaining back to the 2003 Labour Code, which introduced the possibility of expiry of collective agreements and also eliminated the principle that collective agreements could only establish more favourable conditions than those set by the general law (Távora and González, 2015).<sup>43</sup> According to this line of argument, the 2003 Labour Code significantly weakened the bargaining power of unions<sup>44</sup> which

43. The 2009 Labour Code subsequently specified a number of areas that could not be object of less favourable dispositions in collective agreements (Távora and González, 2015).

44. The 2003 Labour Code allowed employers to withdraw unilaterally from existing agreements (whereas previously, existing agreements could only be cancelled if all signatories agreed). More specifically, the 2003

translated into a low level of renewals of collective bargaining agreements during the crisis. Indeed, as Alves, Poças and Tomé (2013) show, there was a drastic fall in the number of sector agreements in 2003 (Figure 14). That being said, the same figure also shows that the number of sector agreements was already on a longer-term (albeit gradual) path of decline that started in the mid-1990s – well before the recent labour market reforms as well as the economic and financial crisis.

Figure 14. Evolution in collective bargaining, by type of agreement, 1976-2015, Portugal

Source: MSES/DGERT and Alves, Poças and Tomé (2013).

Going back to Table 2, the data also show that there has been a fall in agreements between groups of firms (*Acordos Coletivos de Trabalho*)<sup>45</sup> from 27 in 2007 to 10 in 2012, but that their number has been increasing again in recent years (23 in 2014 and 20 in 2015). Perhaps more interesting given the reforms that have taken place, the number of firm-level agreements has also fallen, from 97 in 2008 to 39 in 2012. However, their number increased to 80 in 2014 and their share of the overall number of agreements has risen from one third in 2008 to over half in 2014. However, it would be too soon to conclude that collective bargaining in Portugal is now more decentralised than it was before the crisis – especially since there was a fall again in the number of such agreements to 53 in 2015 (with their share down to 38%).<sup>46</sup> Indeed, as the next section will show, collective bargaining in Portugal generally remains very centralised.<sup>46</sup>

Labour Code specified that, following a period of unsuccessful negotiations, any party could denounce the agreement, thereby initiating a process which would culminate in its expiry (*caducidade*) if a new agreement could not be reached. One loophole left by this legislation was that agreements with a “cessation” clause (i.e. a clause which stipulates that the agreement remains in force until replaced) could still not expire. These cessation clauses were targeted by the 2009 Labour Code, which prohibited them in new agreements and put a limit on their validity in existing agreements.

45. These are agreements signed between several employers that are not part of an employers’ organisation and one or more trade unions. Such agreements are common in the financial and utilities sectors (Addison, Portugal and Vilares, 2015).
46. An alternative firm-level union strategy outside formal bargaining (the *caderno reivindicativo*) has gained importance during the crisis as collective bargaining blockages appeared at the sector level (Távora and González, 2015): “The *caderno reivindicativo* simply consists of local trade unions meeting with the workers of a firm and on their behalf approaching their employer without any formalities with the purpose of negotiating wage increases (and in some cases other terms of employment).”

*Collective bargaining coverage has fallen, but there is disagreement about how much*

There is also some disagreement as to how important the fall in collective bargaining coverage has been.<sup>47</sup> According to Addison, Portugal and Vilares (2015), the stock of workers covered by collective agreements has fallen only marginally in recent years, and still stood at 89% in 2012, primarily because many remain covered by old agreements that are still valid. Similarly, the 2014 *Quadros de Pessoal* data registers a coverage rate of 89%. However, Visser (2015) estimates that the coverage rate has fallen more drastically, from 84.9% in 2007 to 72.2% in 2013.<sup>48</sup> Visser argues that even these estimates may not be very meaningful because the wage floors fixed in older agreements may mean very little in practice as they are likely to have been overtaken by the national minimum wage. In addition, if there is no uptake in the number of new agreements very soon, then rules around the expiry of collective agreements mean that the coverage rate may fall sharply in years to come. To put things into context, however, the fall in collective bargaining coverage in Portugal is not unique and follows a more general trend observed across the OECD (Box 10).

**Box 10. The impact of the crisis on collective bargaining coverage in OECD countries**

According to the estimates by Visser (2015), the average collective bargaining coverage rate across OECD countries has declined from 53.5% prior to the crisis to 49.4% in 2013 (Figure A). While in most countries the fall in the coverage rate was relatively minor and part of a longer-term trend, a few countries have seen significant reductions in the collective bargaining coverage rate over the last few years, including: Greece (a fall of nearly 50%), Hungary and the Slovak Republic (-38%), Slovenia (-29%) and Portugal (-14%). All of these countries have pushed through significant reforms of their collective bargaining system during this period. At the same time, the figure shows that very large differences persist across OECD countries in the collective bargaining coverage rate – with nearly universal coverage in countries like Finland, Belgium, Austria and France, and rates below 20% in many of the non-European OECD countries. Despite the falls in recent years, bargaining coverage in Portugal remains significantly above the OECD average.

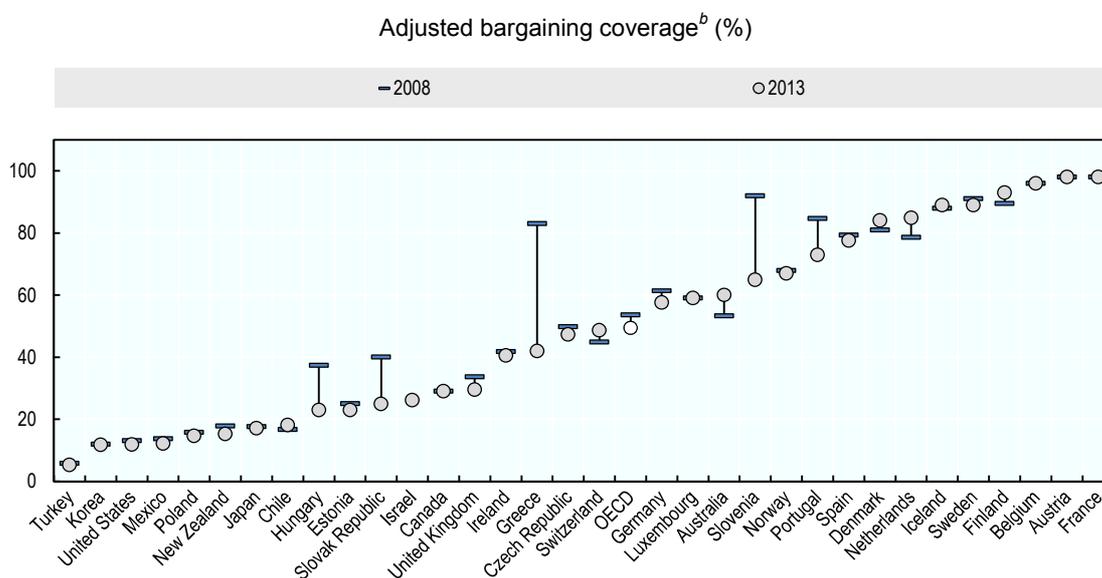

In many countries (including Portugal) low unionisation co-exists with high bargaining coverage because collective agreements are extended to the entire sector, occupation or geographical area. However, Visser (2013) argues that extending collective bargaining agreements is not the only way of obtaining high levels of bargaining coverage. In some countries (like in Scandinavia) a high bargaining coverage rate is achieved through a high level of unionisation – although this may depend on some unique features, such as union involvement in the running of unemployment insurance benefits, and/or the right to organise solidarity strikes. For example, in Denmark and Sweden, unorganised firms frequently sign “adhesion agreements” under strike pressure from unions (Visser, 2016).

Visser (2013) also argues that the key to a high bargaining coverage rate is multi-employer bargaining: for 25 European countries over the period 2000-2009 there is a strong correlation ( $r=0.8$ ) between the level of employer organisation and the bargaining coverage rate. Visser (2013) provides convincing evidence that, wherever multi-employer bargaining has been replaced by single-employer bargaining, the coverage rate has fallen significantly (e.g. Britain in the 1980s; New Zealand and Australia in the 1990s). Similarly, Visser (2016) points out that some of the greatest losses in bargaining coverage in recent years occurred in countries where important regulatory changes happened that led to a reduction in multi-employer bargaining.

(2015), ICTWSS Database, Version 5.0, Amsterdam Institute for Advanced Labour Studies AIAS; Visser, J. (2013), “Wage bargaining institutions – From crisis to crisis”, *Economic Papers*, No. 488, European Commission Directorate-General for Economic and Financial Affairs.

47. Bargaining coverage gives an indication of the extent to which workers’ wages are set by collective agreement rather than by market forces (Pedersini, 2015).
48. The level difference in Visser’s (2015) coverage rates is due mainly because of his choice of denominator, which also includes public sector workers (who are not covered by collective agreements).

## Box 10. The impact of the crisis on collective bargaining coverage in OECD countries (cont.)

Figure A. Changes in collective bargaining coverage, 2008-2013<sup>a</sup>

- a. 2005 instead of 2008 for Ireland. 2007 instead of 2008 for Denmark, Estonia, Hungary, New Zealand, Sweden and Switzerland. 2009 instead of 2008 for Chile and Norway. 2011 instead of 2008 for Mexico. 2009 instead of 2013 for Ireland. 2011 instead of 2013 for New Zealand. 2012 instead of 2013 for Australia, Estonia, France, Israel, Korea, Luxembourg, Poland and the United States.
- b. Adjusted bargaining coverage = employees covered by collective (wage) bargaining agreements as a proportion of all wage and salary earners in employment with the right to bargaining, expressed as percentage, adjusted for the possibility that some sectors or occupations are excluded from the right to bargain (removing such groups from the employment count before dividing the number of covered employees over the total number of dependent workers in employment).

*There has been an important fall in the number of workers receiving contractual wage increases*

The fall in collective agreements and extensions led to a significant fall in the number of workers receiving pay rises as a result of such agreements: from 1.7 million in 2008 to less than 200 000 in 2013 (Table 3). Even among the workers benefiting from pay rises, however, those were often small and, in 2011 and 2012, not sufficient to beat inflation (i.e. wages declined in real terms). In Chapter 2 of this report, these wage developments (and their impact on Portugal's competitiveness) will be analysed in further detail.

Table 3. Annual changes in contractual wages, 2008-2015

	2008	2009	2010	2011	2012	2013	2014	2015

### *The Portuguese collective bargaining reforms from an international perspective*

Reforms of collective bargaining institutions of the type implemented in Portugal over the past few years are not unique, and similar changes have been introduced in other countries at the same time (e.g. in Greece, Spain, Ireland). While many of the reforms in those countries were quite substantial and often carried out under pressure from international finance institutions, they frequently resulted in a mere catch-up process with other countries where similar changes had already occurred, albeit more gradually and over a longer period of time (Eurofound, 2015). In particular, one can observe a general, longer-term trend across OECD countries in terms of: the decentralisation of collective bargaining; a reduction in the use of administrative extensions; and limits placed on the time validity of agreements. The need for such changes has been attributed to globalisation and increased competition from abroad, which mean that individual firms need more flexibility to adjust labour costs and productivity in order to respond to changes in market conditions.<sup>49</sup> Moreover, many commentators agree that such trends are likely to continue for the foreseeable future (Visser, 2013; Eurofound, 2015). While this sub-section argues that the recent reforms in Portugal followed a more general trend across OECD countries, the analysis will also show that, compared to many other countries, Portugal's wage bargaining system remains highly centralised and that there has not yet been a strong shift towards firm-level agreements (in contrast to what happened in Greece and Ireland, for example).

#### *Decentralisation*

Visser (2015) constructs a summary measure of the extent of decentralisation of collective bargaining which considers simultaneously: the predominant level at which bargaining takes place;<sup>50</sup> the frequency or scope of additional enterprise bargaining; the possibility of opening clauses in collective agreements; the extent of articulation of enterprise bargaining; and the possibility of derogation.<sup>51</sup> The evolution of this indicator over time is shown in Figure 15, which shows that there has been a clear trend across the OECD towards decentralisation.<sup>52</sup> In most countries, this had been happening well before the recent economic and financial crisis, but in Greece, Portugal and Spain the changes are more recent.

While the indicator suggests that Portugal's collective bargaining system has become more decentralised, the main driver of this change is the 2009 change to the Labour Code which introduced the possibility of firm-level agreements. However, as argued above, there has not (yet) been a strong shift towards firm-level agreements in Portugal – a finding which is confirmed in Figures 16 and 17, which show that the dominant level of bargaining in Portugal remains the sectoral level, while additional enterprise bargaining on wages is still rare, even in large firms. The experience in Portugal during the recent crisis stands in stark contrast to what happened in Greece and Ireland, where multi-employer bargaining “all but disappeared” during the recession (Figure 16 and Visser, 2016). Even amongst

49. One argument for multi-employer bargaining has been that, by establishing a wage floor across all employers in the same sector, it takes wages out of the equation as far as competition is concerned. However, with increasing competition from abroad, this argument loses a lot of its strength.

50. A particular level is dominant if it accounts for at least two-thirds of bargaining in terms of employees covered.

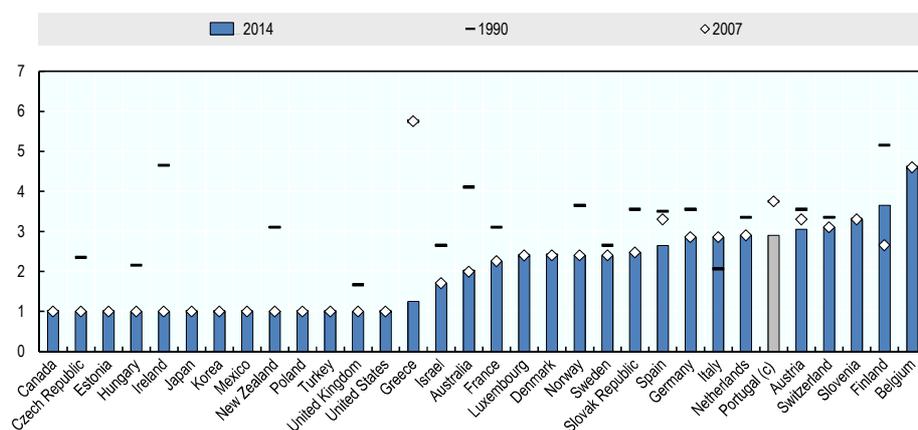

51. Visser (2015) defines derogation as “the possibility of setting aside the favourability principle in higher-order (usually sector) agreements, allowing deviation from norms established in the higher-order agreement that in some aspects are less favourable, possibly in exchange for some other guarantees or benefits.”

52. The trend towards increased decentralisation has often been based on the argument that decentralised collective bargaining systems achieve better macroeconomic outcomes that are closer aligned to those that would have been achieved through market forces. However, it has also been argued that similar macroeconomic outcomes can be achieved by highly centralised bargaining systems, as long as there is a high level of co-ordination and a responsible attitude on the part of unions (Pedersini, 2015). In particular, highly centralised wage bargaining institutions need to concentrate on objectives that are in the interest of as many of their members as possible and can, therefore, “promote low structural unemployment and mitigate the direct impact of shocks on employment” (OECD, 2014a).

countries where sector bargaining remained the dominant level, there has been a move to more frequent bargaining at the firm level. In Austria, for example, employers in the metal-engineering industry left the joint bargaining platform in 2012 and signed separate agreements (Visser, 2016).

Figure 15. Centralisation of wage bargaining, 1990-2014<sup>a</sup>

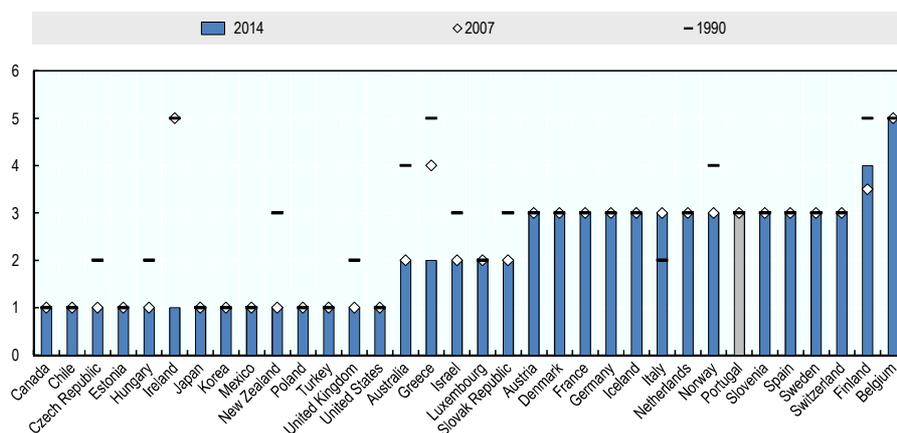

Index of centralisation of wage bargaining<sup>b</sup>

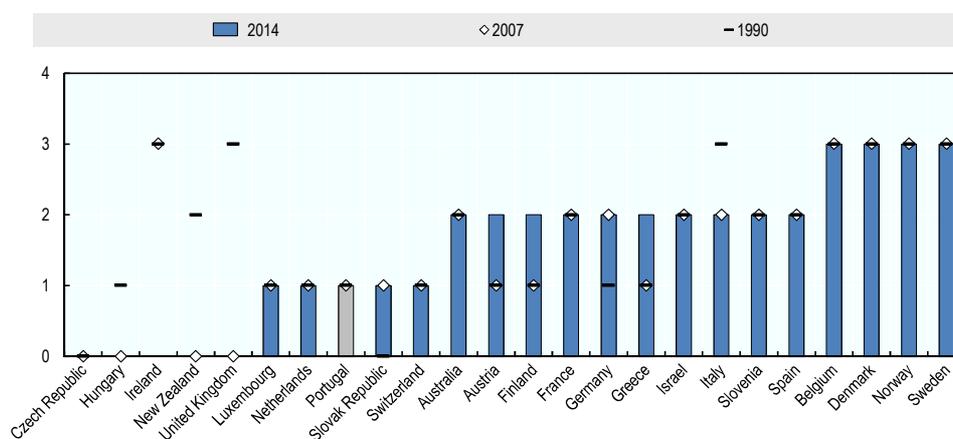

- 1991 instead of 1990 for the Czech Republic, Estonia and Portugal. 1993 instead of 1990 for the Slovak Republic.
- The index is calculated as:  $LEVEL - (fAEB + OCG) / 4 (= \text{max value}) + (Art + DR - 1) / 5 (= \text{max value})$ . Where: LEVEL = the predominant level at which wage bargaining takes place; fAEB = frequency or scope of additional enterprise bargaining; OCG = general opening clauses in collective agreements; Art = articulation of enterprise bargaining; DR = derogation. For further detail on how these variables are defined, see Visser (2015).
- The 2014 estimate for Portugal differs slightly from that in Visser (2015) because, following discussions with the author, "derogation" has been coded as 2 (i.e. favourability principle is anchored in law, derogation possible under conditions) instead of 0 (i.e. favourability is inversed, enterprise agreements favoured over higher-order agreements).

Figure 17. Frequency or scope of additional enterprise bargaining<sup>a</sup>, 1990-2014<sup>b</sup>

- a. 3 = additional enterprise bargaining on wages is common;  
 2 = additional enterprise bargaining on wages occurs only in large firms;  
 1 = additional enterprise bargaining on wages is rare even in large firms;  
 0 = no additional enterprise-level bargaining on wages (or does not apply, if “level”=1).
- b. Canada, Estonia, Japan, Korea, Mexico, Poland and United States are not included because bargaining in those countries predominantly takes place at the local or company level over the entire period under consideration.

Source: Visser, J. (2015), ICTWSS Database, Version 5.0, Amsterdam Institute for Advanced Labour Studies AIAS.

The move towards decentralisation in many OECD countries is closely connected to the increased possibility of opening clauses – i.e. the ability to set aside the legal favourability principle which dictates that collective agreements can only deviate from the law (and that lower-level agreements can only deviate from higher-level agreements) in ways that are favourable for workers (Visser, 2013). In Portugal, collective agreements have been able to establish less favourable conditions than those prescribed by the law since the introduction of the Labour Code in 2003 (although, in 2009, the revised Labour Code then specified a number of areas that could not be object of less favourable dispositions in collective agreements), while firm-level agreements (in firms with 500 or more employees) have been able to deviate from higher-level agreements in a less favourable way since 2009. As discussed above, this possibility was extended to firms with 150 or more employees in 2012. In most other OECD countries where the predominant level of bargaining is at the sector/industry/national level, the widespread use of opening clauses in collective agreements only began at the beginning of this century (Visser, 2013) – although in a few countries, this is a far more recent phenomenon (e.g. Finland, Greece, Italy and Spain).

Opening clauses as discussed in the previous paragraph need to be distinguished from “inability-to-pay” (or “hardship”) clauses, which have also been on the rise across the OECD, and which allow temporary deviations from higher-level agreements for firms facing economic difficulties. As discussed above, Portugal introduced this possibility in 2014. Similarly, such clauses have been used by many other OECD countries during the recent crisis (e.g. Austria, Finland, Greece, Norway, Poland, Sweden, Slovenia and Spain). In a handful of countries, they were possible even before the crisis, though sometimes only informally (at least to start with). In Germany, for example, informal arrangements between works councils and employers which allowed deviations from collective agreements in order to save jobs started emerging in the 1990s, and were later institutionalised.

### *Extensions*

The extension of collective bargaining agreements is legally possible in around two thirds of OECD countries. The exceptions are: Canada,<sup>53</sup> Denmark, Greece (since 2011), Italy,<sup>54</sup> Mexico, New Zealand, Sweden, Turkey,<sup>55</sup> the United Kingdom and the United States. In the United Kingdom and New Zealand, extensions used to be possible, but were removed in the early 1980s and 1990s, respectively. While the advantages of extensions for non-unionised employees are obvious, employers may also have an interest in having collective agreements extended because it tends to remove competition on the basis of working conditions (including wages). In addition, extension practices may be particularly useful in countries where there are a large number of small firms (for whom the transaction costs of bargaining are too high) and may even act as an incentive for employers to join an employer organisation in order to get their voice heard.<sup>56</sup> However, as argued above, extensions may also have important negative consequences in terms of competitiveness and employment.

Amongst the countries where extensions are possible, important differences exist in terms of: i) how common such extensions are; ii) whether extensions apply to the whole (or only a part) of the agreements; and iii) what specific requirements need to be fulfilled for an extension to be granted. In some countries (including Portugal before the crisis), extensions are quasi-automatic and apply to virtually all agreements. These countries are: Austria, Belgium, Finland, France, Greece (before 2011), Slovenia and Spain. In other countries, there is a much more selective use of extensions. In Ireland, for example, extensions are only applied to wages and working conditions, and similar restrictions exist in Germany and in Norway also. Finally, in many countries specific requirements need to be met (often relating to the representativeness of the employers signatory to the agreement – i.e. the percentage of workers they represent) before an extension will be granted. Most commonly, the representativeness threshold is set at around 50%: e.g. Finland, Germany (until recently), Greece and Spain (for some procedures). In other countries, the thresholds can be lower (e.g. 30% in Switzerland in some sectors) or higher (60% in the Netherlands, or lower under certain conditions). Clearly, the right rule and threshold need to be adapted to the economic realities of each country.

The crisis brought about important changes to the practice of extensions in many countries, not just in Portugal. In some, extensions were temporarily suspended – sometimes deliberately (like in Greece), sometimes as a result of legal uncertainty (e.g. Ireland and the Slovak Republic). Estonia made a deliberate choice to drop automatic extensions, while the Czech Republic introduced the possibility of exemption for SME's and firms facing financial difficulties.

Interestingly, not all OECD countries decided to weaken the practice of extensions. In the Netherlands, for example, the government made it more difficult for firms to obtain an exemption from extensions, while in Germany the representativeness threshold for extensions to be granted was lowered. That being said, there are few countries where the number of extensions has increased over time – Germany, Norway and Switzerland being the only three exceptions (but these are countries where extensions were relatively rare or non-existent in the past – Eurofound, 2015). Overall, therefore, the practice of extending collective agreements has become less common during the crisis in OECD countries.

---

53. With the exception of Quebec.

54. In Italy, the courts tend to uphold minimum wage claims based on sectoral agreements for uncovered workers performing similar work, which serves as a functional equivalent to the practice of extension.

55. While there is an instrument for extension of collective agreements in Turkey, it is rarely used in practice (Uçkan, 2012).

56. On the other hand, extensions may reduce union membership as non-unionised workers are able to free-ride on the outcomes of bargaining rounds without having to pay a union membership fee (Blanchard, Jaumotte and Loungani, 2013).

Sometimes, this was as a result of temporary measures, but some countries have introduced permanent restrictions on the use of extensions. While there are obvious reasons for refraining from quasi-automatic extensions during times of crisis, it remains to be seen how the practice will evolve once countries return to higher rates of growth.

#### *Termination and continuation beyond expiry*

Until recently, collective agreements in a handful of countries (primarily in Southern Europe) would not expire unless they were replaced by new ones. The reasoning behind such rules is that they protect workers in cases where employers are unwilling to negotiate new terms. However, because they significantly strengthen the bargaining power of unions, such rules also make it much more difficult for employers who, during times of crisis, may need to negotiate less favourable terms in order to survive and/or avoid employment losses.

While Portugal already introduced the possibility of expiry of agreements without replacement in 2003<sup>57</sup> (and further reduced the length of time for which agreements with cessation clauses could remain valid during the recent reform period), Greece, Spain and Estonia only followed suit during the crisis. In Greece, the indefinite duration of collective agreements (*metenergeia*) was scrapped and replaced by a period of validity of between one to three years, while the after-effect period of agreements was reduced from six to three months. Upon expiry, all clauses of the agreement will cease to apply, except those on basic salary and allowances for maternity, children, education, and hazardous work. Similarly, the Spanish Government put an end to the practice of *ultra-actividad* in 2012, and the after-effect of collective agreements is now limited to one year. In the same year, Estonia removed the possibility of automatic continuation after expiry, and agreements can now only remain valid beyond expiry upon agreement between the signatory parties. Another practice which has emerged in some countries is to allow collective agreements to be terminated unilaterally by one of the signatory parties, like in Poland in 2002 (Eurofound, 2015; Visser, 2016). Overall, and despite the recent reforms, the legal requirements for the expiry of collective agreements remain more demanding and the minimum periods longer in Portugal than in other European countries (Naumann, 2014).

#### **Additional wage moderation was achieved by freezing the minimum wage and reducing overtime pay**

In a bid to restore competitiveness and save jobs, the government froze the minimum wage between 2011 and 2014, and cut the pay (and other compensation) for overtime work. In addition, attempts were made at cutting public sector wages, although the Constitutional Court blocked many of these cuts. These measures came on top of the reduction in collective agreements and extensions discussed above. As the next chapter will make clear, all these measures helped achieve some wage moderation during the crisis.

#### ***The minimum wage was frozen***

Traditionally updated in January of each year, the Portuguese minimum wage (*Retribuição Mínima Mensal Garantida*) was frozen at its January 2011 level of EUR 485 until October 2014, when it was increased to EUR 505. While the real minimum wage had been relatively stable prior to the crisis, it increased rapidly in the early stages of the recession (2008-2010). The freezing of the minimum wage in 2011 led to a slow erosion of its real value, but the 2014 increase brought the minimum wage back to a real level comparable to that observed at its peak in 2010 (Figure 18).

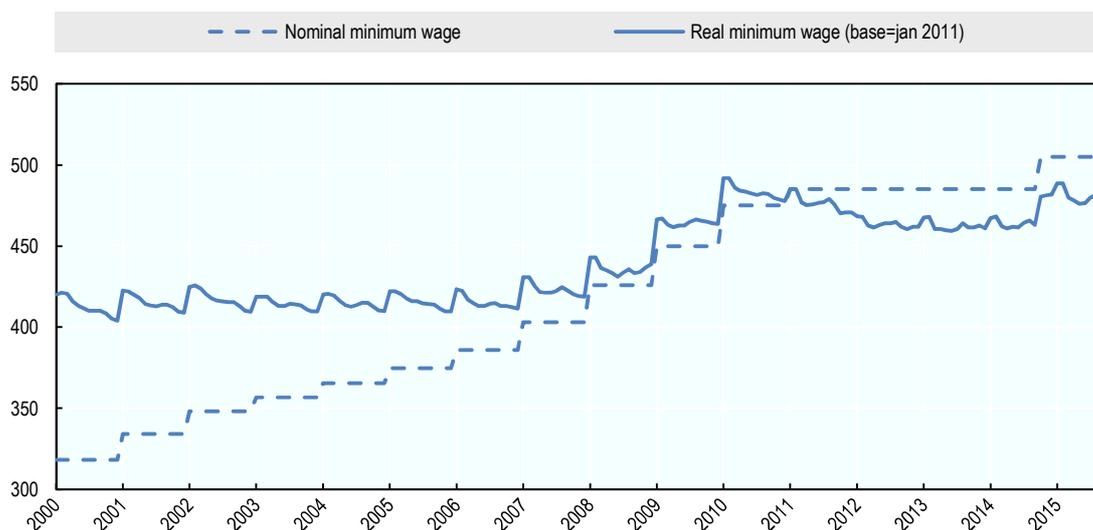

On average across the OECD, minimum wages rose as a proportion of median wages during the crisis – from 47.3% in 2007 to 50.2% in 2014. In Portugal, this increase was even greater (from 51.4% to 57.5%) and, in 2014, Portugal had the sixth highest minimum wage relative to median wages among all OECD

57. The 2006 revision of the Labour Code added an important rule which was that, if the signatories did not specify which conditions of the agreement was to transfer to the individual work contract upon expiry, then provisions related to pay, category and function would automatically be transferred (Naumann, 2014).

countries. Only Turkey, Chile, France, Slovenia and New Zealand had a higher minimum-to-median-wage ratio (Figure 19). While the cost to employers of the 2014 increase in the minimum wage was somewhat offset by a temporary<sup>58</sup> decrease of 0.75 percentage points in employer social security contributions on minimum-wage workers who were hired prior to June 2014, it is important to highlight that, in general, Portugal imposes relatively high employer social security contributions on minimum-wage workers compared to other countries in the OECD (OECD, 2015c). This will exacerbate the possible negative effect of a high minimum-to-median-wage ratio on employment.<sup>59</sup>

From the point of view of employees, however, Portugal imposes relatively low income taxes and social contributions, so that households pocket a large share of any increase in the minimum wage (much larger than in most other OECD countries; OECD, 2015c). At the same time, the freezing of the minimum wage has hurt workers and, in 2013, OECD analysis shows that minimum-wage workers needed to work a relatively high number of hours to be able to move above the relative poverty line: a lone parent with two children needed to work 50 hours per week at the minimum wage before earning 50% of median net household income, while one-earner couples with two children needed to work 62 hours to achieve the same (OECD, 2015c).

Figure 18. **Nominal and real levels of the Portuguese minimum wage, January 2000 to September 2015**

Note: Real minimum wage obtained using the monthly Consumer Price Index; base= January 2010.

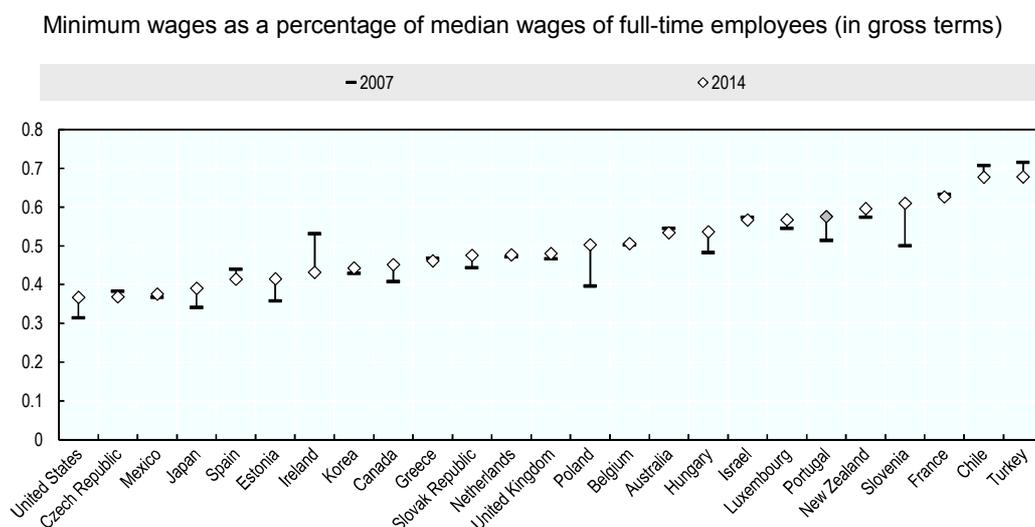

Source: OECD Minimum Wage Database and OECD Economic Outlook Database.

In conclusion: while recent increases in the minimum wage are to be welcomed from a worker perspective, they should raise some concern for employers, particularly because employer taxes and social security contributions on minimum-wage workers are relatively high in Portugal.

58. This measure was set to expire in January 2016.

59. Two studies have shown that minimum wages have (small) negative effects on employment in Portugal (Centeno, Duarte and Novo, 2011; Carneiro et al., 2011). These findings are consistent with the wider, international evidence which has shown that moderate increases in a moderate minimum wage are unlikely to have significant negative employment effects – although more vulnerable groups might be slightly more adversely affected (OECD, 2015c).

Figure 19. Minimum wage levels pre- and post-crisis, 2007-2014

Note: Countries are ranked in ascending order of the MW/Median ratio in 2013. 2009 instead of 2007 data for Mexico. 2013 instead of 2014 data for Japan and Korea.

### *Compensation for overtime work was reduced*

Most countries across the OECD regulate standard workweek hours and have laws in place that dictate additional compensation for overtime work. The primary motivation for such legislation is to protect workers' safety and well-being. In addition, some analysts believe that restrictions on overtime work could promote employment: by reducing the number of hours worked by each individual worker, regulations on overtime force employers to hire new workers instead. However, the evidence does not support this claim. If anything, it has been found that greater restrictions on overtime work (including higher overtime premia) raise labour costs and result in a reduction in overall employment (Oaxaca, 2014).<sup>60</sup> While seemingly counterintuitive, there are various reasons why reductions in the number of overtime hours will not create additional employment. One of these is that overtime tends to be carried out primarily by skilled workers, and such work cannot easily be done by unskilled workers. Another reason is that restricting overtime work induces workers affected by such measures to look for second jobs, which creates additional competition for existing jobs. Finally, if jobs consist of a given package of compensation and working conditions, then reductions in overtime pay could simply be compensated for by increases in other types of pay (base wages or other pay) (Trejo, 1991).

In a bid to reduce wage costs, Portugal cut compensation for overtime work by half and revoked the right to paid compensatory time off. In addition, the government suspended until the end of 2014 all clauses regarding overtime pay and compensatory time off contained in collective agreements and employment contracts. Finally, by promoting the use of working time accounts (see next section), employers were offered a cheaper alternative to using overtime work.

60. Similarly, experiments with work-sharing in a number of European countries during the 1980s and 1990s – based on the belief that reducing the average number of hours worked by each employee would result in the creation of new jobs – have not resulted in any employment effects. If anything, the employment effects of such schemes have been negative (Kramarz et al., 2008; Andrews et al., 2015).

Cuts to overtime pay were controversial, especially since they resulted in reductions in earnings for some workers highly dependent on overtime hours. Távora and González (2015) show how some employers kept paying overtime at the pre-reform rates, in return for other concessions from workers. Indeed, new evidence produced by the OECD suggests that there may have been some compensation for cuts in overtime pay through greater increases in base wages and/or in hours worked (see Box 11). At the same time, there is little evidence that the reduction in overtime pay may have reduced employment growth. If anything, there might have been more employment growth in firms that increased their use of overtime.<sup>61</sup> This is because, as argued in Box 11, the main driver of overtime use (and employment growth) is firm performance, and not the rate at which overtime is paid. In a way this is not surprising given that overtime pay actually represents a very small portion of firms' overall wage bill (see Box 14 in Chapter 2).

#### Box 11. Overtime pay rates, overtime use, and employment growth following the reform of overtime

This box uses data from the *Quadros de Pessoal* to analyse the effects of the change to overtime compensation on overtime pay rates, the use of overtime, employment growth, hours worked, and other wages. All results are for the private (non-agricultural) sector.

##### Hourly overtime compensation fell

The reforms of overtime compensation had a significant impact on hourly overtime pay rates in Portugal which, between 2011 and 2012, fell by 16.7% (13.4%) among workers working (firms using) overtime. While 79.4% (74.4%) of employees (firms) who worked (used) overtime in both 2011 and 2012, saw a reduction in their hourly overtime compensation, only 13.7% (21.8%) experienced an increase. The decision to reduce overtime pay rates appears to have been influenced by firm performance: among firms that did not reduce overtime pay rates, turnover increased by 5.6% on average (compared to just 2.3% among firms that reduced overtime pay rates).

##### The use of overtime decreased as well

Despite the strong reductions in hourly overtime compensation, the use of overtime did not increase. Before the reform, 7.6% (3.6%) of employees (firms) worked (used) overtime, while after the reform the incidence of overtime was 6.3% (3.4%) among employees (firms). Similarly, the average monthly number of overtime hours per employee was 1.20 prior to the reform, and 1.07 after.

The reduction in the use of overtime is not surprising, given that the reform was introduced at the trough of the recession, when demand was low and employers were shedding workers rather than needing more of their time. In addition, the reform coincided with the introduction of the individual working time accounts, which may have reduced the use of classic overtime work. While some firms did increase their use of overtime, this was generally because they were performing well: 41.5% of firms that increased their use of overtime experienced an increase in turnover, compared to 28.3% of firms reducing their use of overtime. It is also not the case that firms that started using more overtime were more likely to cut overtime pay rates: regardless of whether they increased or reduced overtime use, 75% of firms on average lowered the hourly overtime rate.

##### There is no indication that the reform harmed employment growth

A key concern is that, by reducing the cost of overtime, the reform may have hampered the creation of new jobs. This might be particularly true in a recovery, when demand is picking up but firms are still uncertain about future growth and prefer to use existing employees more, rather than risking to take on new ones. That being said, if the overtime wage rate is reduced and firms do not increase hours worked in response, then the savings obtained might be reinvested by firms into hiring new employees – and so the employment effect of the cut in overtime compensation could in fact be positive.

The data do not indicate that there was any substantial substitution of overtime use for employment growth. In fact, firms that both cut their overtime pay rate and increased the use of overtime also had larger employment growth than average (6.1% versus 0.2%). Just as with the use of overtime, the primary determinant of employment growth is firm performance: employment grew 10.5% in firms where turnover increased, while it fell by 4.3% in the other firms.

61. Martins (2016a) also finds that firms that cut overtime premiums experienced greater increases in employment.

**Box 11. Overtime pay rates, overtime use, and employment growth following the reform of overtime (cont.)**

**Cuts in overtime pay rates were compensated for by increases in hours worked and/or other wages**

Another interesting (and related) question is whether any reductions in hourly overtime pay were compensated for by increases either in other types of pay, or in the number of hours worked. Indeed, the reform was controversial as it reduced the incomes of certain employees who heavily relied on overtime work, and there is anecdotal evidence that some firms compensated the reduction in overtime pay for those workers by increasing their base wage. The Portuguese *Quadros de Pessoal* data show that the hourly wages (excluding overtime) grew slightly more for employees who experienced a drop in their overtime wage rate (0.48% versus 0.36%). Similarly, the probability of an increase in total hours worked (including overtime) was significantly greater for employees who had their overtime pay rate cut (41.8% compared to 11.6% on average). These figures indicate that the impact of the reduction in the overtime pay rate on total pay was mitigated through increases in both other wages and hours worked.

The above results (i.e. that the reduction in overtime pay rates was not associated with an obvious increase in the use of overtime or decrease in employment growth – and that there was some compensation for the losses in overtime pay by increases in other wages and hours worked) are not entirely surprising, given that total overtime pay only represents a very small fraction of firms' average wage bill per employee (see Box 14 in Chapter 2 for further detail).

***Public sector wages were cut***

In addition to freezing the minimum wage, the government cut the wages of civil servants earning more than EUR 1 500 in 2011 (by 3.5% to 10%). It also attempted to further cut public sector wages by: i) suspending the 13<sup>th</sup> and 14<sup>th</sup> monthly salary payments for those workers earning EUR 1 100 or more per month; ii) suspending the equivalent of one of those payments for workers with monthly salaries between EUR 600 and EUR 1 100. However, Portugal's Constitutional Court ruled that these cuts were unconstitutional and that the payment of bonuses should be resumed in 2013. These cuts were nevertheless implemented in 2012. In addition, in 2013, the government increased the working hours of public sector workers from 35 to 40 hours per week, without any increase in pay.

The government reintroduced similar public sector wage cuts, albeit more significant and also for civil servants earning below EUR 1 500 per month, as part of its 2014 Budget Law. Once more, these cuts were ruled unconstitutional (in May 2014) and were only implemented in the first five months of 2014. Other provisions contained in the 2014 Budget Law with an impact on public sector wages (such as overtime pay reductions and uncompensated longer work weeks) were not challenged. Given that the ruling of the Constitutional Court had severe implications for public finances, the government launched a new austerity package in 2014, which again cut public sector wages over the period 2014-2018 at rates comparable to those applied in 2011. These measures were immediately brought before the Constitutional Court (August 2014), which ruled that the cuts for 2014 and 2015 were constitutional, but that it was not acceptable to implement wage cuts for a more extended period than the one fixed for the implementation of the Memorandum of Understanding on Specific Economic Policy Conditionality, which lasted until May 2015.<sup>62</sup>

62. The XXI Constitutional Government reversed previous cuts in public sector wages by the end of 2016, and returned from the 40-hour week introduced in 2013 to the old 35-hour week in July 2016.

### ***Working time has become more flexible to contain employment fluctuations over the cycle***

Adjustments in labour input in response to adverse conditions can happen either along the extensive margin (i.e. reducing the number of people in work) or along the intensive margin (i.e. reducing the hours of people in work). Avoiding unnecessary redundancies is obviously preferable from the employees' point of view, but also for employers because it allows them to hold on to employees (and firm-specific human capital) and avoid costly hiring and firing procedures. From society's perspective, it mitigates the costs of higher unemployment, including expenditure on unemployment benefits.

In contrast to some other OECD countries, the adjustment in labour input to the crisis in Portugal occurred primarily through job destruction. There are many factors which determine the choice of adjustment mechanism (hours versus jobs), but making sure that employers have the flexibility to adjust working time is one of them. In particular, there is evidence that short-time work compensation schemes helped preserve jobs in a number of OECD countries during the crisis (OECD, 2010b). In addition, working time accounts played an important role in countries such as Germany.

Such schemes existed in Portugal prior to the crisis, but the evidence suggests that they were used very little. To encourage employers to use such measures in the future, Portugal reduced the procedural requirements and time needed to implement short-time work compensation schemes (*redução temporária do período normal de trabalho ou suspensão do contrato de trabalho*), and also introduced additional safeguards to reduce the deadweight loss incurred by them. In addition, individual working time accounts (*banco de horas*) were introduced alongside the collective working time accounts already in place, and it was made easier to extend the latter to workers not covered by collective agreements.<sup>63</sup>

While there appears to have been a slight uptake of short-time work and working time accounts following the reforms, this probably came too late to make a significant difference to job destruction during the recent recession. In addition, and despite the reform, the take-up of flexible working time arrangements may remain low in Portugal as long as there is a high share of temporary employment, which makes it easy for firms to adjust labour inputs along the employment margin.

### ***In Portugal, the adjustment in labour input to the crisis occurred primarily through job destruction***

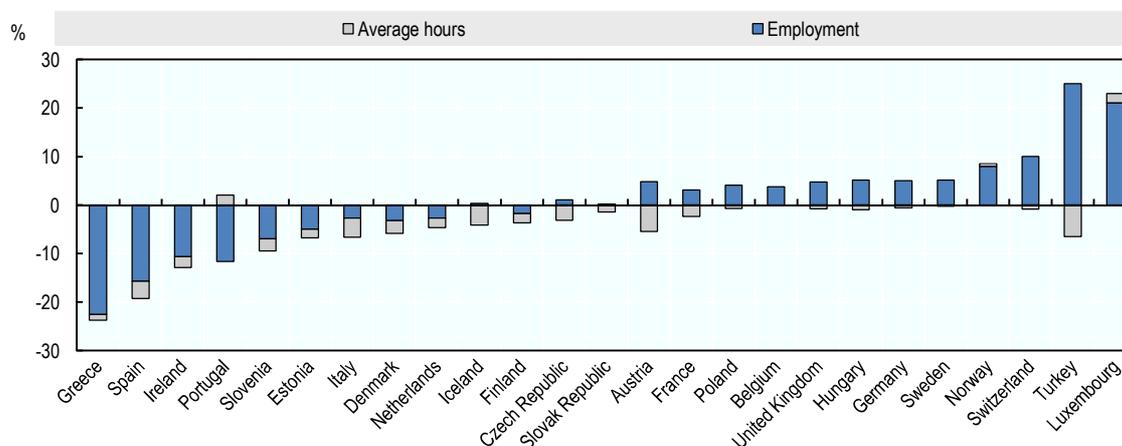

A decomposition of the reduction in total hours worked during the crisis shows that, in Portugal, this fall can be attributed entirely to employment losses,<sup>64</sup> while in other countries a reduction in average hours worked played a more important role (Figure 20). OECD (2010b) showed that, in some countries, the decline in employment during the crisis was small compared to what would have been expected given the size of the decline in output, and that this was due in large part to reductions in average hours worked.

63. The XXI Constitutional Government has announced plans to abolish the possibility of individual working time accounts established upon agreement between the employer and employee. Instead, there would be a return to the pre-reform situation where such working time accounts could be established only by collective agreement (Government of Portugal, 2015).

64. One of the contributing factors to these employment losses is the fact that a very large share of Portugal's businesses is made up of micro/small enterprises, with low survival rates during times of crisis. Indeed, Carneiro, Portugal and Varejão (2014) show that the closing of existing firms contributed significantly to overall employment losses.

Figure 20. Decomposition of the change in total hours worked, 2007-2014

Change in total hours worked that can be attributed to changes in employment and average hours worked, respectively

Note: Countries are ranked in ascending order of the percentage change in total hours worked. Covers all ages 15+. Because of a methodological change in the Portuguese Labour Force Survey, data prior to 2011 are not fully comparable with the more recent data. The new methodology results in higher levels of unemployment and inactivity compared to the methodology used prior to 2011. For detailed information, see Statistics Portugal (2011).

Source: Eurostat.

### ***In some countries, short-time work compensation and working time accounts played an important role in preserving jobs during the crisis***

There are many factors that determine the extent to which labour input adjustments are made along the intensive margin (hours worked) as opposed to the extensive margin (employment) – including differences in the nature of the shock and the structure of the economy. However, making sure that employers have the flexibility to adjust working time in response to changing demand conditions is one of those reasons.

For example, there is evidence that short-time work compensation played an important role in preserving jobs during the crisis in a number of OECD countries, including in Germany, Japan, Belgium and Finland (OECD, 2010b). Convincing employees to reduce working time during a crisis may be difficult for employers since it implies a significant loss in earnings. If, however, the government compensates some of that loss and ensures that employees still earn more than they would receive in unemployment benefits, they might be more easily persuaded. While such publicly sponsored schemes to support temporary reductions in working time or lay-offs were possible in Portugal even prior to the crisis (*redução temporária do período normal de trabalho ou suspensão do contrato de trabalho*), they appear to have been rarely used (MTSS 2006). In comparison, countries which experienced a fall in GDP in 2009 similar to that of Portugal (e.g. Austria, the Netherlands, Switzerland and the United States) had much greater incidence of short-time workers in the labour force (see Figure 21).

Similarly, there is evidence that working time accounts (or banks) have helped preserve jobs during the crisis in countries like Germany (Zapf and Brehmer, 2010). These schemes allow employers to increase hours worked (within certain limits) when demand is high, and then to run down the accumulated time when demand is low. Again, while such flexibility has been available to employers in Portugal since 2009, it has been used relatively little in practice (Monteiro Fernandes, 2012).

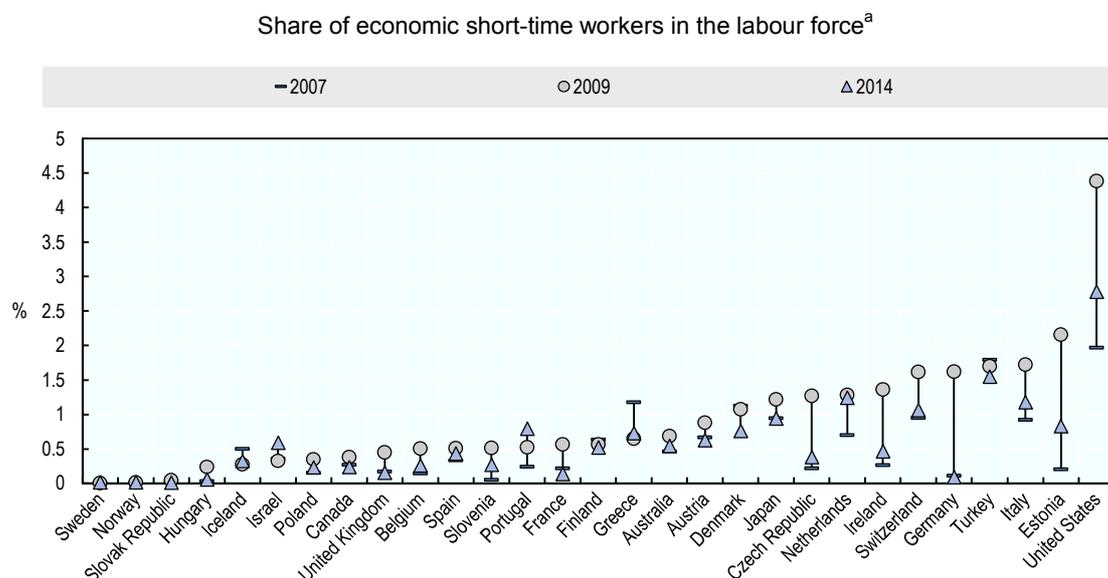

### *Portugal introduced a number of reforms to facilitate the use of flexible working time arrangements*

Towards the middle of 2012, Portugal introduced a number of changes that would make it easier for employers to use short-time work compensation as well as working time accounts. The procedural requirements and time needed to implement short-time work arrangements were reduced. In particular, the notice period employers need to respect to inform workers of the measure to be applied was shortened (with a possibility to implement immediately if the works council agrees), and the workers' representative body can no longer oppose an extension of the short-time working arrangement as long as the employer follows the necessary communication procedures.

A second reform involved the introduction of individual working time accounts alongside the collective working time accounts already in place, and it was made easier to extend the latter to workers not covered by collective agreements. Under the previous rules, working time accounts had to be regulated by collective agreement. As pointed out by Távora and González (2015), the new rules therefore decentralised decisions around internal flexibility to the firm.

Figure 21 suggests that the share of economic short-time workers in Portugal has increased over time. Interestingly, Portugal is one of the only countries where the use of short-time work has risen between 2009 and 2014, which could reflect the fact that such measures are now easier to implement. In most other countries, the peak was reached in 2009, and there was a substantial reduction in the use of short-time work by 2014. While international comparative data is not available, Table 4 shows that the number of workers covered (firms using) working time accounts in Portugal was 2.5 (1.3) times higher in 2014 than it was in 2010. That being said, the proportion using working time accounts remains relatively low (2% of workers and less than 1% of firms). In addition, because these reforms came so late in the crisis, it is highly unlikely that they will have had a significant impact on stemming job losses. As Chapter 2 will show, Portugal started emerging from the crisis in early 2013.

**Portugal also improved the design of short-time work compensation schemes to reduce their deadweight loss**

While the majority of OECD countries operated a short-time work compensation scheme during the crisis, OECD (2010b) showed that there are important differences in the design of such schemes across countries which may affect their relative success at stemming job losses. In particular, such design features can influence: i) the amount of deadweight loss such schemes incur (i.e. the subsidisation of jobs which would have been kept even in the absence of the subsidy) as well as ii) their displacement effects (i.e. the preservation of jobs that are not viable without the subsidy, even after business conditions improve). Among the main characteristics of short-time work schemes OECD (2010b) distinguishes:

- *Work-sharing requirements* which specify how working time reductions are to be distributed across the workforce of participating firms, including by setting a minimum number or share of employees who must participate, or limits on the minimum or maximum hours reductions.
- *Eligibility requirements* which set conditions that employers or employees must meet in order to participate in the programme (e.g. minimum reduction in production and/or sales; or an explicit agreement between the social partners).
- *Conditionality requirements* which set behavioural requirements for employers and employees participating in short-time work schemes (e.g. prohibitions of dismissals during or, in some cases, for a short period after participation in short-time work schemes; the development of recovery plans).
- The *generosity* of a short-time work programme which determines the cost of participation for both firms and employees, as well as the maximum duration for which income support is available.

As part of the reform of short-time work compensation, Portugal attempted to reduce the deadweight losses of such schemes by: imposing a 30% contribution of the employer to the financial compensation paid to the worker; providing financial incentives to encourage workers to take up training while not working; and banning firing in the period immediately after the end of the scheme. While these requirements and the generosity of short-time work schemes can be tightened so as to reduce deadweight losses and displacement effects, it is important to bear in mind that there is also an important trade-off in terms of the uptake of such schemes: the higher the administrative burden placed on firms, the higher the probability that the latter will be deterred from participating in them.

***Short-time work compensation also has its limitations***

While short-time work compensation schemes can help avoid unnecessary job losses during a crisis, there are also some risks attached to their use. For instance, they tend to benefit permanent employees primarily, and may therefore exacerbate the labour market divide between permanent employees and those on temporary and part-time contracts.<sup>65</sup> In addition, and particularly where they are overly generous, such schemes may result in the preservation of inefficient job matches and prevent the reallocation of labour to more productive uses. This may also hinder hiring during the recovery and, for this reason, the OECD has previously suggested that the use of short-time work schemes be discouraged as the economy enters into recovery (OECD, 2010b). These limitations highlight the fact that short-time work compensation should be seen as just one of many ways of reducing working hours during periods of slack. Other methods include working time accounts, reductions in overtime, as well as reductions in working time on the initiative of employers. Under certain circumstances, such alternative schemes may even achieve a more tailored and efficient outcome than a government-led scheme (Cahuc, 2014).

Finally, it is not clear that, even after the reforms, employers in Portugal will make much use of reductions in working time to respond to changing market conditions. In fact, one possible reason for the low take-up of such measures in some countries (e.g. France) is that they have a high share of temporary employees, which makes it easier to make adjustments by shedding labour (Gonthier, 2012). As long as the Portuguese labour market remains highly segmented, labour input adjustments may therefore continue to be made primarily by reducing temporary employment.

---

65. Such an argument would apply equally to the use of working time accounts.

**CHAPTER 2****RECENT LABOUR MARKET DEVELOPMENTS AND OUTSTANDING CHALLENGES  
IN PORTUGAL**

The Portuguese labour market reforms were a move in the right direction. Since economic growth turned positive again in early 2013, Portugal has experienced significant improvements in both employment and unemployment rates – greater, in fact, than what one would have expected given the pace of the recovery. However, despite the progress made, many challenges remain. Unemployment remains high (particularly among youth) and this situation has fuelled an increase in both poverty and long-term unemployment (although there are signs of improvement in the latter). The labour market remains highly segmented and, in the context of very low inflation, the presence of downward nominal wage rigidity is likely to remain a barrier to the competitiveness of the Portuguese economy – unless productivity growth is strengthened.

The statistical data for Israel are supplied by and under the responsibility of the relevant Israeli authorities. The use of such data by the OECD is without prejudice to the status of the Golan Heights, East Jerusalem and Israeli settlements in the West Bank under the terms of international law.

The labour market reforms that Portugal implemented over the period 2011-2015 were described one by one in the previous chapter. While the possible impact of each of these measures was also discussed, this was always done in isolation, assuming a *ceteris paribus* (“all other things held constant”) view of the world. Yet the sheer number of reforms that were undertaken over this period makes it clear that such analysis will only be partial. Indeed, there will be important complementarities between the measures implemented, as well as effects which cancel each other out. There is a need, therefore, to look at the overall evolution of the Portuguese labour market over the reform period.

One should be careful, however, in ascribing general trends in labour market outcomes (whether good or bad) to the reforms that were undertaken. Indeed, establishing any form of causality between the reforms and changes in labour market indicators is complicated by the following facts:

1. The reforms were implemented over a relatively long period of time, which makes it impossible to identify a clear “before” and “after” for the purpose of evaluation.
2. Not much time has elapsed since the labour market reforms, yet some of the measures will take time to produce their full effect and so it may be too soon to evaluate them.<sup>66</sup>
3. Important reforms have been implemented in areas other than employment, which may also have an effect on the labour market.
4. The reforms coincided with a second dip in GDP growth and a gradual recovery. Disentangling the effects of the reforms from those of the economic cycle is notoriously difficult.

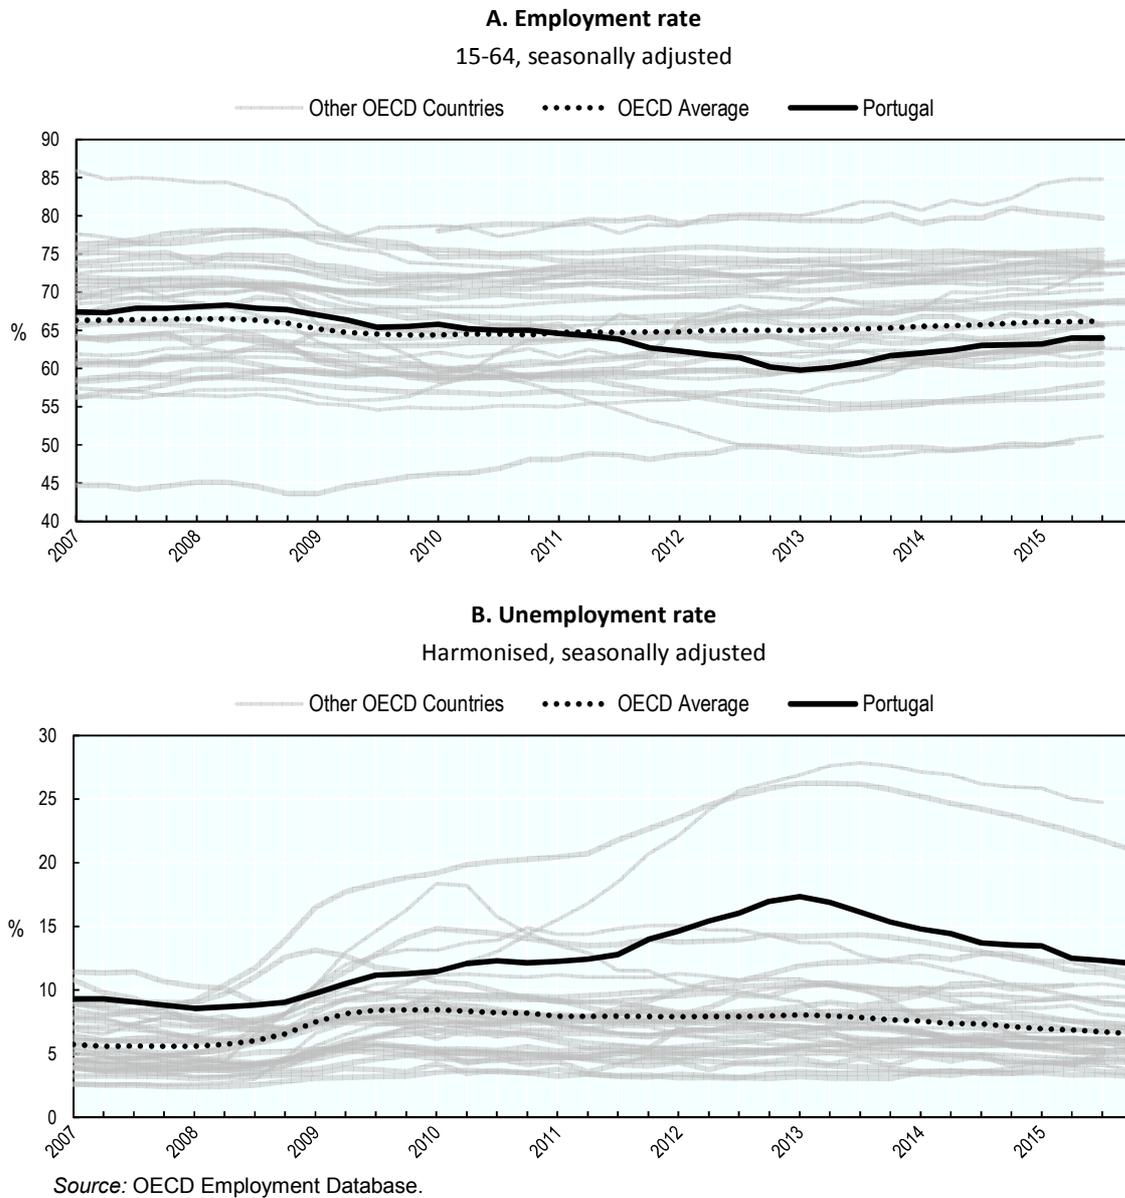

Given these difficulties, the purpose of this chapter is: i) to stand back and provide a descriptive overview of the evolution of some key indicators for the Portuguese labour market over the past few years; and ii) to identify the key challenges that lie ahead.

### **Portugal is moving out of recession and there have been significant improvements in the employment and unemployment rates**

After a prolonged period of negative growth, Portugal is starting to emerge from the crisis. Since the beginning of 2013, there have been significant improvements in both the employment and unemployment rates. The Portuguese employment rate, higher than the OECD average prior to the crisis, fell below the OECD average in 2011, where it remained mid-2015 (Figure 22). It reached its trough at the beginning of 2013 (59.8%), but has seen a significant improvement since. Between the first quarter of 2013 and the final quarter of 2015, the Portuguese employment rate rose by 4.5 percentage points – the third highest rate of increase after Hungary and Iceland, and considerably higher than the 1.6 percentage point rise observed across the OECD on average. The unemployment rate in Portugal saw a very sharp increase during the crisis: from 8.6% at the beginning of 2008 to a peak of 17.3% at the beginning of 2013 (Figure 22), when it was second only to the unemployment rates observed in Spain and Greece. Like the employment rate, however, the Portuguese unemployment rate has seen significant improvements between the first quarter of 2013 and the final quarter of 2015: a fall of 5 percentage points (compared to 1.5 percentage points across the OECD on average). Importantly, the decline in unemployment observed in Portugal is much sharper than what one would have expected given GDP growth and the relationship between GDP growth and unemployment observed in the past (see Box 12). While this should not be interpreted as causal evidence that the reforms are having a positive impact on the labour market, these findings are at least consistent with the impact that would be expected from the reforms.

66. One of the reasons why the measures will take time to produce their full effect is that the impact of some of the reforms, particularly those of employment protection legislation, will depend on the interpretation of these laws by the courts and, therefore, the build-up of case law which will influence individuals’ future behaviour.

Figure 22. Employment and unemployment rates, Q1 2007-Q4 2015

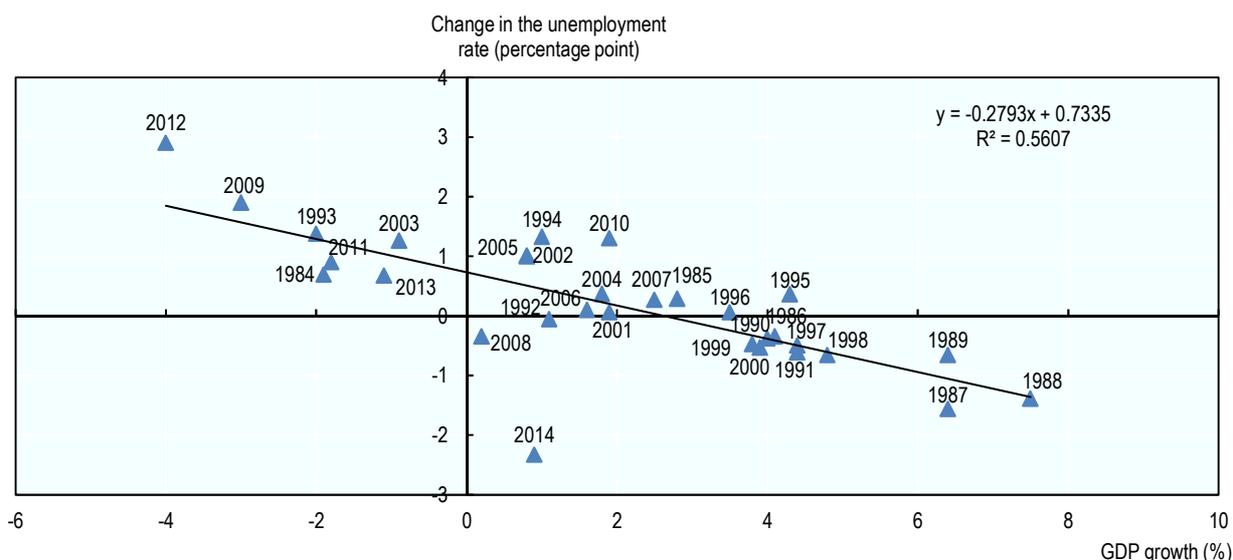

### Box 12. Portugal's strong recovery: How unemployment is falling more sharply than predicted

A well-known stylised fact in economics is the robust relationship between short-term GDP growth and changes in the unemployment rate. This relationship is known as Okun's law, referring to the finding of Okun (1962) that in the United States a 1% increase in real GNP was associated with a 0.3 percentage point drop in the unemployment rate. The existence of a negative relationship has been found for different time periods and countries, although there is substantial variation in the magnitude of the correlation coefficient (Ball, Leigh and Loungani, 2011; Cazes, Verick and Al Hussami, 2013).

Figure A plots this correlation for Portugal for the period 1984-2014 and clearly shows a negative relationship between output and unemployment growth: a 1% increase in real GDP is associated with a 0.28 percentage point drop in the unemployment rate. However, whereas the majority of the observations are very close to the fitted linear regression line, the observation for 2014 is a clear outlier, combining very modest GDP growth (0.9%) with a sharp drop in the unemployment rate (-2.3 percentage points). It seems, therefore, that a departure from the previously observed relationship between output and unemployment growth can be observed during the present recovery, starting in 2013. Indeed, dropping 2013 and 2014 from the sample increases the correlation coefficient (to -0.3) and improves the fit of the regression line (to an  $R^2$  of 0.76).

Figure A. Okun's Law in Portugal, 1984-2014

Relationship between growth in GDP and changes in the unemployment rate

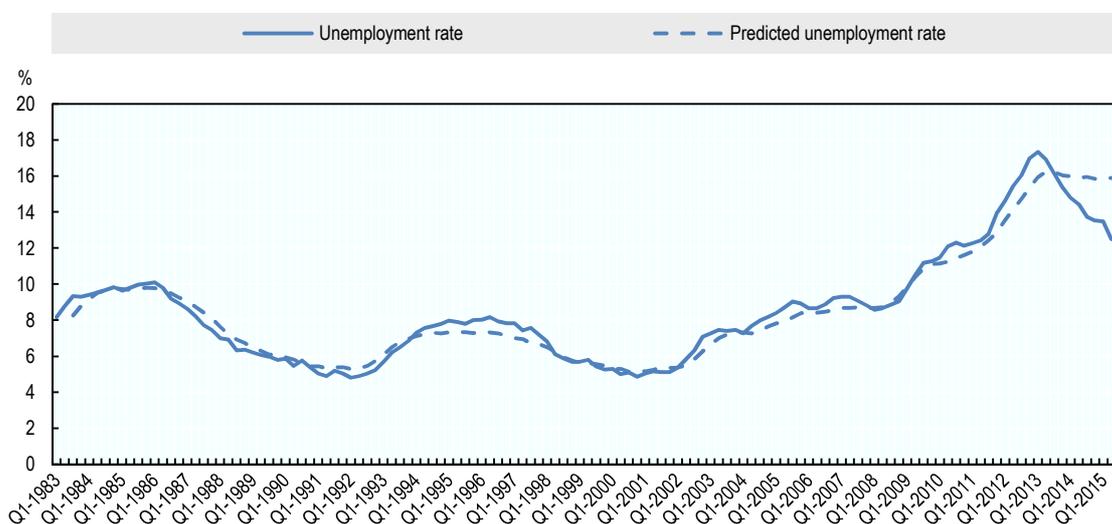

Source: OECD Quarterly National Accounts Database, OECD Short-Term Labour Market Statistics Database.

The departure from the previously observed relationship between output and unemployment growth can be seen even more clearly in Figure B, which compares the actual unemployment rate to the predicted unemployment rate based on the observed relationship between GDP and unemployment rate growth over the period Q1 1984 to Q3 2011 (i.e. prior to the labour market reforms). Whereas the evolution of the predicted unemployment rate follows the trend of the actual unemployment rate closely in most years, including during the most recent recession, there is a big gap between the predicted and actual rates from the second half of 2013 onwards. While according to the predictions, the return to modest growth should have resulted in a levelling off of the unemployment rate, in reality there has been a sharp drop. It would appear, therefore, that the Portuguese labour market has been recovering much faster from the recession than one would have predicted based on pre-reform data, and these findings are in line with those of the European Commission (2015). However, one should also bear in mind that, over the same period, there was a large increase in emigration as well as in the number of unemployed participating in active labour market programmes. Both these factors may have contributed to the pattern observed above.

## Box 12. Portugal's strong recovery: How unemployment is falling more sharply than predicted (cont.)

Figure B. Predicted and actual changes in the unemployment rate, Q1 1983 to Q3 2015

Note: The predicted unemployment rate is estimated by regressing quarterly changes in the unemployment rate on the quarterly GDP growth rate for the period Q1 1984 to Q3 2011, including two lags each for GDP growth and the change in the unemployment rate. The predicted unemployment rate is constructed by adding the predicted change in the unemployment rate to the actual unemployment rate observed in Q1 2001.

Source: OECD analysis based on the OECD Quarterly National Accounts Database and the OECD Short-Term Labour Market Statistics Database.

While not proving that the reforms have had the intended effects, these findings are at least consistent with what one would expect. As argued in Chapter 1, the changes to severance pay rules will only slowly change firing behaviour, since accumulated rights were largely preserved. This may be why unemployment did not rise more than expected when GDP was falling, even after the reforms had been implemented. However, the changes to EPL should imply immediate effects on hiring when growth picks up since new hires start accumulating severance pay under the new rules, which significantly reduced the cost of hiring. Indeed, a preliminary OECD assessment of the severance pay reforms in Portugal suggests that they may have had a relatively large effect on hiring.

Al Hussami (2013), "Why did unemployment respond so differently to the global financial crisis across countries? Insights from Okun's Law", *IZA Journal of Labor Policy*, Vol. 2/10; Okun, A.M. (1962), "Potential GNP: Its measurement and significance", *American Statistical Association, Proceedings of the Business and Economics Section*, pp. 98-104.

### A key challenge consists in reducing high rates of youth unemployment

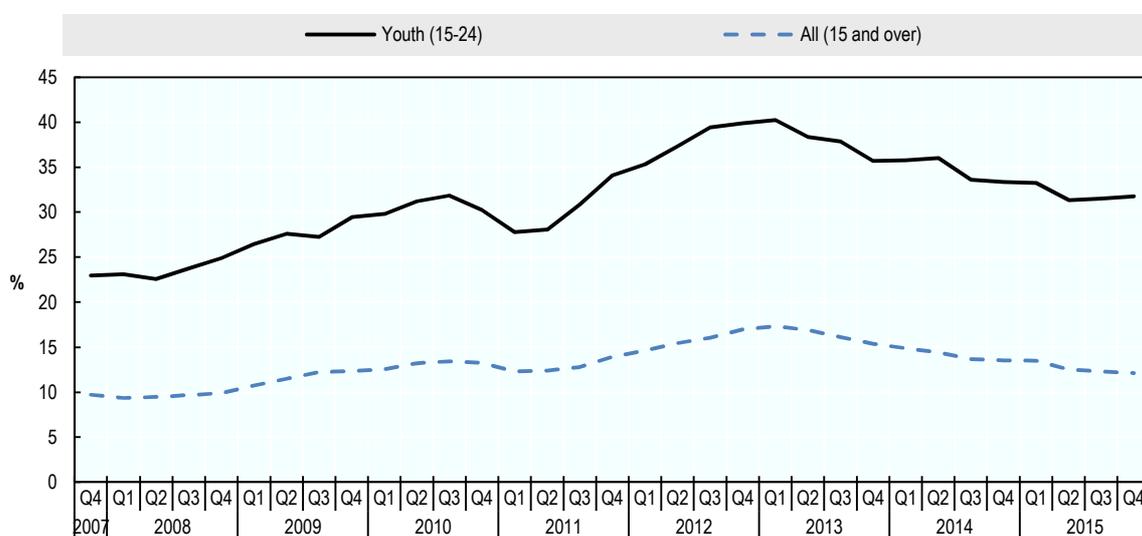

Despite recent improvements, the unemployment rate in Portugal remains high – and certain population groups are more affected than others. A particularly pressing concern going forward is the unemployment rate amongst youth. Young people in Portugal were disproportionately affected by the crisis and, at its peak, youth unemployment stood at 42.5% – 2.3 times the overall unemployment rate (Figure 23). While youth unemployment has also been falling since the beginning of 2013 it remains nearly twice as high as before the crisis. In the third quarter of 2015, Portugal had the 4<sup>th</sup> highest youth unemployment rate in the OECD, after Spain, Greece and Italy.

The disproportionate increase in youth unemployment during the recession also occurred in some other OECD countries, particularly those where (like in Portugal) there is a large gap in employment

protection legislation between temporary and permanent contracts. In those countries, youth are often hired on temporary contracts, with little hope of moving to a permanent position. When a recession hits, it is workers on temporary contracts (and therefore youth) who are most likely to lose their job (Casado, Fernandez and Jimeno, 2015). Further reforms of EPL to reduce labour market duality should therefore be seen as a key ingredient for improving the labour market outcomes of youth in Portugal.

Of course, EPL is not the only front on which youth unemployment should be addressed. Investing in skills, providing adequate income support to the unemployed, putting in place cost-effective active labour market measures, and tackling demand-side barriers are equally important (OECD, 2013a). It is also essential to intervene early to prevent youth at the margins of the labour market from falling into inactivity – after which it becomes much harder to reintegrate them into the labour market. At the European level, there has been a push for member states to adopt a “Youth Guarantee” – a new approach to tackling youth unemployment and inactivity which ensures that all young people under 25 get a good quality, concrete offer (either a job, apprenticeship, traineeship or continued education) within four months of leaving education or becoming unemployed. At the end of 2013, Portugal also adopted a Youth Guarantee, building on the earlier *Impulso Jovem* – a strategic plan to tackle youth unemployment launched in June 2012 and built on four pillars: internships (*Estágios Emprego*), hiring incentives (*Apoios à Contratação*), vocational training (*Formação Profissional*) and entrepreneurship support (*Empreendedorismo*). A more detailed description of these measures is given in Annex A. Going forward, the Portuguese Government should make sure that the Youth Guarantee programme in Portugal is adequately resourced, offers quality and sustainable solutions, and targets the hardest-to-reach (and not just the job-ready). A key challenge here will be to reach out to those youth who are not registered with the Public Employment Service.

Figure 23. Youth unemployment rate, Q4 2007-Q4 2015

Source: OECD Employment Database.

### The incidence of long-term unemployment remains high and continues to rise

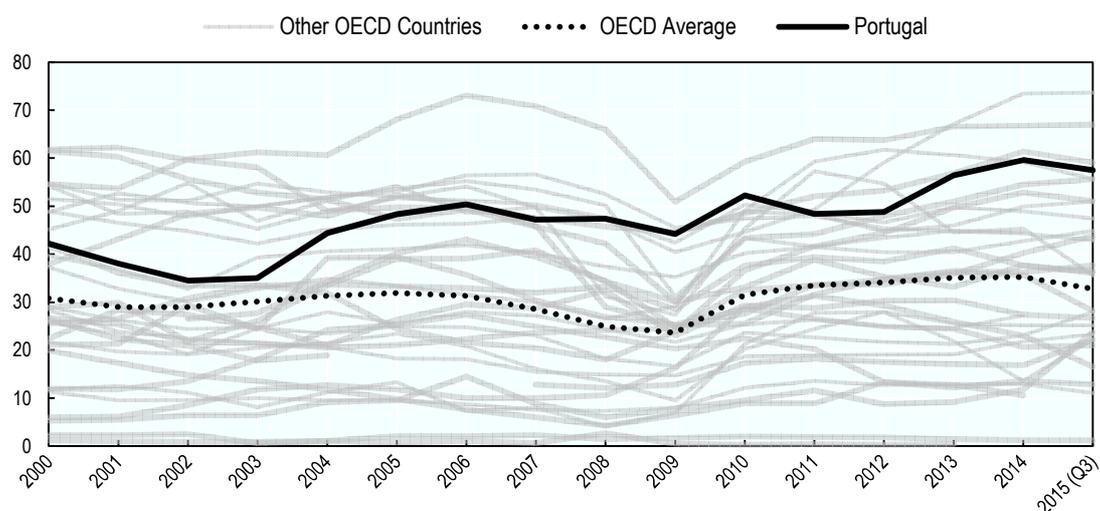

Another challenge the Portuguese labour market faced even prior to the crisis was the high incidence of long-term unemployment, and the reforms of unemployment benefits and activation policy discussed in the previous chapter sought to address this. Some evidence was presented that the strengthening of activation measures has had a positive impact on the monthly reemployment probabilities of the unemployed (Martins and Pessoa e Costa, 2014) – however the reductions in maximum benefit duration

will take time to make their impact felt, as they will only apply from the second unemployment spell after the reform onwards. In addition, the initial evidence suggests that the reductions in benefit levels have not (yet) had an impact on the transition from unemployment to employment.

Moreover, economic conditions remain difficult in Portugal and, while the unemployment rate has fallen in recent years, long-term unemployment remains high and has only been declining slowly since the start of 2015 (Figure 24). In the third quarter of 2015, 57.5% of the unemployed had been out of a job for a year or more, compared to 47% in the third quarter of 2007. Part of the rise in long-term unemployment will reflect a composition effect, as those who have been unemployed least long are most likely to be exiting unemployment as the recovery kicks in, while those who are hardest to help remain behind, which drives up the average duration of unemployment. But long-term unemployment is also self-sustaining: the longer someone has been out of work, the harder it becomes to help that person back into work<sup>67</sup> – which raises the risk of an increase in structural unemployment – and there is some indication that this may already have occurred in Portugal (see Box 13). An additional concern about the rise in long-term unemployment is that it has affected some groups more than others: at the end of 2013, two thirds of the low-skilled unemployed had been out of a job for a year or over – which points to the importance of maintaining (and adapting) the skills of the low-skilled while they are out of work. Chapter 3 delves deeper into the importance of skills investment for improving labour market outcomes in Portugal.

Figure 24. The incidence long-term unemployment, 2000 to Q3 2015

Proportion of the unemployed who have been out of a job for one year or over

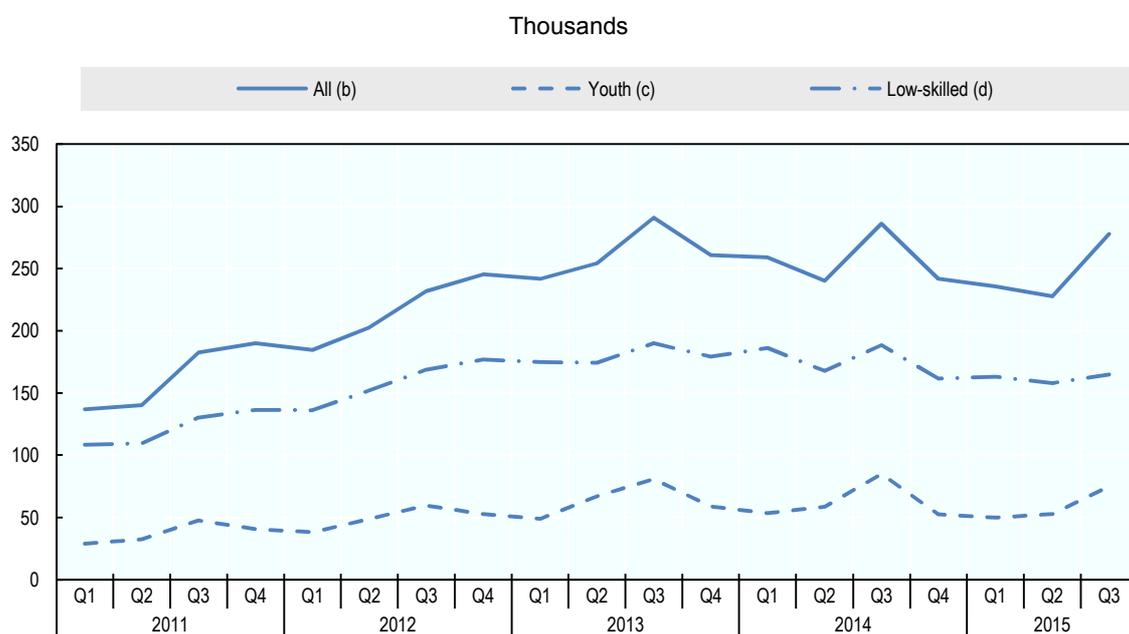

Source: OECD Employment Database.

The recent rise in long-term unemployment is not something that is unique to Portugal, however. Across the OECD, the incidence of long-term unemployment is up by 24% since 2007 (compared to 26% in Portugal). Addressing this high rate of long-term unemployment remains a key challenge for policy makers going forward, since there is a danger that many in this group lose their skills and motivation or, worse even, become permanently disengaged from the labour market. Indeed, the increased risk of marginalisation among the unemployed may not only show up in the form of increased long-term

67. There may be several reasons for this. On the one hand, employers become less and less likely to hire an individual the longer he/she has been unemployed, which could either be a result of employer screening or of human capital depreciation. On the other hand, individuals themselves might become increasingly discouraged and lower their search effort.

unemployment, but also in the rate at which the unemployed are dropping out of the labour force altogether. Figure 25 shows the trend in marginally attached persons (i.e. persons out of the labour force who are willing to work and available for work, but are not actively seeking work). The total number of marginally attached persons in Portugal more than doubled between the first quarter of 2011<sup>68</sup> and the third quarter of 2013, when they totalled 290 000 individuals – most of whom (two in three) were low-skilled. Again, this points to the importance of strengthening skills policies in Portugal. The number of marginally attached persons has been on the decline since the end of 2013, with the exception of a temporary rise in the third quarter of 2014 and an increase in the final quarter of the sample (2015Q3). The most recent fluctuations are mainly driven by youth, with the number of low-skilled marginally attached workers remaining fairly constant.

Figure 25. Number of persons marginally attached to the labour force<sup>a</sup>, Q1 2011 to Q3 2015

### Box 13. Is structural unemployment rising in Portugal?

#### The non-accelerating inflation rate of unemployment (NAIRU) has risen

The concern with high levels of long-term unemployment is that some of it may turn structural as certain individuals become further and further removed from the labour market and find it increasingly difficult to return to work. Two measures tend to be used to assess whether a rise in structural unemployment is taking place. The first of these is the non-accelerating inflation rate of unemployment (NAIRU), which is a measure of the level of the unemployment rate that is consistent with a constant rate of inflation. Figure A shows not only that the NAIRU is significantly higher in Portugal than it is in most other OECD countries, but also that it has risen substantially over the period 2007-2014. The NAIRU has risen by 5.5 percentage points in Greece, 4.1 percentage points in Spain, and 3.1 percentage points in Portugal.

Figure A. The non-accelerating inflation rate of unemployment (NAIRU), 2007-2014

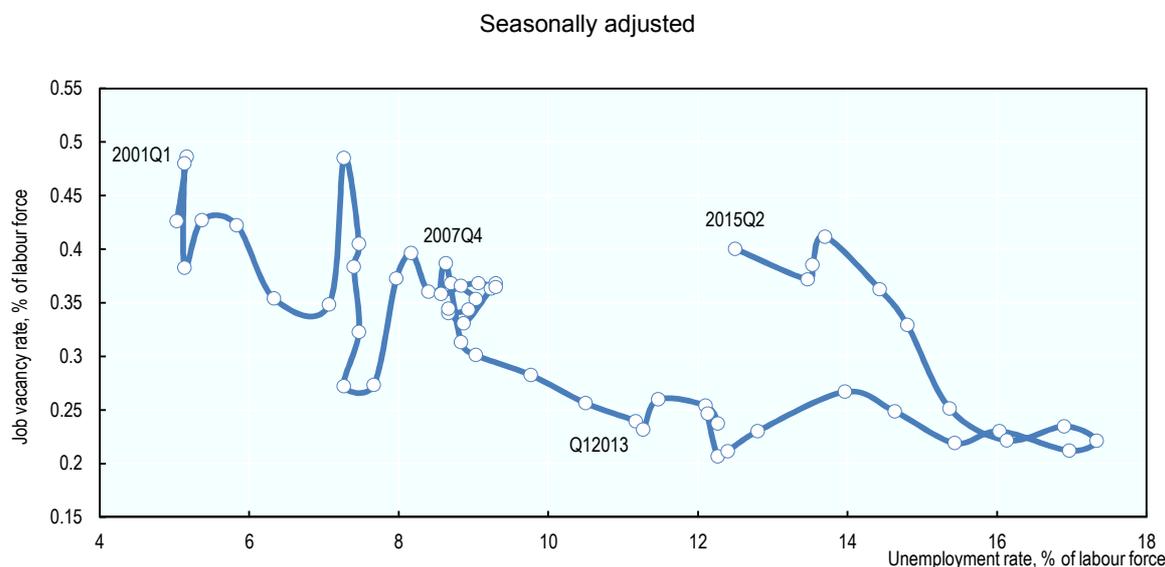

Source: OECD Economic Outlook Database.

#### There may be signs of a reduction in matching efficiency

An alternative way of assessing whether there has been an increase in the structural level of unemployment is to look at whether there has been a reduction in matching efficiency – i.e. whether a given level of vacancies is now associated with a higher level of unemployment, which would signal that it has become more difficult for unemployed jobseekers to find suitable job vacancies (and for firms to fill existing vacancies with qualified jobseekers). The relationship between job vacancies and the level of unemployment is also known as the Beveridge curve, which is downward sloping: as the number of vacancies increases, the unemployment rate falls (and vice versa). Figure B shows that there has been a definite outward shift in the Portuguese Beveridge curve as the crisis progressed (particularly from the beginning of 2013 onwards) – meaning that for a given level of vacancies, the unemployment rate is now higher. One difficulty with deciding whether this shift is permanent or not is that vacancies tend to respond more quickly to business-cycle conditions than the unemployment rate, so that instead of shifting out permanently, the Beveridge curve may simply trace out a counter-clockwise loop. Indeed, there is some indication from Figure B that the situation in Portugal has been improving since around mid-2014, with a fall in the unemployment rate for a vacancy rate which has remained more or less constant.

Box 13. Is structural unemployment rising in Portugal? (cont.)

**The labour market is still highly segmented, and is likely to remain so unless further reforms are undertaken**

*Despite the reforms of severance pay, employers still have strong incentives to hire on temporary contracts*

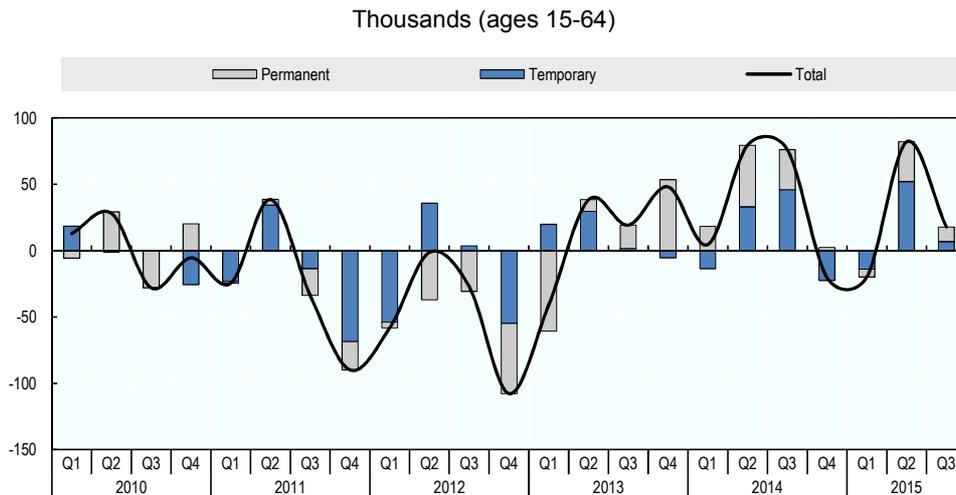

Prior to the crisis, the Portuguese labour market was characterised by a high degree of segmentation: in 2007, 22.3% of workers in dependent employment had a temporary contract, compared to just 12.2% across the OECD on average. The incidence of temporary employment in Portugal was even higher for certain groups, like young people (53.1%). While temporary employment in itself is not necessarily bad (indeed, some workers may prefer the flexibility that it offers), excessive use of such types of contracts can have an adverse impact on both equity and efficiency.<sup>69</sup> In particular, workers on these contracts often face a higher degree of job insecurity than employees on regular contracts, and firms may invest less in non-regular workers, which in turn may depress productivity growth (OECD, 2014b).

The high incidence of temporary employment in Portugal is to a large extent attributable to the important gap in employment protection legislation (EPL) between permanent and temporary contracts (see Chapter 1). Some of the labour market reforms in recent years have sought to reduce this gap. For example, severance pay on new permanent contracts is now lower than on temporary contracts, and there is

69. From the employer's point of view, temporary contracts offer more flexibility. There may also be some economic activity which would be difficult to carry out without such flexibility, e.g. in agriculture, tourism, retail and restaurants – which could be particularly important in the case of Portugal (Alves, 2015). Finally, there is evidence that employers use temporary contracts as a selection mechanism (screening device) into permanent contracts (Portugal and Varejão, 2010).

some evidence that this may have incentivised hiring on permanent contracts (see Box 2 in Chapter 1). Despite this, a large proportion (35%) of the employment growth between Q1 2013 and Q3 2015 has been on temporary contracts (Figure 26) and the share of temporary employment in total employment has barely budged (Figure 27). While the incidence of temporary employment in Portugal is down very slightly (to 21.5% in 2014), a similar reduction occurred on average across the OECD (to 11.1% in 2014) and will largely reflect the fact that workers on temporary contracts were more likely to lose their job during the crisis.

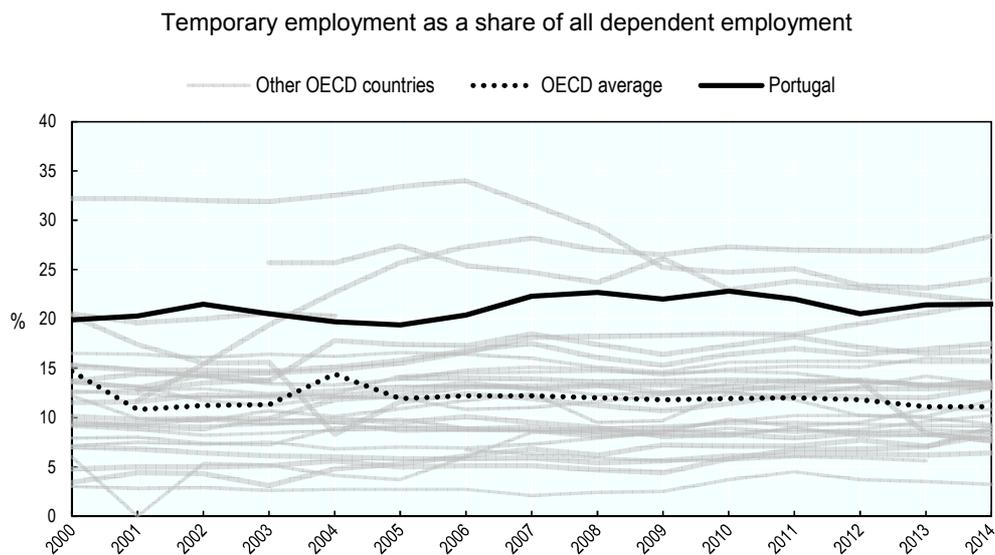

Figure 26. Change in employment by type of contract, Q1 2010-Q3 2015

Note: Because of a methodological change in the Portuguese Labour Force Survey, data prior to 2011 are not fully comparable with the more recent data. The new methodology results in higher levels of unemployment and inactivity compared to the methodology used prior to 2011. For detailed information, see Statistics Portugal (2011).

Source: Eurostat.

Figure 27. Incidence of temporary employment, 2000-2014

Source: OECD Employment Database.

There are several reasons why one should expect the incidence of temporary contracts in Portugal to remain high, particularly in the short-run. The first of these is that, while the reforms significantly reduced severance pay on new contracts, existing severance pay entitlements were largely preserved so that there is unlikely to be any immediate effect of the reform on firing behaviour (and evidence in support of this was presented in Chapter 1). Secondly (and most importantly), the procedural requirements for firing a worker on permanent contracts remain significantly more demanding than those for workers on temporary contracts, and so the reduction in severance pay may actually not have made much difference to employers. The third reason why there may have been little movement in the share of temporary employment over the period analysed in this report is that, on two separate occasions, employers were allowed to temporarily extend the duration of fixed-term contracts as a crisis-related measure. Finally, as long as employers in Portugal face downward wage rigidity, temporary contracts will remain a key source of flexibility, and so employers will continue hiring on temporary contracts as long as this gap in employment protection legislation between the two types of contracts persists. This last reason may be particularly relevant in the present economic climate: with a weak and hesitant recovery employers will remain uncertain about the future and therefore unwilling to offer workers the promise of a permanent contract.

***The share of self-employed in total employment has fallen***

Another facet of labour market segmentation in Portugal is the high prevalence of dependent self-employment. While specific data are not available to assess the extent of this problem (or how it has evolved over the crisis), data from Eurostat (based on the Portuguese Labour Force Survey) show that, at the beginning of 2008, nearly one in five persons in employment was self-employed (19.3%) – 13.6% without employees and 5.6% with (Figure 28). A significant, but declining, share of the self-employed without employees are working in the agricultural sector. Since the end of 2013, there has been a fall in the share of self-employed which is driven largely by a decrease in the share of self-employed without employees (from 12.1% in Q3 2013 to 9.8% in Q3 of 2015).<sup>70</sup> This fall coincides with the introduction of new powers of the labour inspectorate (ACT) to clamp down on false self-employment. However, it occurs primarily in the agricultural sector. It also comes at the same time as the economy starts moving out of recession and could partly reflect individuals who had taken up self-employment during the crisis as a survival mechanism and are now moving back into regular jobs.<sup>71</sup>

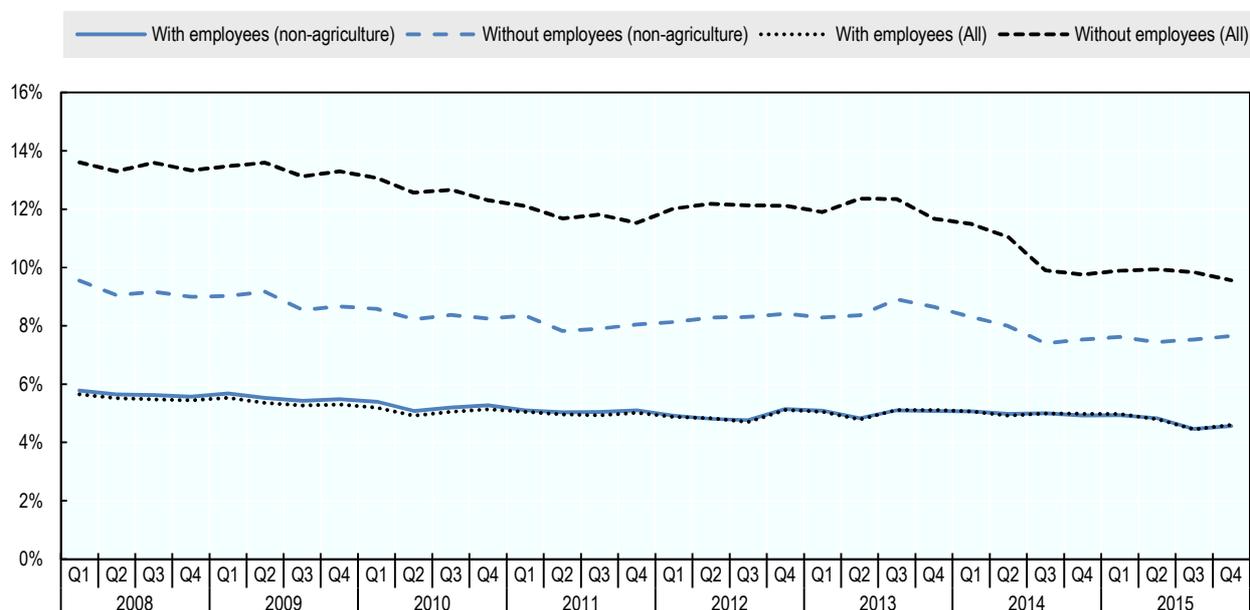

---

70. Note that the fall in self-employment occurs both for individuals active in the private and in the public sector (although it is slightly more marked in the former).

71. Martins (2016b) argues that the reduction in severance pay on new employees encouraged firms to hire employees instead of contractors.

Figure 28. Trends in self-employment, with and without employees, 2008-2015

Self-employed persons aged 15 years and older as a share of total employment

Note: Because of a methodological change in the Portuguese Labour Force Survey, data prior to 2011 are not fully comparable with the more recent data. The new methodology results in higher levels of unemployment and inactivity compared to the methodology used prior to 2011. For detailed information, see Statistics Portugal (2011).

**There were some improvements in competitiveness during the crisis, but this trend might have started reversing again**

### *Unit labour costs fell significantly in 2011 and 2012*

One major obstacle to achieving higher and more sustainable growth rates in Portugal is its low external competitiveness (OECD, 2014c; IMF, 2015). In most quarters between 2002 and the start of the crisis, unit labour costs (ULCs)<sup>72</sup> in Portugal increased faster than the OECD average (Panel A of 29), while productivity rose less fast than the OECD average and, in some quarters, even fell (Panel C of Figure 29). Throughout this period, rises in labour compensation tended to exceed gains in productivity, leading to a gradual deterioration of Portugal's external competitiveness. Part of the labour market reforms and interventions over the period 2011-2015 (e.g. changes to collective bargaining arrangements, the freeze in extensions as well as in the minimum wage, cuts in overtime compensation, etc.) were targeted at reversing this trend – with some success. As shown in Panel A of Figure 29, there was a fall in ULCs in Portugal in 2010, but especially in 2011 and 2012, with some further falls in 2014. As shown by Panel B of Figure 29, this was related primarily to falls in labour compensation per person employed.

72. Unit labour costs (ULC) are a commonly-used measure of competitiveness, and are obtained as the ratio between total labour compensation per unit of labour input and labour productivity. Two important caveats need to be mentioned about the use of ULCs as a measure of competitiveness. First, they are not a comprehensive measure of competitiveness, but just a reflection of cost competitiveness. Second, ULCs deal exclusively with the cost of labour which, though important, should also be considered in relation to changes in the cost of capital. However, because of problems of international consistency of data, it is usual to take indices of unit labour costs rather than total costs.

### *The fall in unit labour costs was larger in the public than in the private sector*

The falls in ULCs and compensation per person employed in Portugal were more marked in the public than in the private sector (Figure 30). Compensation in the public sector rose steadily over the period 2007-2009 (at a higher pace than in the private sector). However, this trend started reversing in 2011 (coinciding with the cuts in wages of civil servants earning more than EUR 1 500), and turned into a very significant drop in ULCs and labour compensation at the start of 2012 (when cuts in 13<sup>th</sup> and 14<sup>th</sup> monthly payments were implemented). In 2013, this fall was entirely reversed with the ruling of the Constitutional Court that the cuts in bonuses were unconstitutional. A similar pattern can be observed in 2014, when the Budget Law introduced new cuts to the wages of public sector workers, which were again declared unconstitutional later that year. These findings are consistent with the observations of INE (2013, 2014) that the overall decline in ULCs in 2011 and 2012 was largely driven by falling general government wages (through the non-payment of holiday and Christmas bonuses to civil servants), while the rise in 2013 was associated with the reinstatement of the bonuses in general government.

### *A high level of wage rigidity continues to threaten Portuguese competitiveness*

When looking at the non-agricultural business sector (excluding real estate), there has been a gradual but continuous decline in ULCs over the period 2009-2012 (Panel B of Figure 30). While there were some falls in labour compensation per hour worked in 2011 as well as in 2013, most of the fall in ULCs was driven by productivity gains<sup>73</sup> in the wake of job cuts.<sup>74</sup> Box 14 offers a more detailed look at the evolution of wages in the private non-agricultural business sector (excluding real estate) over the period 2010-2014. It shows how government policies helped achieve wage moderation during the crisis, with around one in two workers experiencing real falls in their base wage in each year over the period 2010-2014. That being said, these real falls were relatively modest and affected job movers in particular. At the same time, the evidence suggests a considerable amount of nominal wage rigidity in the Portuguese economy, with around three quarters of workers having had their base wages frozen in both 2012 and 2013.<sup>75</sup> Such wage rigidity (driven by the legal prohibition to cut nominal base wages) is likely to continue to harm Portuguese competitiveness in years to come if inflation remains low – unless there is a significant strengthening in productivity growth.<sup>76,77</sup> The evidence presented in Box 14 further suggests that, with the exception of a real fall in 2011, “other” wage components kept on rising both in nominal as well as in real terms, and that the reductions in overtime pay, while significant (particularly in 2012), represent only a minute share of the average wage bill per employee.

73. Leal and Martins (2015) argue that there is a relatively strong relationship over the period 2002 to 2014 between nominal wage increases stipulated in collective wage agreements and the percentage change in average compensation per worker – suggesting that moderate wage increases in collective agreements during the crisis contributed to the fall in unit labour costs by reining in increases in average compensation per worker.

74. An alternative possibility is that firms adjust in their effort margins during recessions, requiring workers to produce more than in better times (Card and Mas, 2016).

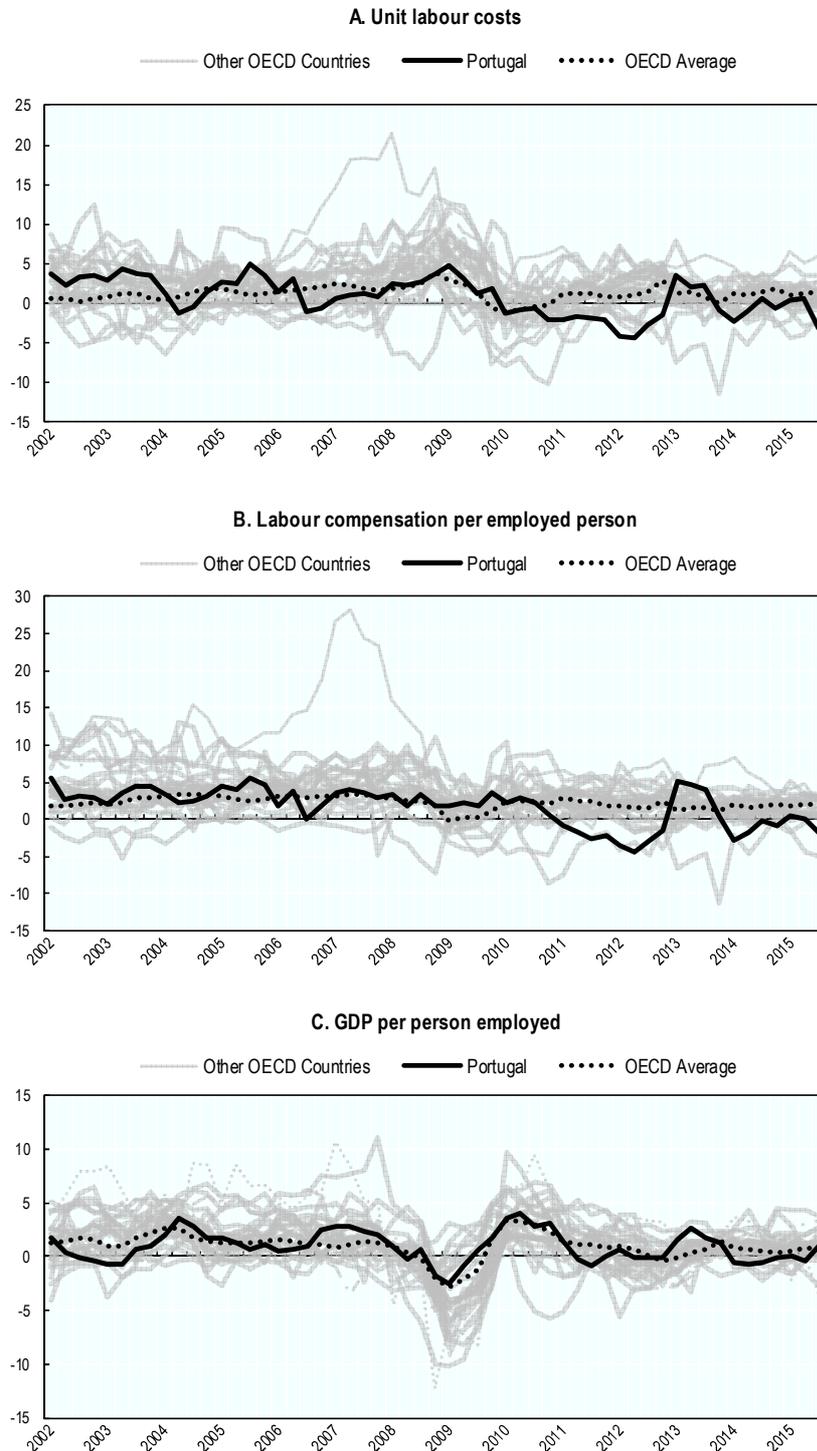

75. These findings are consistent with many published studies for Portugal, including Duarte (2008), Portugal, Carneiro and Guimarães (2010), Carneiro, Portugal and Varejão (2014).

76. Wage rigidity in Portugal has been found to be a greater problem for small firms (Duarte, 2008) and may be part of the reason why those firms also exhibit higher rates of turnover (Centeno, Machado and Novo, 2007). That being said, wage rigidity tends to be higher in the services and construction sectors than in the manufacturing sector.

77. Another possible consequence of high nominal wage rigidity is that wage growth in the Portuguese economy is likely to remain very low in the short-run because of “pent-up wage inflation” (Martins and Portugal, 2014).

**Box 14. Wages in the private sector during the crisis: Wage moderation and nominal wage rigidity**

The significant employment losses observed in Portugal during the crisis can, according to some commentators, be blamed largely on a high level of (nominal) wage rigidity which, combined with an important share of temporary workers, makes it easier for employers to adjust to business cycle fluctuations by reducing headcounts than by revising wages downwards. Indeed, when Portuguese employers are asked how they cut costs in response to negative shocks, 72% say they reduce their workforce – by far the most common strategy cited (Dia, Marques and Martins, 2012).

A number of measures were taken by the government to try and achieve wage moderation during the crisis: the minimum wage was frozen, the number of extensions of collective agreements was kept in check, and significant reductions in overtime pay were brought in.

Against this background, this box uses the *Quadros de Pessoal* data<sup>1</sup> to analyse the behaviour of (nominal and real) wages in the private non-agricultural business sector (excluding real estate) during the crisis and, where possible, breaks this down by wage component. The findings confirm a high degree of downward rigidity in nominal base wages in Portugal: a large number of employees had their base wages frozen during the crisis. Over the period 2010-2013, nominal wage growth was modest in the business sector, and wages fell in real terms. There is evidence also of a significant drop in overtime pay – although this only represents a very small proportion of firms' total wage bill.

**Nominal wage growth was modest, and there were some falls in real wages**

Average hourly wages (in nominal terms) continued to rise modestly in 2011 (+1.0%) and 2012 (+1.7%), but fell slightly in 2013 (-0.5%) and 2014 (-0.3%) – Table A. The fall in 2013 and 2014 was largely due to the substitution of higher-paid with lower-paid workers.<sup>2</sup> Indeed, when looking only at workers who remained employed between two consecutive years, nominal (hourly) wages rose in each year (by 1.9%, 1.4%, 1.6% and 2.5%, respectively). In real terms, average hourly wages fell in each year over this period (although there was real wage growth in 2013 and 2014 for workers who remained employed).

**Table A. Average nominal and real wage growth of private sector employees in Portugal, 2010-2014**

## Change in hourly wages

	Year	All workers				People remaining in employment			
		Total	Base	Overtime	Other	Total	Base	Overtime	Other
Nominal	2011	1.0%	0.7%	2.1%	1.4%	1.9%	1.5%	3.2%	3.2%
	2012	1.7%	1.3%	-22.0%	4.2%	1.4%	1.1%	-22.1%	4.5%
	2013	-0.5%	-0.6%	-2.5%	1.2%	1.6%	1.2%	-0.9%	4.1%
	2014	-0.3%	-0.6%	0.4%	0.3%	2.5%	1.9%	3.2%	4.3%
Real	2011	-2.7%	-3.0%	-1.6%	-2.3%	-1.8%	-2.2%	-0.5%	-0.5%
	2012	-1.0%	-1.4%	-24.7%	1.5%	-1.3%	-1.6%	-24.8%	1.8%
	2013	-0.8%	-0.9%	-2.8%	1.0%	1.4%	1.0%	-1.2%	3.8%
	2014	-0.1%	-0.3%	0.7%	0.6%	2.7%	2.2%	3.5%	4.5%

*Note:* Changes in overtime and other pay are estimated only for employees who receive such payments. Hourly overtime payments are obtained by dividing total overtime pay by the number of overtime hours worked. Hourly "other" payments are obtained by dividing total other pay by the number of regular hours worked. People remaining in employment are defined as workers who are employed in two consecutive years.

Box 14. **Wages in the private sector during the crisis: Wage moderation and nominal wage rigidity** (cont.)

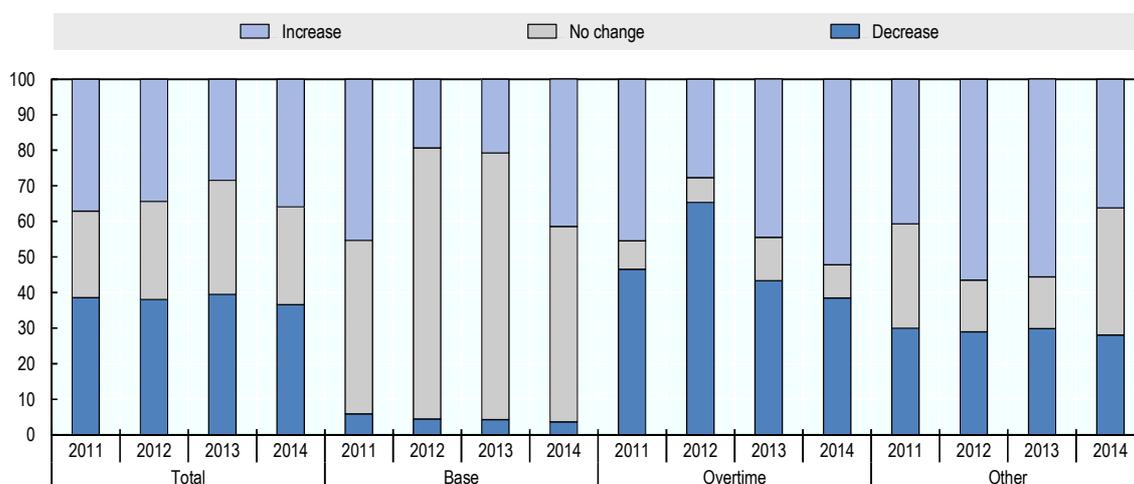

**The base wages of a large proportion of workers were frozen**

Table A also breaks down the evolution of wages by wage component: base wages, compensation for overtime, and other wage components. Changes in base wages were closely aligned to changes in total wages, although they grew even less. Despite the severity of the crisis, the average nominal base wage of workers who kept their job in consecutive years did not fall. Such cuts are in fact forbidden by Portuguese law. Given this constraint, employers still have the option in times of crisis to freeze base wages in the hope that inflation will bring real wages down. This was indeed a very common strategy used by employers in Portugal during the crisis. Looking at employees in the non-agricultural private business sector who remained employed in two consecutive years, Figure A shows that 49% had their base wages frozen in 2011, rising to 76% in 2012 and 75% in 2013. In 2014 the share of workers with constant base wages fell to 55%. These figures are substantially larger than what was observed in countries like the United States (where around 4% of job stayers had their nominal wages frozen) and the United Kingdom (where only around 9% of job stayers had zero nominal wage change) – see Elsby, Shin and Solon (2016). This indicates a substantial element of nominal wage rigidity in the Portuguese labour market.<sup>3</sup> The freezing of nominal base wages by Portuguese employers will have been made easier by government policy during the period, including the freezing of the minimum wage, as well as the reduction in extensions of collective agreements.

As in the case of total wages, however, Table A shows that base wages fell in real terms throughout the period (although workers who remained employed saw a real wage increase in 2013 and 2014). Figure B shows that around one out of two workers saw their base wage fall in real terms in each year.

Figure A. **Proportion of workers who experienced nominal hourly wage increases, freezes and falls, 2010-2014**

As a proportion of workers who remained employed in two consecutive years

Note: Changes in overtime and other pay are estimated only for employees who receive such payments in at least one of period  $t$  or  $t+1$ . Hourly overtime payments are obtained by dividing total overtime pay by the number of overtime hours worked. Hourly "other" payments are obtained by dividing total other pay by the number of regular hours worked. Wages are assumed to exhibit "no change" if wages at time  $t$  and  $t+1$  do not differ more than 1%.

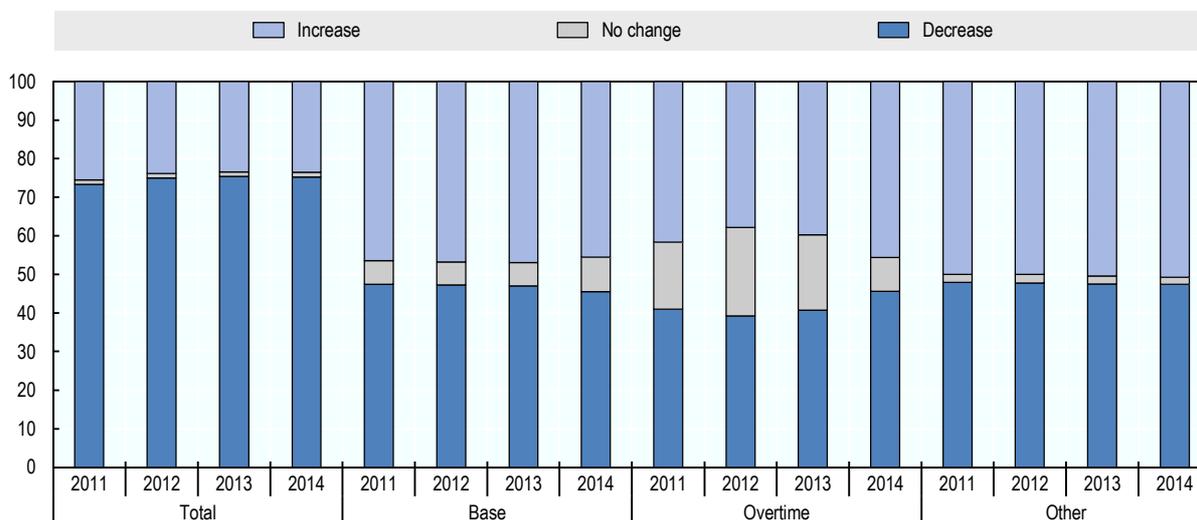

Source: OECD analysis based on the *Quadros de Pessoal*.

While Figure A indicates that between 4 and 6% of workers who remained employed had a reduction in their hourly nominal base wage each year, in around 99% of these cases this was accompanied by a change of employer. Note that these percentages are very small compared to the proportion of workers who suffered nominal wage cuts in the United States and the United Kingdom. In the United Kingdom, nearly one in four job stayers experienced a nominal wage cut over the periods 2009-2010 and 2011-2012, while in the United States nearly one in four job stayers experienced a nominal wage cut of at least 0.5% (Elsby, Shin and Solon, 2016).

## Box 14. Wages in the private sector during the crisis: Wage moderation and nominal wage rigidity (cont.)

Figure B. Proportion of workers who experienced real hourly wage increases, freezes and falls, 2010-2014

As a proportion of workers who remained employed in two consecutive years

Note: Changes in overtime and other pay are estimated only for employees who receive such payments in at least one of period t or t+1. Hourly overtime payments are obtained by dividing total overtime pay by the number of overtime hours worked. Hourly “other” payments are obtained by dividing total other pay by the number of regular hours worked. Wages are assumed to exhibit “no change” if wages at time t and t+1 do not differ more than 1%.

Source: OECD analysis based on the *Quadros de Pessoal*.

### There were significant reductions in overtime pay

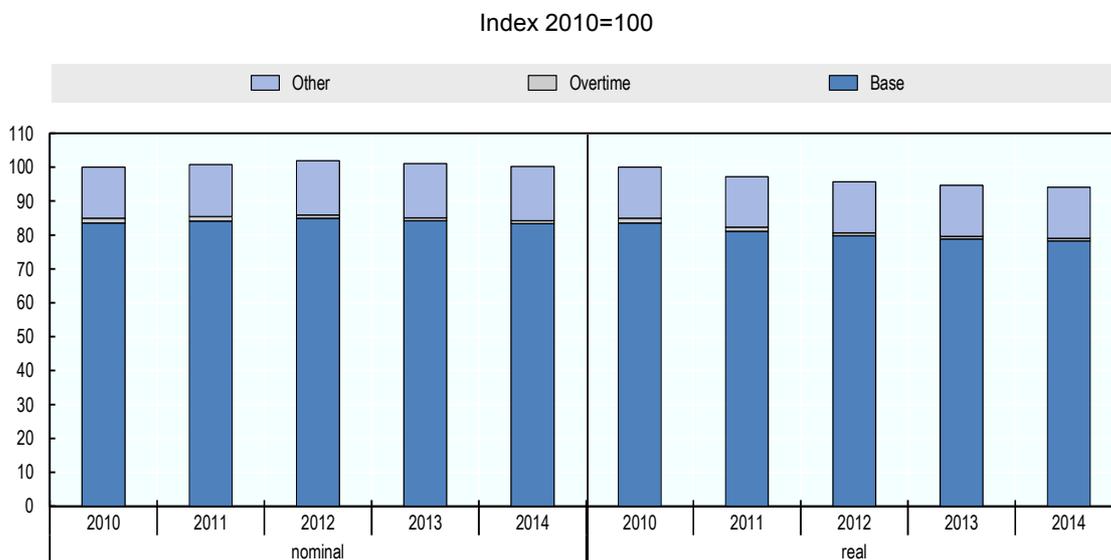

While Portuguese law forbids reductions in the base wage, other wage components can be adjusted. Indeed, Figure A shows that, each year, more than a quarter of workers had reductions in their “other” hourly wages from one year to the next. On average, however, and with the exception of a real fall in 2011, these “other” wages kept on rising both in nominal as well as in real terms (Table A).

Figure A also shows reductions in hourly overtime pay: in 2011, 47% of workers (who worked overtime and remained employed) experienced a reduction in the hourly rate for overtime pay, rising to 65% in 2012 (when the government reduced the rates for overtime work by half), and back to 43% in 2013 and 39% in 2014. Table A shows that the average reduction in hourly overtime pay was 22% in 2012. These figures suggest that the new law had a significant impact on overtime pay (and may have had an important impact on the incomes of some workers). However, from the perspective of firms, this measure will only have had a marginal impact. Indeed, for firms paying overtime to at least one of their employees, the share of overtime pay in the total wage bill was only around 5.2%. Moreover, only about 3.5% of all firms paid overtime to one or more of their employees.

While these findings confirm that firms can, and do, reduce their wage costs during times of crisis by adjusting overtime and other pay,<sup>4</sup> they also show that the impact of these adjustments on total wages were relatively limited. Figure C shows how the average wage paid by a Portuguese firm (estimated as the average wage bill per employee) evolved over the period 2010-2014, sub-divided into its various components. The average nominal wage bill continued to increase modestly in both 2011 and 2012. While there were some small falls in both 2013 and 2014, the total nominal wage bill in 2014 was still the same as in 2010. Despite the important falls in overtime pay discussed above, Figure C shows that these will have made very little difference to firms in practice. Figure C also confirms how, in real terms, the average wage bill per employee fell in each year.

## Box 14. Wages in the private sector during the crisis: Wage moderation and nominal wage rigidity (cont.)

Figure C. Evolution of average wage bill per employee, by wage component, 2010-2014

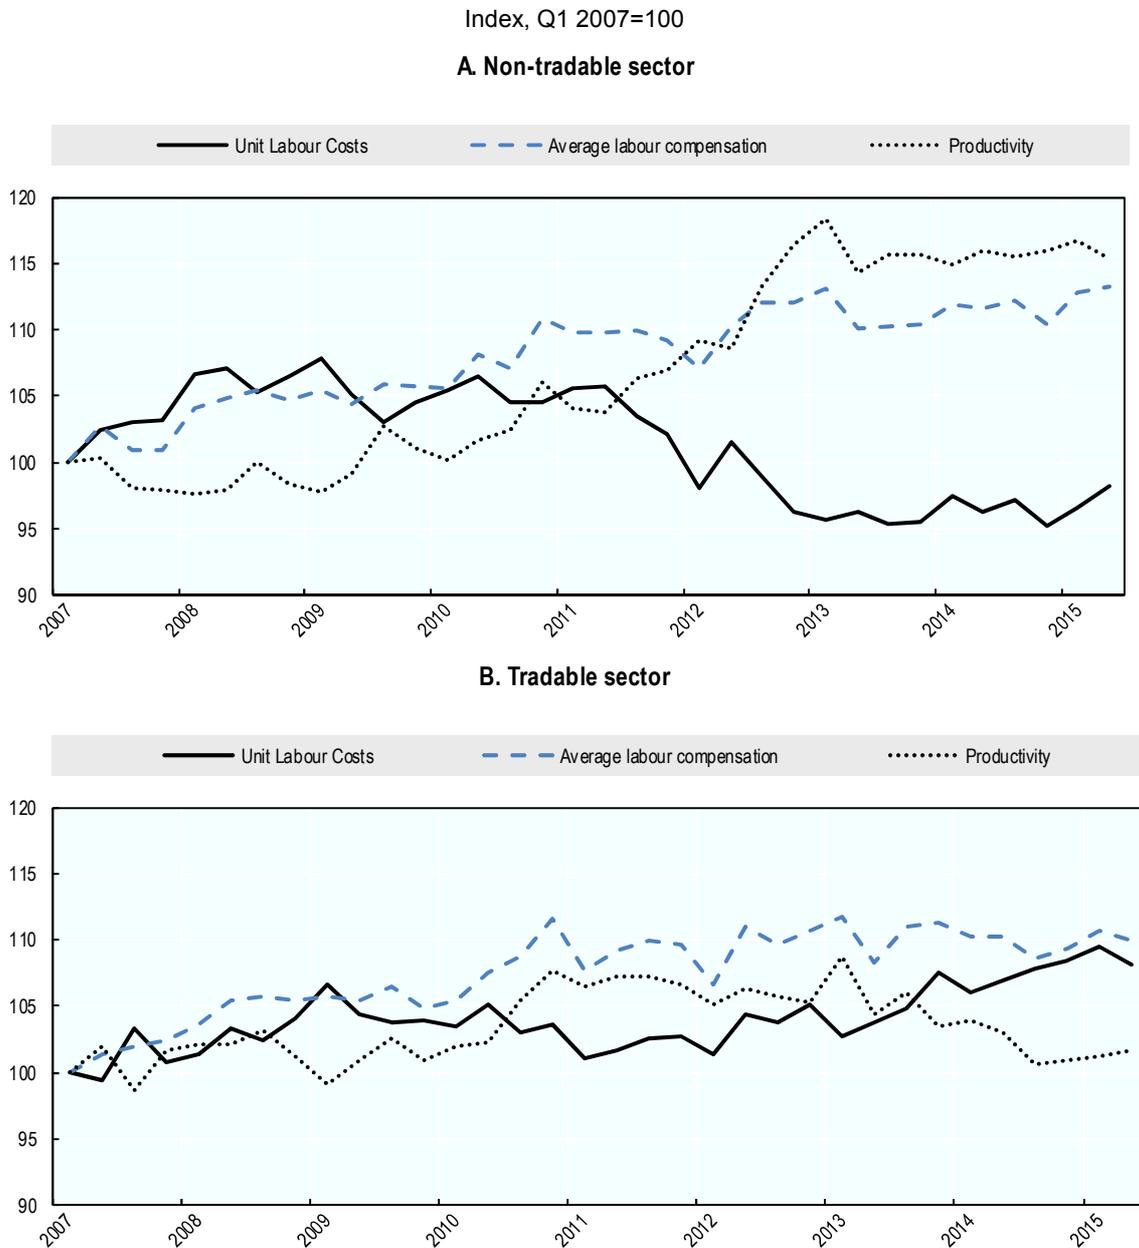

Source: OECD analysis based on the *Quadros de Pessoal*.

1. The *Quadros de Pessoal* is a compulsory census of all non-public firms with at least one employee which is carried out in October each year. The administrative nature of the data ensures a high degree of coverage and reliability, and unique employer and employee identifiers allow the data to be linked from one year to the next.
2. According to the survey discussed in Dias, Marques and Martins (2012), 30% of firms said they hired workers on lower wages than those that had just left in order to cut costs when faced with an adverse shock. Cyclicalities in hiring wages in Portugal was also documented by Martins, Solon and Thomas (2012).
3. Portugal, Carneiro and Guimarães (2010) noted that when Portugal joined the Euro in 1999, the cyclical elasticity of real wages was significantly reduced.
4. A related measure identified by Dias, Marques and Martins (2012) which firms use to cut costs is the less frequent use of promotions. The *Quadros de Pessoal* data indicate that the share of workers who received a promotion nearly halved from 6.2% in 2010 to 3.8% in 2014.

***There has been a slight rebalancing of labour resources from the non-tradable to the tradable sector***

Within the private sector, it is important to distinguish further between the tradable and the non-tradable sectors, since it is the evolution of ULCs in the tradable sector that will matter most to competitiveness. This distinction is made in Figure 31 and shows that the decline in ULCs in Portugal was larger in the non-tradable than in the tradable sector, and that the latter was particularly marked in the years 2011 and 2012. ULCs in the tradable sector also fell somewhat between 2009 and 2012, after which they started increasing again as productivity fell. By contrast, there was a rise in productivity in the non-tradable sector which was partly driven by employment losses, which were larger in the non-tradable than in the tradable sector (see Figure 32). These differences in employment losses (as well as somewhat greater employment growth in the tradable sector) have contributed to the slight rebalancing that happened between the two sectors: the tradable sector's share of business sector employment increased from around 43% between 2005 and 2007 to 47% in the first half of 2015. However, despite this rebalancing of labour resources to the tradable sector, the latter's share remains relatively low in comparison to other European countries.

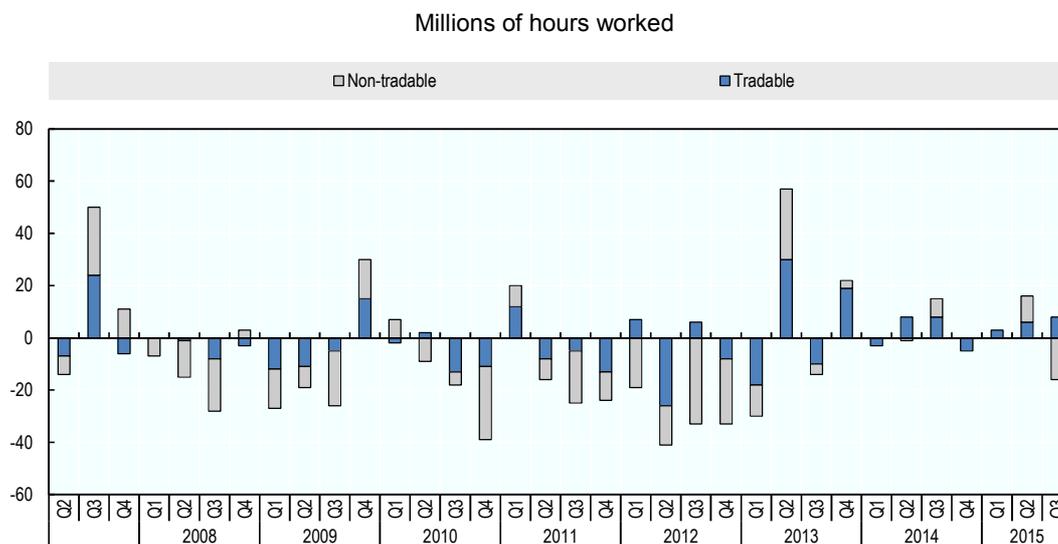

Figure 31. Evolution of quarterly unit labour costs and its components, tradable versus non-tradable sectors, Q1 2007-Q2 2015, Portugal

### High unemployment has resulted in rising poverty

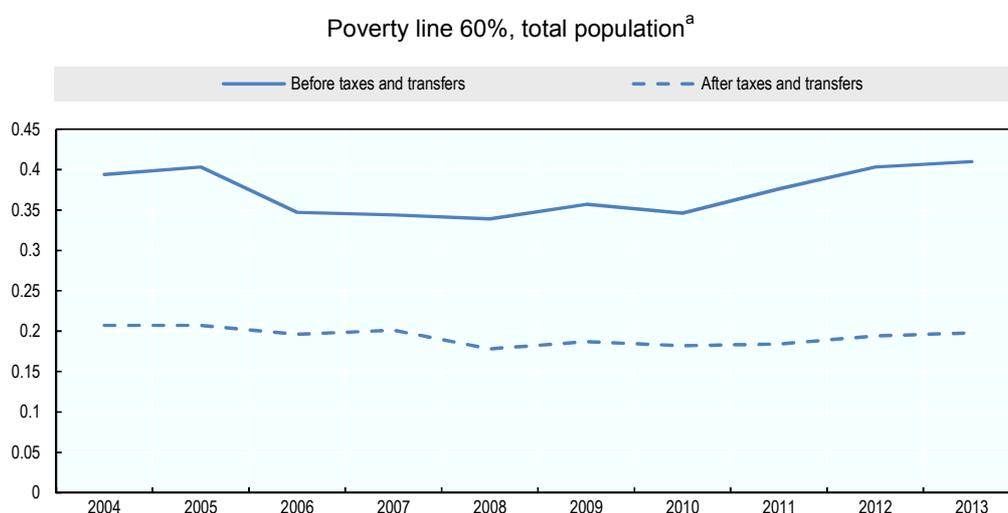

The economic crisis has halted a long-term gradual decline in poverty and, from 2011 onwards, the proportion of individuals living in households with an income below 60% of the median started increasing again (Figure 33). The rise in unemployment has been one of the main contributing factors to this upsurge in poverty (over 40% of the unemployed lived in poverty in 2012), although there is also a substantial share of in-work poverty (10.5% of the employed in 2012).<sup>78</sup>

As Figure 34 indicates, the Portuguese tax-benefit system does a decent job at alleviating poverty: the rise in poverty after taking taxes and transfers is substantially less marked than when these are not taken into account. This is because the tax system in Portugal is very progressive, while transfer payments tend to reduce poverty in a fairly efficient way (Arnold and Farinha Rodrigues, 2015). That being said, it is clear that some other OECD countries achieve even greater reductions in poverty through taxes and transfers, suggesting that there is ample room for improvement in Portugal. This is all the more necessary given that reforms undertaken during the crisis period have resulted in substantial losses in disposable income for the lowest income groups (Avram et al., 2012). In particular, the reduction in generosity of the *Rendimento Social de Inserção* (RSI – social assistance) (the access threshold was lowered and the

78. Analysis carried out for this project using the EU tax-benefit microsimulation model (EUROMOD) model suggests that the increase in poverty between 2007 and 2015 could not be attributed to changes in direct personal taxes (income tax and social contributions) and cash benefits. Simulations applying the 2015 tax-benefit rules on the 2007 population suggest that overall poverty would have been lower in 2007 than it was under the 2007 policy rules. There are some differences by population sub-groups, however. While poverty among adults and the elderly in 2007 would have been lower under the 2015 system, child poverty would have been higher. It is worth noting that the simulations carried out are static and do not take account of any possible behavioural responses to policy changes. It assumes, for example, that the labour supply would not change in response to changes in taxes and benefits.

equivalence scale was made more stringent) resulted in a significant decline in the number of beneficiaries, penalising families with children in particular.<sup>79</sup> Since most of the individuals affected were already below the poverty line, these reforms have not impacted much on measured poverty itself. However, they have made the poor even poorer, with very little fiscal saving.

A detailed analysis of how poverty-reducing improvements in the tax-benefit system might be achieved was recently carried out by Arnold and Farinha Rodrigues (2015) and their main recommendations are as follows:

- Given that social expenditures in Portugal are already quite high and that there is limited fiscal space, the priority should be on making existing redistributive policies more efficient as opposed to spending more.
- The benefit system should be rebalanced away from elderly people (who currently receive a disproportionate share of benefit expenditure) and towards families with children instead.
- The efficiency of the benefit system could be enhanced by eliminating benefit overlaps and improving means-testing.
- The RSI threshold should be raised so that more individuals benefit, and more resources should be targeted on children by giving them a more generous weight in the calculation of the benefit. Similarly, raising the means-tested child benefits would be an efficient way of reducing child poverty.

79. The new XXI Constitutional Government established on 26 November 2015 has reversed part of the cuts in generosity of the RSI, which is a welcome development. In particular, the government re-established the weights for dependants and children to their original levels, which was important given the concentration of poverty among children. The reversal of the cut in the income threshold is being done in a phased manner. In 2016, 25% of the cut was reversed; in 2017, another 25% will be restored; and so forth, until the level prior to the cut is fully reinstated in 2019.

### Increased labour market insecurity has led to a fall in job quality

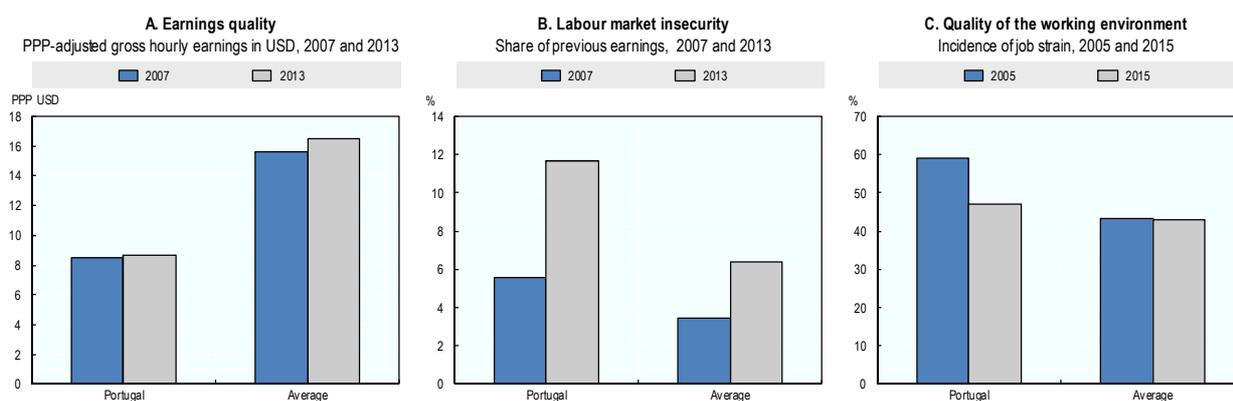

While having a job is an important determinant of well-being, the quality of that job matters as well. At various points throughout this report aspects of job quality in Portugal have been discussed, including: earnings, the risk of unemployment and the generosity of unemployment benefits. However these, as well as other measures of job quality, can be usefully summarised by the OECD's job quality framework (OECD, 2014b) which focuses on the outcomes for workers in three broad and complementary areas that are most important for their well-being:

- *Earnings quality*, which captures the extent to which earnings contribute to workers' well-being in terms of average earnings and their distribution across the workforce.
- *Labour market security*, which captures those aspects of economic security related to the risks of job loss and its economic cost for workers. It is defined by the risks of unemployment and benefits received in case of unemployment.
- *The quality of the working environment*, which captures non-economic aspects of jobs including the nature and content of the work performed, working-time arrangements and workplace relationships. These are measured as the incidence of job strain characterised as high job demands with low job resources.

Across all three dimensions of job quality, Portugal performs worse than the OECD average – and this is true both before and after the financial crisis (Figure 35). The evolution of job quality over the crisis is mixed in Portugal. The greatest negative impact has been on labour market security, which reflects the

large upsurge in unemployment. At the same time, earnings quality has more or less stagnated – which is consistent with the analysis presented earlier on in this chapter. For those who remained employed, however, there has been a marked decrease in the incidence of job strain and, therefore, an increase in the quality of the working environment. This will partly reflect a selection effect, given that those in worse quality employment were more likely to have lost their job during the crisis.

Figure 35. Job quality in Portugal and the OECD, 2005-2015

Note: The average excludes: Turkey, Slovenia and Luxembourg in the case of earnings quality; Chile in the case of labour market insecurity; and Australia, Canada, Chile, Iceland, Israel, Japan, Korea, Mexico, New Zealand, Norway, Switzerland, Turkey and the United States in the case of quality of the working environment.

### CHAPTER 3

## POLICY PRIORITIES FOR ACHIEVING BETTER LABOUR MARKET OUTCOMES IN PORTUGAL

This final chapter offers some thoughts on the road that lies ahead. The labour market reforms carried out over the past few years in Portugal were comprehensive and, as argued in this report, it will take time for their full effects to become both visible and entirely understood. In this sense, the present report should be seen only as a preliminary assessment of those reforms. That being said, it is possible, even at this stage, to make some observations about key policy priorities for the future. While most of these will require further reforms of labour market institutions, policies and practices, achieving higher levels of employment and greater inclusiveness in Portugal will also depend on factors that lie outside the realm of labour market policy. These include first and foremost the need to return to higher and more sustainable levels of growth, but also, amongst others: further investments in skills, product market and tax reforms, and improving the access that firms have to credit.

The statistical data for Israel are supplied by and under the responsibility of the relevant Israeli authorities. The use of such data by the OECD is without prejudice to the status of the Golan Heights, East Jerusalem and Israeli settlements in the West Bank under the terms of international law.

## Labour market policy: The road ahead

### *Employment protection legislation on permanent contracts should be further eased*

The EPL reforms described in Chapter 1 made it clear that Portugal, despite tremendous progress in recent years, remains the country in the OECD with the most stringent regulations around individual dismissal of workers on permanent contracts. Portuguese employers are therefore likely to continue to think twice before they hire a worker on a permanent contract, and may still prefer lower-cost and more flexible temporary contracts instead. Labour market duality is therefore likely to remain a distinctive feature of the Portuguese labour market in years to come, unless even more is done to reduce the gap in employment protection between the two types of contract. A comparative analysis with other OECD countries highlights a few areas where Portugal's legislation still stands out:

- First, *procedural requirements* in the case of individual dismissal of workers on permanent contracts remain high, including notification procedures and the delay involved before notice can start. Easing such requirements would not only bring Portugal's legislation more in line with that of other OECD countries, it would also help to narrow the gap with temporary contracts, where no such requirements are set.
- Second, while Portugal reduced severance pay in the case of fair dismissal, *compensation following unfair dismissal* remains amongst the highest in the OECD. The highest typical compensation (in terms of months of former pay) for unfair dismissal of an employee with 20 years of job tenure can be found in: Sweden (32 months), Italy (estimated at 21 months), China (20 months), Portugal (17.5 months) and France (16 months). These amounts are particularly high if compared with the OECD average, which is close to six months.
- Last but not least, Portugal remains one of the few countries (along with Austria, the Czech Republic and Korea) where *reinstatement* after unfair dismissal is almost always granted or offered to the worker (except in cases of procedural irregularity). OECD (2013b) showed that restricting the possibility of reinstatement has been one of the main policy interventions across OECD countries since 2008 and also that such trend is justified on the basis that reinstatement is one of the aspects of EPL which most affects gross worker flows, and job-to-job flows in particular.

One fundamental barrier to further lowering EPL on permanent contracts in Portugal is Article 53 of the Portuguese Constitution which guarantees “job security” and prohibits dismissals without “just cause”, yet fails to define what the latter means.<sup>80</sup> A very conservative interpretation of this article has significantly restricted the definition of what constitutes a fair dismissal (i.e. disciplinary reasons) and has put the onus on the employer to prove that maintaining the work relationship is practically impossible. It is this narrow interpretation which has frustrated attempts to revise the definitions of fair dismissal during the recent reform period. This restrictive definition of what constitutes a fair dismissal significantly increases the risk of litigation for the employer (and of reinstatement and the payment of compensation) following the dismissal of a worker. It therefore impedes the efficient (re)allocation of labour resources.

Moving forward, it would therefore be particularly important to clarify the conditions under which companies can dismiss workers on permanent contracts for economic reasons. Such reforms were recently undertaken in both Spain and France. In Spain, since the 2012 labour market reform, a dismissal is always justified if the company faces a persistent decline (over three consecutive quarters) in revenues or ordinary income. In addition, and perhaps more importantly, the firm does not have to prove that the dismissal is essential for the future profitability of the firm (OECD, 2013b). In France, since the 2016 labour market

80. For a comprehensive discussion of the interpretation of Article 53 of the Portuguese Constitution, see Phalempin (2014).

reforms, a dismissal on economic grounds will be justified if sales or orders fall for: four consecutive quarters in comparison to those of the previous year for firms with 300 or more employees; three consecutive quarters for firms with at least 50 but fewer than 300 employees; two consecutive quarters for firms with at least 11 but fewer than 50 employees; and one quarter for firms with fewer than 11 employees.

In Portugal, clarifying the conditions under which employers can dismiss workers on permanent contracts for economic reasons would probably require a change to the Constitution (Article 53) – which might not be easy to achieve. Nevertheless, further reductions in employment protection legislation for workers on permanent contracts can still be achieved by: lightening the procedural requirements for dismissal, reducing the compensation following unfair dismissal, and lowering the probability of reinstatement. A pragmatic solution to achieve the latter objective could be modelled on the approach taken in Germany. While severance pay in Germany is not mandatory, most employers do offer it, and employees who accept this severance pay forego their right to go to court. In Portugal a similar system could be introduced whereby employees who are dismissed have a right to (ordinary) severance pay only if, within a certain time period, he/she does not bring the case to court. This approach would reduce some of the risk and uncertainty for the employer.

Labour market duality could also be reduced through other means – e.g. by making hiring on temporary contracts relatively more expensive than hiring on permanent contracts. This could be achieved by charging higher social security contributions on temporary contracts (as was done in Slovenia, France and Italy, for example). While this will likely help reduce labour market segmentation, there is a risk that higher labour costs would reduce employment, particularly for the more marginal workers (Cahuc et al., 2016). Therefore, one may wish to waive these higher social security contributions when firms hire marginal workers (e.g. low-skilled, youth and the long-term unemployed). Also, higher social security contributions on temporary contracts may pose a particular challenge for sectors that rely heavily on seasonal workers (e.g. agriculture and tourism).

The report has also argued that the system of severance pay in Portugal could be reformed further to emulate the one of Austria. In that system, workers accumulate rights to severance pay into individual savings accounts which are transferable from one employer to another, or can be transformed into a cash payment or annuity upon retirement. The advantage of this system is that it removes the disincentive to worker mobility inherent in systems where severance pay entitlements are strictly linked to the current employer. That being said, the advantages of increased portability will need to be carefully weighed against the additional cost of running such a scheme – particularly if it falls on employers.

A final observation relates to the direction of future reforms, which should be aimed primarily at reducing the stringency of employment protection legislation on permanent contracts, rather than on making hiring on temporary contracts more difficult and costly. Indeed, as pointed out in OECD (2014b), making hiring regulations on temporary contracts too restrictive might be counterproductive, by increasing perceptions of job insecurity for those workers who are unable to use non-regular contracts as a stepping-stone into open-ended ones. It is on the difficulty of firing permanent workers that Portugal stands out compared to other OECD countries, not on the difficulty of hiring temporary ones.

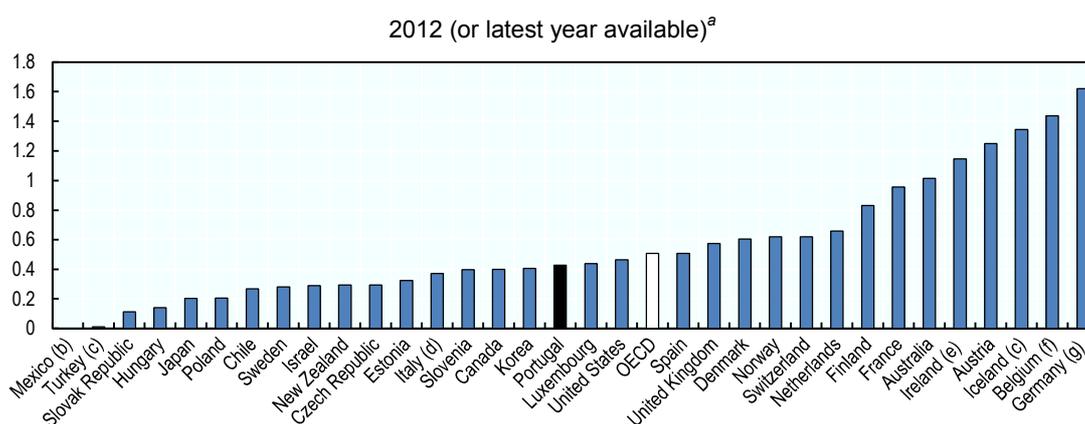

***Coverage of unemployment benefits should be increased, but their maximum duration further reduced***

The reforms of unemployment benefits in Portugal were a move in the right direction. Access to unemployment insurance was eased and coverage held up well despite a substantial increase in the number of unemployed (and, in particular, in the number of long-term unemployed and individuals with short contribution histories). In order to fight long-term unemployment, both the replacement rate of

unemployment insurance and the maximum duration of benefits were reduced, which brought the Portuguese system more in line with OECD norms.

Despite these positive steps, coverage of the unemployed in terms of unemployment insurance or assistance remains modest in Portugal compared to other OECD countries (Figure 36). In 2012, the ratio of beneficiaries to the number of unemployed stood at 0.43 in Portugal, compared to 0.52 across the OECD on average (and below the coverage rates for countries like Spain and the United States). Going forward, further improving coverage should be a priority for the Portuguese Government and a key challenge will be to cover young people and others with incomplete contribution records (e.g. those on non-regular employment contracts). Self-reported data from the EU-LFS suggest that, in 2013, fewer than 5% of unemployed youth in Portugal said they received benefits or assistance, compared to over 40% of adults. Another, related issue is that access to unemployment assistance in Portugal has been falling gradually over time because the means test threshold (80% of the IAS) has not been updated since 2009. Increasing this threshold would help raise the coverage of unemployment assistance in a targeted way. Finally, while those who are not (or no longer are) eligible for unemployment assistance may be eligible for the last-resort RSI income support, access to this benefit itself has reduced over time (see discussion at the end of Chapter 2).

Figure 36. Ratio of unemployment insurance/assistance beneficiaries to LFS unemployed, 2012

- 2011 for Chile, 2010 for Iceland.
- In 2012, there was no unemployment insurance or assistance in Mexico.
- In Turkey and Iceland, some programmes included in the total are partially missing. Consult the country note for details: <http://www.oecd.org/social/recipients.htm>.
- In Italy, recipients of the *Cassa Integrazione Guadagni* (CIG) are not included (even those who did not work at all).
- In Ireland, all recipients of unemployment benefit are included, even those who work very few hours.
- In Belgium, recipients of unemployment insurance aged over 65 are included.
- In Germany, the number of beneficiaries of unemployment assistance is usually expressed in terms of the number of family members that benefit (not just the unemployed individual). In order to make the estimates for Germany more comparable to those of the other OECD countries, the graph counts the number of families (and not family members) that receive unemployment assistance.

Notes: In some countries the ratio of beneficiaries to unemployed can exceed one because entitlements to unemployment assistance are not necessarily based on ILO definitions of unemployment. The OECD average is calculated assuming ratios of 1 in all those countries where they exceed 1.

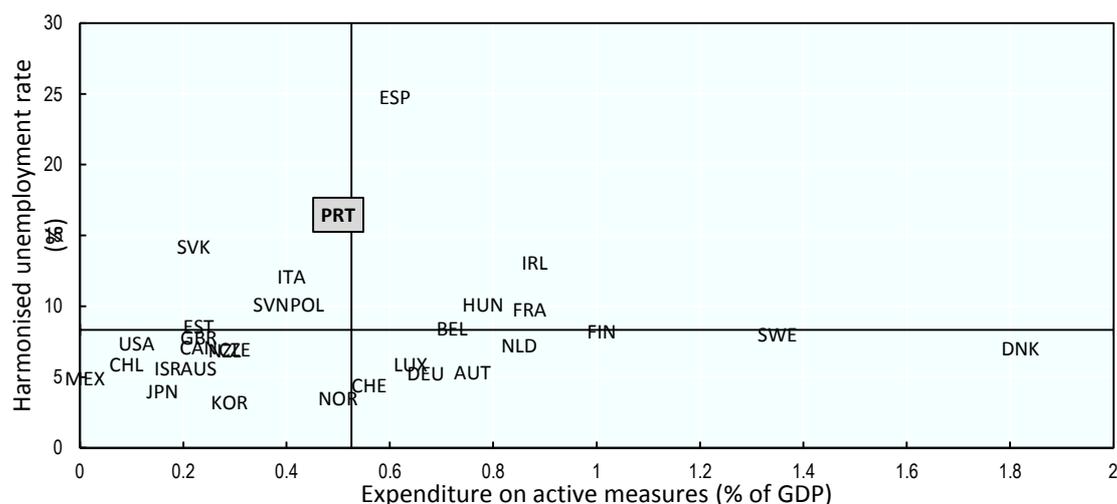

Source: OECD Social Benefits Recipients Database.

As has already been mentioned, there is also scope for further shortening the maximum duration of unemployment benefits in Portugal, which would help reduce the high rate of long-term unemployment (and would also free some resources which could be ploughed back into funding higher coverage rates). This is an issue for older workers in particular, who face the highest incidence of long-term unemployment (Portugal et al., 2015). In most OECD countries maximum benefit duration is age-related (either directly or through the link with previous work experience) and this may be justified on the basis that older workers tend to face worse re-employment prospects when they become unemployed. However, there is a risk that unemployment benefits are used as a pathway to early retirement and the incentive to exit unemployment is likely to fall as retirement nears (Tatsiramos and van Ours, 2012). Going forward, Portugal should consider further reducing the maximum duration of unemployment benefits, particularly for older workers. This should include restricting the possibility of extending unemployment assistance until the age of retirement to only those older people who remain unemployed despite taking active steps to find work. Further reforms of unemployment benefit duration should be combined with efforts to reinforce employment programmes to support the reintegration of job seekers into employment (see below).

***Reforms of the Public Employment Service should be completed, and activation measures targeted on those who need most help***

As the discussion in Chapter 1 showed, Portugal implemented various measures to strengthen its activation strategy over the past few years. Going forward, it is important to build on these successes to further improve the way the unemployed are helped, supported and encouraged to move into rewarding and productive jobs. In particular, Portugal needs to ensure that the measures outlined in the *Programa de Relançamento do Serviço Público de Emprego* are fully implemented. There may also be a need to dedicate more resources to activation. While this may be difficult in the current fiscal climate, it should be remembered that such spending can bring important savings in terms of reduced expenditure on benefits, as well as increased tax revenues. While Portugal's current spending on active measures (as a proportion of GDP) is very close to the OECD average, there are many countries with much lower unemployment rates that spend considerably more (Figure 37). There are also some efficiency gains to be made, for example by better targeting the measures on those who need them most, or by taking a bolder approach to the digitalisation of PES services (European Commission, 2015).

Figure 37. Unemployment and expenditure on ALMPs, 2013

Note: 2010 instead of 2013 for the United Kingdom. 2011 instead of 2013 for Israel. 2012 instead of 2013 for France, Korea, New Zealand, Poland and Spain.

Source: OECD Short-Term Labour Market Statistics Database and OECD Labour Market Programmes Database.

Another interesting recommendation to come out of the Portuguese evaluation literature on active labour market programmes is that the authorities should aim to achieve more stability in the measures available to jobseekers. Writing back in 2012, Costa Dias and Varejão already noted that, between 2000 and 2011, the Public Employment Service offered 167 different programmes, which were often small variations of one another or of previous programmes. As the tables produced in Annex A of this report testify, this continuous change in ALMPs on offer continued over the crisis period, which makes it difficult for jobseekers and firms to know what help is available and also costly for the PES to have to adapt each time to a new set of tools. At the same time, there is a need for more monitoring and evaluation of the existing measures.

Finally, Portugal could try and build stronger incentives into ALMPs to reduce labour market duality. For example, some OECD countries train the unemployed to fill existing vacancies and, in return, expect the employer to hire the individual on a permanent contract (e.g. Individual Job Training in Flanders, Belgium and Work and Income Support in New Zealand). A similar approach could be tried in Portugal – although there is a possibility that such conditions reduce take-up by employers if the risks and costs of taking on an unemployed person on a permanent contract are perceived as being too great. In addition, some of Portugal's existing ALMPs already offer greater subsidies to employers if they hire on permanent contracts (e.g. *Medida Estímulo Emprego* and its predecessors *Estímulo* and *Apoio à Contratação via Reembolso da TSU*). It is important that the effectiveness of such measures be evaluated first, before new measures are introduced.

***The collective bargaining system should promote a closer alignment between wages and productivity at the firm level***

The Portuguese experience has shown that putting restraint on the use of administrative extensions of collective agreements during times of crisis may help achieve wage moderation, preserve jobs and restore competitiveness. There is, of course, a role for extensions of collective agreements, particularly during times of healthy economic growth: they reduce wage inequality as well as gender pay gaps (Villanueva, 2015) – and this is one of the reasons many OECD countries have legal provisions in place for them. However, most of these countries also impose rules on the representativeness of collective agreements before they can be extended and, in Portugal, this is an issue that should continue to be monitored closely. While the first condition requiring signatory employers to represent 50% of workers in the sector/occupation/geographical area was too stringent, the second condition which allows extension when 30% of signatory firms are small and medium enterprises is too lax, given that 99.7% of firms in Portugal are SMEs. It would make sense, therefore, to continue revising these criteria so that they are challenging (and therefore encourage employer organisation), as well as realistic.

The key issue with quasi-automatic extensions of collective agreements is that they risk imposing conditions on non-signatory firms which do not reflect their own economic and financial circumstances. This can be particularly damaging in cases (like in Portugal) where: i) the employer organisations and trade unions that negotiate the agreement are not representative of the sector/occupation/region to which the agreement is to be extended; and ii) where the law prohibits nominal wage cuts. Indeed, there is evidence that, in Portugal, the indiscriminate use of extensions has harmed both competitiveness and employment. One possibility going forward would be for the government to extend collective agreements only if they meet certain “public interest” criteria. What exactly these criteria are can vary, depending on economic circumstances. The important thing is that they are announced well in advance by the government, so that the negotiating parties can take them into account during the bargaining process – knowing that, if these criteria are not met, no extension of the agreement will be possible. In the late 1990s in the Netherlands, for example, the minister (successfully) put pressure on the social partners to set the lowest pay scales close to the national minimum wage. By making clear that this measure was intended to save the credibility of extensions, the minister managed to convince the central organisations to influence their affiliates and negotiators to adjust the lowest pay scales.

Another option for limiting the potential negative effects of extensions would be to make them conditional on the inclusion of an opening clause in the original agreement. Such clauses, negotiated by the social partners, would allow companies to deviate from certain sectoral minima or standards under conditions specified in the higher-level agreement. Such firm-level bargaining under the umbrella of a sectoral agreement is common in Scandinavia, as well as in large firms in Germany and France (Visser, 2016). In the case of Germany, some research found that where collective agreements contained opening clauses, firms had lower job reallocation rates, lower job destruction rates and higher job growth rates (Brändle and Heinbach, 2013) – the reason being that opening clauses give firms more flexibility to save jobs through increased flexibility.

It is important, however, that opening clauses, when activated, are done so upon agreement between employers and their worker representatives. An increased use of derogation should therefore go hand-in-hand with measures to improve worker representation at the firm-level, which would strengthen the control function and reduce the risk of abuse by employers. While in most countries unions have tended to oppose the use of opening clauses for fear that it would entail an erosion of their influence, the increased use of such clauses could actually mean that unions have to strengthen their direct engagement with the needs and requirements of employers (Keune, 2010). Opening clauses also increase the likelihood of organised (as opposed to disorganised) decentralisation and, in the context of increased globalisation and declining union membership, they could be seen as a way to stabilise the bargaining system. In Germany, for example, this was the view of the Mining, Chemicals and Energy Industrial Union (Keune, 2010). That being said, opening clauses may also increase conflict between management and workers, and clear and swift procedures should be put in place to resolve potential disagreement. One way of doing this will be suggested below when the temporary withdrawal from collective agreements for “inability-to-pay” or “hardship” will be discussed. Another is to make sure that the conditions under which firms may opt out are clear and objective.

Whether Portugal opts for the use of public interest criteria or the increased use of opening clauses, it may also want to consider introducing an independent body or committee responsible for deciding (or advising the government on) whether an extension should be granted. Such bodies exist in both Finland and Germany, and play a similar role to minimum wage committees in that they distance the decision to increase wages from the political arena. In Germany, this committee consists of three trade union and three employer representatives (from sectors other than the one covered by the agreement), and extensions are granted only if a majority of at least four votes is achieved (Eurofound, 2011). As in minimum wage committees, this body could also include experts.

While increased worker representation would increase the control function in case opening clauses were introduced, it would also help resolve another bottleneck in the Portuguese collective bargaining system, which relates to the possibility of firm-level bargaining. While the most recent reforms in Portugal have attempted to extend the possibility of firm-level bargaining to a greater number of firms, this is unlikely to make much difference in practice because of the poor worker representation in Portuguese firms. Improving worker representation can be achieved by making works councils compulsory in companies of a certain size (as they have done in France with the *Comités d'Entreprise*). Another option is to provide financial incentives. In Italy, while not promoting worker representation *per se*, social security and tax breaks have been introduced for wages negotiated at the firm-level.

In addition to general opening clauses, more flexibility at the firm-level can be achieved through “inability-to-pay” (or “hardship”) clauses which allow employers to temporarily suspend a collective agreement at times of crisis. These are different from the general opening clauses discussed above, which are primarily instruments of organised decentralisation within sectoral agreements and have no place in firm-level agreements (Visser, 2016). By contrast, temporary hardship clauses can apply to any collective agreement at any level and act as a safety valve for employers (Visser, 2016). Late in 2014, Portugal

introduced the possibility of temporary hardship clauses. As with the more general opening clauses, however, an issue arises of how disagreement between employers and worker representatives is resolved – which, if left unaddressed, risks reducing the practical applicability of such clauses. To minimise such disagreements, either the law or collective agreements should include objective conditions under which employers may temporarily suspend a collective agreement. In Spain, for example, sectoral agreements have to include objective conditions (such as a fall in sales or productivity over a specified period of time) that specify when firms may opt out of what was agreed. In addition, a swift arbitration process in the case of disagreement between employers and worker representatives. Again, the example of Spain could be followed, where employers wanting to opt out can now, in the absence of an agreement with workers' representatives, unilaterally refer the matter to arbitration by a public tripartite body. Importantly, once the issue has been settled by arbitration, it may no longer be challenged (except on some very limited grounds; OECD, 2012). Such arbitration could also be used in the case of disagreement about the activation of standard opening clauses discussed above.<sup>81</sup>

Finally, it will be important in Portugal to improve trust between the social partners. Evidence from the Global Competitiveness Report, which gathers the opinions of business leaders around the world, suggests that trust in social partners in Portugal is consistently lower than across the OECD on average. The crisis years, and the reforms and austerity measures that were implemented during those years, have put significant strain on the relationships between the social partners. Távora and González (2014) provide a comprehensive overview of the strikes and demonstrations that took place during this period which include several general strikes, of which three were organised by the two union confederations “in an (almost) unprecedented display of unity of the Portuguese labour movement” (Távora and González, 2014). The main union confederation (CGTP) refused to sign any agreement with the government. In some cases (e.g. the fixing of the statutory minimum wage in 2011), the social partners were not even consulted by the government. At the same time, the issue of trust is gaining growing attention as an important determinant of the outcome of the collective bargaining process (Addison, 2015), and some researchers, like Blanchard, Jaumotte and Loungani (2013), have argued that “trust among the social partners appears to be just as important in bringing about macro flexibility as the structure of collective bargaining.” This was already recognised by Freeman and Medoff (1984), according to whom good labour relations are more likely to result in positive performance outcomes. While building trust between social partners is a complex process, implementing some of the reforms put forward by this report would help, including: making unions and employer organisations more inclusive; introducing objective criteria for both extensions and opt-outs; and encouraging regular negotiations (e.g. by reducing the maximum length of time for which agreements can remain valid) (Hijzen, Martins and Parlevliet, 2016).

### ***Minimise the possible negative employment effects of future increases in the minimum wage***

Chapter 1 argued that the freezing of the minimum wage between 2010 and 2014 hurt workers and that, in 2013, minimum-wage workers needed to work a relatively high number of hours to be able to move above the relative poverty line. At the same time, the Portuguese minimum wage is high relative to median wages and is also very binding: in October 2014, it was estimated that one in five full-time workers was earning the minimum wage, which was up from 13% in April that same year (GEP, 2015). Of particular concern in Portugal is that employer social security contributions on minimum-wage workers tend to be higher than in other countries, which would exacerbate any negative effect of the minimum wage on hiring. Given that Portugal continues to struggle with competitiveness (Chapter 2), the raising of the minimum wage to EUR 530 in 2016 and to EUR 600 by 2019 should raise some alarm bells. While some reductions in employer social security contributions for existing minimum wage workers will continue to

81. One concern, as pointed out by Ramalho (2013) is that in Portugal “There [...] appears to be no tradition of resolving differences of opinion between parties in regard to collective agreements and collective bargaining by means of mediation and arbitration.”

be available, the next section of this chapter will argue that, in order to stimulate labour demand, this measure should be extended to all minimum wage workers (not just existing ones). This may be particularly important in the case of small firms since these are likely to bear the brunt of any minimum wage increase (GEP, 2015).<sup>82</sup>

An alternative (or, rather, complementary) way of supporting the incomes of low-wage workers is through in-work benefits. Indeed, a recent review of minimum wage policy in OECD countries concluded that a careful combination of minimum wages and in-work benefits can be more effective in tackling in-work poverty than either instrument on its own (OECD, 2014b). The advantage of in-work benefits is that they have no negative effect on labour demand. Their introduction would however put additional pressure on the public purse, which may not be feasible given the current fiscal climate in Portugal. An additional concern often raised with in-work benefits is that they would simply be off-set by lower wage increases, but this risk is mitigated for the lowest earners by the presence of the minimum wage. Indeed, one of the stated aims of introducing the UK National Minimum Wage, for example, was to ensure that in-work benefits would actually increase the incomes of workers (rather than being “pocketed” by employers who might reduce wages by a similar amount). In addition, there is no need for employers to know which employees applied for and received the in-work benefit (as is the case in the United States with the Earned Income Tax Credit). Finally, while Portugal may not currently have an in-work benefit or tax credit along these lines, it should be remembered that the tax system in Portugal is very progressive which, to all intents and purposes, is a functional equivalent (except, perhaps, that it is less targeted than in-work benefits can be).

Looking forward, Portugal should consider setting up an independent body responsible for providing the government with impartial advice on future changes to the minimum wage, based on up-to-date and accurate information on current labour market conditions and the views of social partners. Such bodies, which bring together labour market experts, employer and employee representatives, now exist in different forms in several OECD countries, including: Australia, France, the United Kingdom and several US states. They have the advantage of making the minimum-wage uprating mechanism more fair, open and transparent.

### **Other challenges**

#### ***Returning to higher and more sustainable rates of growth***

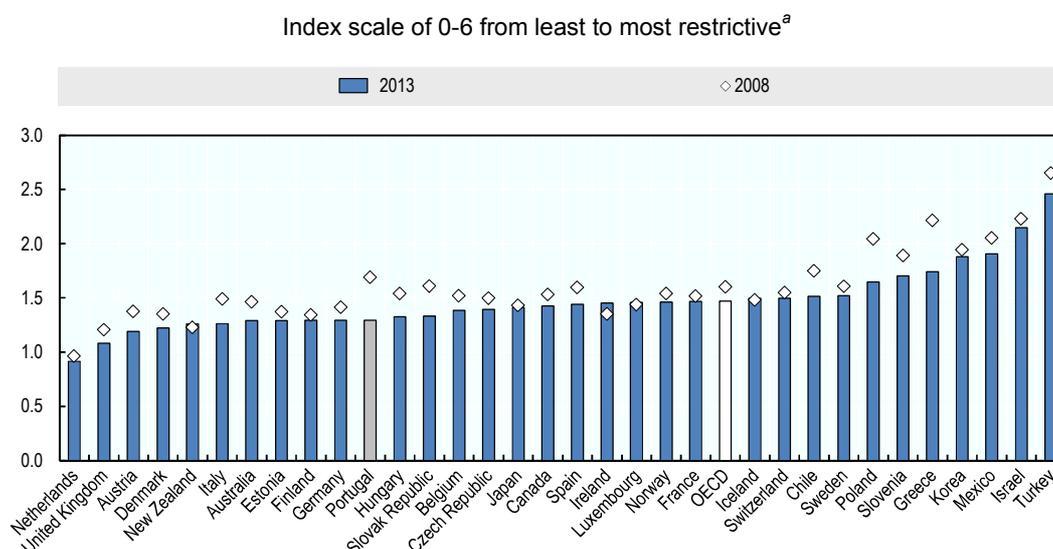

A return to higher and more sustainable growth remains a critical condition for further improvements in the labour market. Projections by international organisations, including the OECD, expect a continuation of the economic recovery in Portugal with growth rates in the range of 1.25% in 2017 and 2018. This implies that growth will remain substantially below the average growth rates projected across the OECD. Based on these projections, the pace of the recovery in Portugal would probably allow further reductions of the unemployment rate, albeit only small ones.

#### ***Pushing through further product market reforms***

Economic growth can be held back by product market regulations that put frictions on the entry and expansion of firms. Since 2008, Portugal has implemented a wide range of measures to strengthen the competition-friendliness of its product market regulation and has moved up 15 ranks among OECD countries. For the aggregate indicator, Portugal is currently ranked 11th of 33 OECD economies for which data is available (Figure 38).

---

82. There is also a concern that a high national minimum wage floor may undermine future collective agreements, since employers will be less willing to negotiate increases in wages when the national minimum wage is already so high.

Figure 38. **Aggregate product market regulation indicator, 2008-2013**

a. The OECD aggregate is an unweighted average of the data shown.

Source: OECD (2013), OECD Product Market Regulation Database.

However, while markets for tradable goods are generally competitive in Portugal (as is to be expected in a small open economy), some non-tradable sectors such as energy, transport and professional services continue to be characterised by low levels of competition. Given that intermediate inputs from non-tradable sectors are one of the most important cost inputs for firms in the tradable sector, the scope for further competitiveness gains and enhanced export performance depend crucially on the economy's ability to restrain input prices.

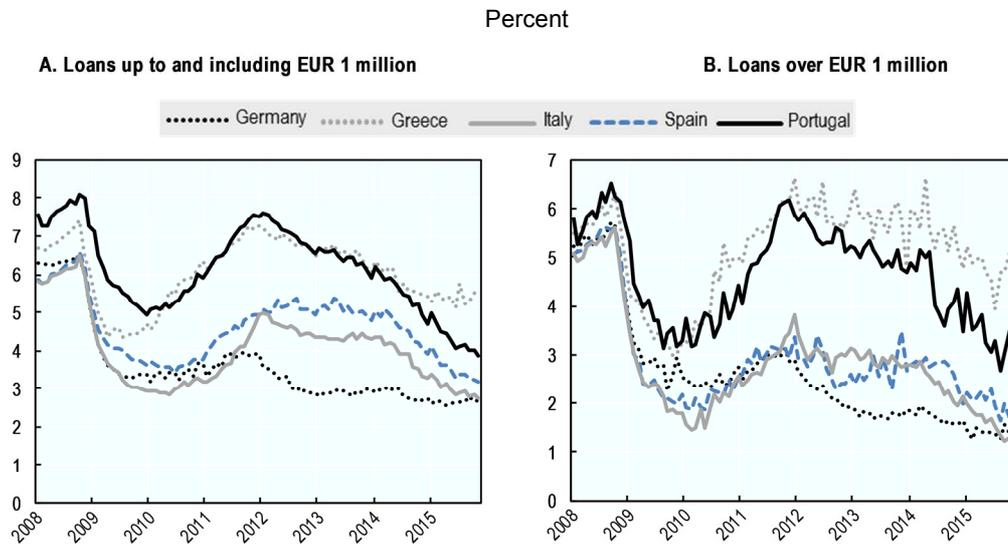

Recent OECD simulations (OECD, 2014c) suggest that further reductions in regulatory barriers to competition could significantly boost growth rates in Portugal. For example, in a scenario where Portugal reduces such barriers by 20% (corresponding roughly to the magnitude of changes observed over the past ten years in those OECD countries that have implemented product market reforms), GDP would increase by an additional 2% by 2020. In a more ambitious scenario in which Portugal aligns its regulation to best practice among all OECD countries in the various areas and sectors of product market regulations would yield an increase in the level of productivity and GDP of 5.5% by 2020, and even more over the longer term.

Going forward, it is therefore essential that Portugal continues to look for ways to improve its product market regulation which, in turn, will allow firms in other sectors to benefit from better inputs at lower prices, as well as better quality products and services. While a new framework law was approved in 2013 that reforms regulations in 18 professional services, none of the new statutes and internal rules for the professional bodies have been approved yet (nine have reportedly been finalised but not yet approved, while nine others are experiencing delays – European Commission, 2015). Similarly, some measures aimed at reducing the cost of energy and the use of transport infrastructure still need to be implemented.

### ***Improving access to credit for firms***

Job creation in Portugal has been held back also by financial constraints weighing on firms. Although the cost of credit in Portugal has been falling substantially, it remains high compared to some other OECD countries, including Italy and Spain (Figure 39) and, for large loans, recent data indicate that interest rates might be rising again. Against this backdrop, lending to the private sector still continues to fall, although at a decreasing rate (Figure 40). One of the issues that may have to be addressed to enhance access to finance for firms with strong growth potential is the high level of corporate indebtedness and the poor performance of some assets on banks' balance sheets, which is restraining their lending capacity.

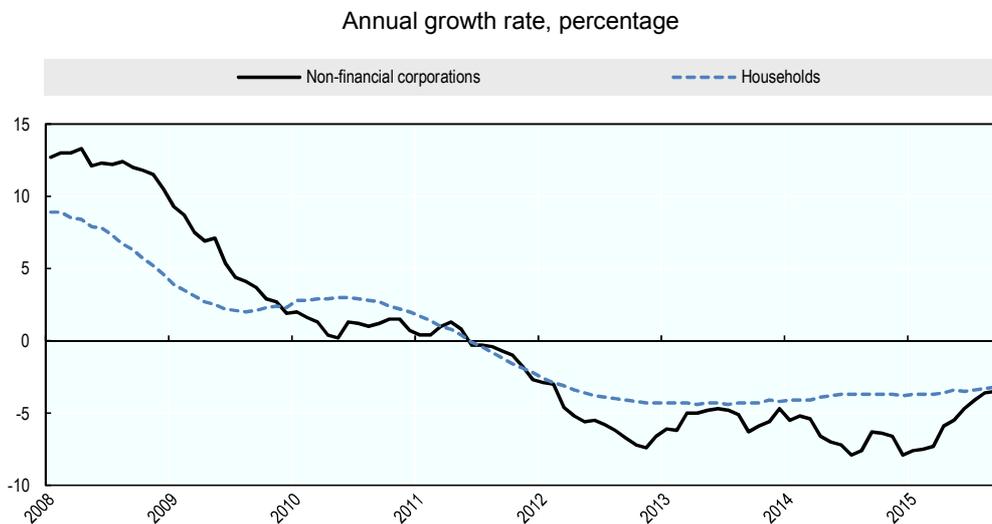

Figure 39. Interest rates on loans to non-financial corporations, January 2008–November 2015, Portugal and other EU countries

Note: Balance sheet item: loans other than revolving loans and overdrafts, convenience and extended credit card debt. Original maturity/Period of notice/Initial rate fixation: up to one year. MFI interest rate data type: annualised agreed rate (AAR) / Narrowly defined effective rate (NDER).

### Reducing the tax wedge

Portuguese companies are taxed more than in the average OECD country (OECD, 2014c), and this has negative consequences for their competitiveness. Some commentators even go as far as saying that this tax burden is one of the key barriers to better labour market performance in Portugal (Palma Ramalho,

2013; Carvalho Martins, 2014).<sup>83</sup> Of particular relevance for the present report is the tax wedge on labour income, which measures the sum of personal income tax, employee and employer social security contributions (net of family benefits) as a proportion of total labour costs (i.e. gross wages plus employer social security contributions). It is a measure of the difference between how much employers pay to hire a worker, and how much that worker takes home in net pay. The tax wedge therefore has an impact on both labour demand (by affecting the cost of hiring) as well as on labour supply (through its relationship with the reservation wage). As an illustrative example, Figure 41 shows the average tax wedge in OECD countries on a single worker with no children. At 41.2% versus 36.0%, the tax wedge in Portugal is considerably higher than the OECD average, and this difference is due entirely to higher social security contributions paid by Portuguese employers.<sup>84</sup>

Figure 41. Average tax wedge, 2014

Source: OECD (2015), *Taxing Wages 2015*, OECD Publishing, Paris.

Plans to reduce employer social security contributions and compensate for the lost revenue through increases in VAT were, unfortunately, shelved (Portugal, 2015) – but such reductions would still be useful in boosting labour demand. While an across-the-board cut in employer social security contributions may be unrealistic in the current financial climate, more targeted reductions for disadvantaged workers might be more feasible. For example, a number of OECD countries (France most notably, but also Hungary, the Netherlands, Belgium and the United Kingdom) have lower employer social security contributions on minimum-wage earners than on median-wage earners (OECD, 2015c). Similarly, when Portugal increased the minimum wage to EUR 505 in October 2014, it introduced a cut in employers' social security contributions (of 0.75 percentage points) – though only for minimum-wage workers who were already hired prior to June 2014. While this measure was welcome, a wider application of it to all minimum-wage

83. The adverse effect of the tax wedge on employment may be larger in countries where extensions are common (Murtin, de Serres and Hijzen, 2014).

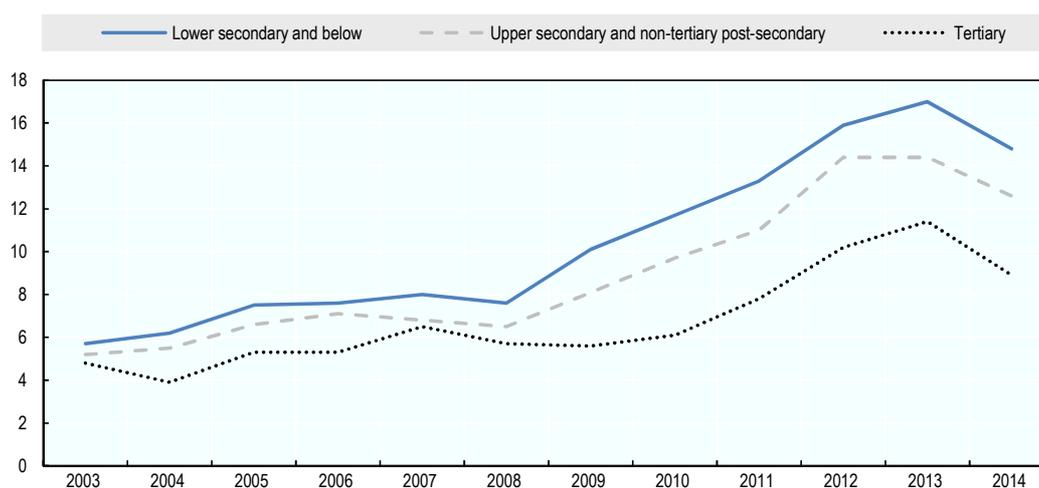

84. In 2013, the government introduced an exceptional income tax surcharge of 3.5% (*sobretaxa extraordinária em sede de Imposto sobre o Rendimento das Pessoas Singulares – IRS*). The new XXI Constitutional Government established on 26 November 2015 has approved a reduction in this surcharge from 3.5% to 1.75% in 2016 and to 0% in 2017. Finally, the new government has plans to introduce a negative income tax (*Complemento Salarial Annual*) for the poorest workers.

workers would have been even more helpful so as to encourage new hiring. With large increases planned in the minimum wage (to EUR 600 by 2019), such cuts in employer social security contributions gain even more relevance. The fiscal cost of such a measure would be mitigated by the reductions in benefit expenditure resulting from higher levels of employment.<sup>85</sup>

### *Investing in skills*

One key challenge that Portugal continues to face in achieving higher levels of productivity (but also inclusiveness) lies in the poor (and unequally distributed) skills of its workforce. Individuals with higher skills have better labour market outcomes. In Portugal, for example, the unemployment rate of 25-64 year-olds with less than tertiary education more than doubled between the start and the peak of the crisis. While those with tertiary education also saw a significant increase in their unemployment rate, the increase was significantly less marked than for those with lower levels of education (Figure 42). In 2014, an individual with less than upper-secondary education was 1.7 times more likely to be unemployed than an individual with tertiary education. There are also important returns to higher education in Portugal, reflecting the fact that demand outstrips supply. The internal rate of return to a tertiary education is 18.7% for men and 20.5% for women (compared to 14.0% and 11.5% across the OECD on average; OECD, 2015d).

Figure 42. **Unemployment rates of the population aged 25-64 by educational attainment, 2003-2014, Portugal**

Note: Because of a methodological change in the Portuguese Labour Force Survey, data prior to 2011 are not fully comparable with the more recent data. The new methodology results in higher levels of unemployment and inactivity compared to the methodology used prior to 2011. For detailed information, see Statistics Portugal (2011).

Source: Eurostat.

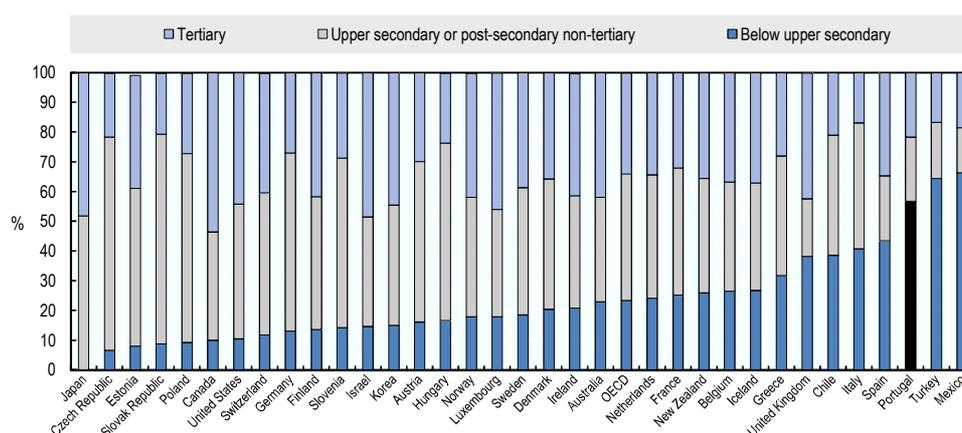

In recent years, Portugal has made significant improvements in the educational attainment of its adult population (OECD, 2015d). Despite this, Portugal lags behind all other OECD countries (except Turkey and Mexico) in terms of the proportion of 25-64 year-olds who have attained at least upper secondary education (Figure 43). Such low levels of attainment can be explained by the low level of attainment among older adults (55-64 year-olds), where eight out of ten have not attained upper secondary education.

85. The XXI Constitutional Government has proposed a reduction in VAT on restaurants as part of the 2016 budget. While such measure might promote employment, it is much less targeted: i) on employment and ii) on low-paid workers than reductions in social security contributions would be. There are many low-paid workers in other sectors, and similarly there are many high-paid workers in the restaurant sector.

Similarly, although Portugal was one of the OECD countries that made the greatest progress between 2003 and 2012 on the PISA tests of mathematics performance of 15-year-olds, its average score remains below the OECD average (Figure 44). Against this background, it is worth mentioning the fact that Portugal has engaged with the OECD in a comprehensive diagnosis of its key skills challenges (OECD, 2015e). The outcome of the exercise provides a solid basis for identifying possible actions to enhance skills development, skills activation and skills use. It provides examples illustrating how other countries have tackled similar challenges, which can be used as input for framing potential policy options for Portugal.

## ANNEX A

**DETAILED OVERVIEW OF LABOUR MARKET REFORMS IN PORTUGAL  
OVER THE PERIOD 2011-2015**

**Employment Protection Legislation***Severance pay reforms**Open-ended contracts*

Prior to the reforms, the severance pay of workers on open-ended contracts was calculated as one month (30 days) of base wage and tenure-based increments for every full year of tenure – with a minimum of three months.<sup>86</sup>

Over the period 2011-2013, several amendments were made to the severance pay system for open-ended contracts:

- From 1 November 2011 onwards,<sup>87</sup> severance pay on all new open-ended contracts was reduced from 30 to 20 days for each year of tenure, and the minimum requirement of three months was removed. In addition, limits were introduced to the maximum amount of severance pay that could be paid out. Specifically: the base wage (including tenure-based increments) for calculating the entitlement was capped at 20 times the national monthly minimum wage; and the total amount of severance pay could not exceed 12 times the worker's base wage (including tenure-based increments) – i.e. 240 times the national monthly minimum wage.
- From 31 October 2012,<sup>88</sup> some of these new rules were also applied to contracts signed prior to 1 November 2011 – although rights accrued so far were preserved. So, for these contracts, the rules now stipulated that compensation accrued at 30 days per year of tenure up until 31 October 2012, and then at 20 days per year of tenure for years after that. The minimum of three months' pay was maintained, and the new upper limits would also be applied. One exception would be for those individuals whose accumulated compensation rights on 31 October already exceeded the upper limits. In those cases, individuals would simply keep the rights already accrued (even if above the limit), but with no further accruals beyond that date.

---

86. The formula for calculating the amount of severance pay was originally defined by Decree-Law 372-A/75 of 16 July and workers were entitled to one full month of severance pay for every year (or fraction of a year) of tenure. Decree-Law 64-A/89 of 12 February specified that the basis on which the amount of severance pay was to be calculated was the base wage (excluding overtime pay or bonuses). However, the Labour Code of 2003 subsequently added tenure-based increments to the calculation. The LC 2003 also specified that, in the case of fractions of years of tenure, the amount of severance payment was to be calculated proportionally.

87. Law 53/2011 of 14 October.

88. Law 23/2012 of 25 June.

- From 1 October 2013,<sup>89</sup> a further reduction in severance pay was introduced: from 20 to 12 days per year of tenure, with a temporary regime for contracts for which the duration on 1 October 2013 was inferior to three years. Because rights accrued to date were preserved, three regimes now applied depending on when the employment contract was signed:
  - For contracts signed before 1 November 2011:
    - 30 days per year of tenure until 31 October 2012;
    - 20 days per year of tenure between 1 November 2012 and 30 September 2013;
    - For the period after 1 October 2013:
      - ❖ If the overall contract duration was inferior to three years on 1 October 2013: 18 days per year of tenure for the first three years of the contract and 12 days per year of tenure for every year after that.
      - ❖ If the overall contract duration was three years or more on 1 October 2013: 12 days per year of tenure.
  - For contracts signed between 1 November 2011 and 30 September 2013:
    - 20 days per year of tenure for the period up to 30 September 2013;
    - For the period after 1 October 2013:
      - ❖ If the overall contract duration was inferior to three years on 1 October 2013: 18 days per year of tenure for the first three years of the contract and 12 days per year of tenure for every year after that.
      - ❖ If the overall contract duration was three years or more on 1 October 2013: 12 days per year of tenure.
  - For contracts signed after 1 October 2013:
    - 12 days per year of tenure.

#### *Fixed-term contracts*

Prior to the reforms, temporary workers whose contracts were not renewed or converted to permanent ones by their employers were entitled to severance pay equal to: three days of base pay and tenure-based increments per month of work in case of contracts that lasted six months or less; and two days of base pay and tenure-based increments per month of work in case of contracts that lasted more than six months.

From 1 November 2011 onwards,<sup>90</sup> severance pay on all new fixed-term contracts was aligned with that of all new open-ended contracts – i.e. 20 days for each year of tenure, with fractions of a year counted proportionally and upper limits applying.

From 31 October 2012 onwards, the new rules were also extended to contracts signed prior to 1 November 2011 – although rights accrued to date were preserved. Severance pay was therefore equal to two or three days per month of tenure for the period up until the 31<sup>st</sup> of October 2012, and 20 days per year of tenure for years after that (with the new upper limits applicable).

89. Law 69/2013 of 30 August.

90. Law 53/2011 of 14 October.

Finally, from 1 October 2013, severance pay was further reduced to 18 days per year of tenure, up to the ceilings defined above. As in the case of open-ended contracts, rights accrued to date were preserved, so that three separate regimes are now applicable, depending upon when the original contract was signed (and taking account of the two exceptional extensions of temporary contracts which were allowed):

- For contracts signed before 1 November 2011:
  - For the period up to and including 31 October 2012: three days of base pay and tenure-based increments per month of work in case of contracts that lasted six months or less; and two days of base pay and tenure-based increments per month of work in case of contracts that lasted more than six months.
  - For the period between 1 November 2012 and 30 September 2013: 20 days per year of tenure (with fractions of a year counted proportionately).
  - For the period after 1 October 2013:
    - ❖ If the overall contract duration was inferior to three years on 1 October 2013: 18 days per year of tenure for the first three years of the contract and 12 days per year of tenure for every year after that.
    - ❖ If the overall contract duration was three years or more on 1 October 2013: 12 days per year of tenure.
- For contracts signed between 1 November 2011 and 30 September 2013:
  - For the period up to and including 30 September 2013: 20 days per year of tenure (with fractions of a year counted proportionately).
  - For the period after 1 October 2013:
    - ❖ If the overall contract duration was inferior to three years on 1 October 2013: 18 days per year of tenure for the first three years of the contract and 12 days per year of tenure for every year after that.
    - ❖ If the overall contract duration was three years or more on 1 October 2013: 12 days per year of tenure.
- For contracts signed between 1 October 2013:
  - 18 days per year of tenure (with fractions of a year counted proportionately).

Table A1 below summarises all the changes to severance pay (for both open-ended and temporary contracts).

Note that, in addition to the reforms outlined above, the 2012 amendment of the Labour Code declared void all provisions contained in collective agreements signed prior to the entry into force of the new Labour Code which established higher amounts of severance pay than those resulting from the Labour Code.

Table A1. Changes over time in severance payment for open-ended and fixed-term contracts

> 01/10/2013				18 days per year of tenure for the first three years of the contract and 12 days per year of tenure for every year after that upper limits applicable

### ***Introduction of a dismissal fund***

Two dismissal funds were set up in October 2013<sup>91</sup> which collect compulsory monthly contributions from employers into individual savings accounts of workers, and which are intended to cover part of the severance payment in case of dismissal.

To be precise, the new law introduced a severance pay fund (*Fundo de Compensação do Trabalho – FCT*), the “equivalent mechanism” (ME) and the severance pay guarantee fund (*Fundo de Garantia de Compensação do Trabalho – FGCT*). Monthly contributions to these funds are compulsory for each worker hired on or after 1 October 2013 and are set at 0.925% of the worker’s wage for the FCT and 0.075% in case of the FGCT. In practice, these contributions are waived for the first two years of the existence of the fund (or until the employment contract is terminated, whichever comes first) through the temporary Employment Incentive measure (*Incentivo Emprego*).<sup>92</sup> Since September 2015, contributions to the fund stop once the accumulated amount has reached 50% of the severance pay due to the employee in case of dismissal.<sup>93</sup>

The FCT acts as a savings account for the employer and is intended to cover up to half of the severance payment. In this way, it reduces the up-front cost of high severance payments. The fund is managed by the Institute for Social Security Funds Management (*Instituto de Gestão de Fundos de Capitalização da Segurança Social*), but employers may also opt to go with a private fund instead (through the equivalent mechanism) if they think they can obtain better returns that way. When an employee is dismissed, the employer applies to the fund to pay the part of the severance pay that has been saved up, with the employer paying the remaining part.

The FGCT is intended as an insurance fund to which the employee can apply in case the employer’s payment plus the accumulated amount in the FCT fail to add up to 50% of the severance pay entitlement. The FCGT essentially makes sure that, in case of dismissal, the employee receives at least 50% of his/her severance pay entitlement.

If the employee leaves the employer of his/her own accord, the employer can obtain a refund of that worker’s dismissal fund.

### ***Changes to the definitions of fair dismissal***

Changes were introduced to the definitions of fair dismissal linked to: i) the extinction of a work position; and ii) inadaptability. The new regulations have been in force since 1 August 2012.<sup>94</sup>

#### *Dismissal for extinction of a work position*

Prior to the reforms, the law laid down a number of conditions that needed to be fulfilled in case an employer wanted to dismiss a worker for extinction of a work position. The first of these required the employer to prove that s/he could not offer the worker another position, compatible with his/her professional profile. Second, in the event that several comparable positions existed within the workplace, the employer needed to follow strict, seniority-based rules to select the worker to be dismissed (“last in,

91. Law 70/2013 of 30 August.

92. Ordinance 286-A/2013 of 16 September. Ordinance 17/2014 of 27 January brings some improvements in the administrative process of the *Incentivo Emprego*.

93. Decree-Law 210/2015 of 25 September.

94. Law 23/2012 of 25 June.

first out”), namely the worker with: i) the least seniority in the position; ii) the least seniority in the professional category; iii) the lowest level within the professional category; iv) the least seniority within the firm.<sup>95</sup>

Regarding the criteria for deciding which worker to dismiss, these were removed as of 1 August 2012 and replaced by “relevant and non-discriminatory” criteria to be defined by the employer him/herself and which should be directly related to the reason for extinction of the work position. However, in September 2013, this change was judged to be unconstitutional by Portugal’s Constitutional Court<sup>96</sup> and, in response to this, another revision of the criteria took force on 1 June 2014.<sup>97</sup> The new dismissal criteria require employers to select the worker: i) with the worst performance evaluation (measured against benchmarks previously known to the employee); ii) with the lowest academic and professional qualifications; iii) who presents the greatest cost burden to the employer; iv) with the least experience in the position; v) with the least seniority within the firm.

The second change introduced as of 1 August 2012 was the elimination of the requirement that the employer should try and find another suitable position for the worker s/he intends to dismiss (sometimes referred to as *repêchage*). While the removal of this condition was unlikely to make much difference in practice,<sup>98</sup> the Constitutional Court also ruled this change unconstitutional,<sup>99</sup> and it was subsequently reinstated (as of 1 June 2014).<sup>100</sup>

#### *Dismissal for inadaptability*

According to the Labour Code of 2009 a worker could be dismissed for inadaptability in situations where s/he: i) displayed a continuous fall in productivity or quality; ii) caused repeated damage to equipment or machinery; iii) presented a risk to the health and safety of him/herself, other employees, or third parties.

In order to dismiss a worker for inadaptability, a number of conditions needed to be met by the employer: i) six months prior to the start of the dismissal procedure, changes needed to have been introduced to the nature of the job as a result of technological change or the adoption of new production/sales practices; ii) the worker needed to have been offered appropriate training in a certified institution to allow him/her to adapt to the changes in the post; iii) after the training, the worker needed to have been granted a period of adaptation on the job of at least 30 days; iv) there was no other suitable position within the organisation that could be offered to the worker; and v) the situation of inadaptability did not derive from a lack of health and safety conditions for which the employer was at fault. If these

95. One exception to this rule applied to firms with fewer than 50 registered employees in the previous calendar year, in which case the employer could resort to the rules governing collective dismissal (which do not contain seniority-based requirements for choosing the worker to be dismissed) if at least two workers were to be dismissed (Pestana Nascimento, 2012).

96. Decision n° 602/2013 of the Constitutional Court on 20 September 2013. The new criteria were judged to be too subjective.

97. Law 27/2014 of 8 May.

98. It would hardly be accepted that an employer eliminated a work position while, at the same time, recruiting workers for an equivalent position/professional category (Pestana Nascimento, 2012).

99. Decision n° 602/2013 of the Constitutional Court on 20 September 2013.

100. Law 27/2014 of 8 May.

conditions were all fulfilled, the employer also needed to comply with certain notification and consultation procedures prior to proceeding with the dismissal.<sup>101</sup>

On 1 August 2012, two changes were introduced to this procedure.<sup>102</sup> First, as in the case of dismissal for extinction of a work position, the *repêchage* condition was removed – although this has subsequently been re-introduced after the Constitutional Court judged this change to be unconstitutional.<sup>103</sup> There is one important exception to this, however. Indeed, the second change introduced on 1 August 2012 implied that, henceforth, dismissal on the grounds of inadaptability could also apply in cases where no changes to the nature of the job had been introduced. In addition, there is no requirement under this modality that the employer offers the worker an alternative and suitable position within the workplace (Monteiro Fernandes, 2014).

### ***Exceptional extension of temporary contracts***

In Portugal, fixed-term contracts can only be used to meet a temporary need of the company and for the period strictly necessary to meet this need. In addition, fixed-term contracts may be used: i) for the launch of a new activity of undefined duration or the start-up of a company (or establishment) with fewer than 750 workers; and ii) in the case of first-time jobseekers, the long-term unemployed, or other situations specified in special employment policy legislation. Fixed-term contracts can be renewed up to three times and their total duration (including all renewals) cannot normally exceed three years (in the case of temporary contracts of pre-defined duration). Some exceptions to this rule are made for: i) first-time jobseekers (18 months overall duration); ii) the long-term unemployed and contracts signed in the context of the launch of a new activity and or a new start-up (24 months overall duration). Temporary contracts of uncertain duration may last up to six years.

During the period of the reforms, two exceptional extensions of temporary contracts (of pre-defined duration) were allowed. The first exceptional extension came into force on 11 January 2012<sup>104</sup> and allowed two additional extensions (not exceeding 18 months overall) of all fixed-term contracts that were set to reach the maximum limit of duration by the end of June 2013. In addition, the duration of each exceptional renewal could not be less than one sixth of the maximum duration of the fixed-term contract or its effective duration, whichever is lower. The validity of contracts renewed under this law expired on 31 December 2014. The second exceptional renewal came into force on 8 November 2013<sup>105</sup> and allowed all fixed-term contracts that would reach the maximum limit of duration by 7 November 2015 to be extended twice (but not exceeding 12 months overall). Once again, the duration of each exceptional renewal could not be less than one sixth of the maximum duration of the fixed-term contract or its effective duration, whichever is lower. The validity of contracts renewed under this law expires on 31 December 2016.

### ***Employment contracts of very short duration***

The Portuguese Labour Code specifies a special form of temporary contract of very short duration (*muito curta duração* – introduced in 2009) which can be used for the purposes of seasonal agricultural

---

101. In addition, inadaptability can arise in situations where workers assigned to technically complex posts or in positions of management did not meet the objectives previously agreed with them in writing. In this case, the employer only needs to fulfil conditions i) and v) in order to proceed with the dismissal.

102. Law 23/2012 of 25 June.

103. Decision n° 602/2013 of the Constitutional Court on 20 September 2013; and Law 27/2014 of 8 May.

104. Law 3/2012 of 10 January.

105. Law 76/2013 of 7 November.

activities or the organisation of touristic events. This contract is not subject to written form, although its celebration should be communicated electronically to social security. Prior to the reforms, these contracts could last no longer than a week, with a limit of 60 days over a period of 12 months. The length of these contracts was increased to 15 days, and the overall annual limit to 70 days.<sup>106</sup>

### ***Measures to tackle dependent self-employment***

The reforms also attempted to tackle labour market segmentation by reducing the level of “dependent self-employment”. The Labour Code of 2009 already defined the conditions under which an employment contract would be presumed (i.e. under which the worker would be considered a wage earner), but the new law<sup>107</sup> provides labour inspectors with the necessary tools to enforce the existing regulations. In particular, a procedure was introduced which should be followed in case a labour inspector detects misuse of service provider contracts. In a first instance, the employer is given ten days to regularise the situation. If this fails, a process is initiated to establish an employment contract. The new law came into force on 1 September 2013.

### **Collective bargaining**

The recent labour market reforms introduced a number of changes to collective bargaining in Portugal.

#### ***New criteria for the extension of collective agreements***

Prior to the reform, the most common form of collective agreement in Portugal was the sectoral agreement (*Contrato Coletivo de Trabalho*, CCT), which is an agreement negotiated between one or more employer organisations and one or more trade unions. The two other forms of collective agreement in Portugal are: i) agreements between groups of firms (*Acordos Coletivos de Trabalho* – ACT), which are signed by several employers that are not part of an employer organisation and one or more trade unions; and ii) firm-level agreements (*Acordos de Empresa*) involving just a single employer. ACTs are common in the financial and utilities sectors, while firm-level agreements (which are less common) occur most often in the oil, transport and communication sectors (Addison, Portugal and Vilares, 2015).

In Portugal, collective agreements are only binding for trade union members. In practice, however, employers who sign an agreement generally extend its application to their entire workforce, irrespective of the union status of their workers.<sup>108</sup> This is partly because there is no legal mechanism in Portugal that obliges trade unions and employer organisations to disclose their membership. In addition, the Ministry of Employment, Solidarity and Social Security has traditionally extended collective (sectoral) agreements to the whole sector (using *portarias de extensão* or extension ordinances), upon request of at least one of the parties to the agreement.

The extension of collective agreements was frozen from May 2011 onwards, and this suspension remained in force until 2012, when changes were introduced to the criteria for awarding extensions.<sup>109</sup> The idea behind the reform was to extend agreements only if they were representative of the sector,

---

106. Law 23/2012 of 25 June.

107. Law 63/2013 of 27 August.

108. Employers extending collective agreements to non-union employees is common practice in most countries, if only to prevent tensions within the workforce. In some countries application to non-union members is required by law (as in the Netherlands).

109. Cabinet Resolution 90/2012 of 31 October 2012.

geographical area or occupation they are meant to cover. So, besides a new requirement that at least one union and one employer organisation now needed to request the extension, the latter will only be granted if the employers that signed it employed at least 50% of the workers in the sector, geographical area or occupation to which the agreement is to be extended. In June 2014, this requirement was softened by addition of a new, alternative requirement which stated that extension agreements will also be considered if the signatories to the agreement consist of at least 30% of micro-, small- and medium-sized enterprises (employing up to 250 employees each).<sup>110</sup>

### ***Firm-level bargaining***

Since 1 August 2012, works councils have been able to negotiate at plant level in firms with at least 150 employees (previously this was limited to firms with at least 500 employees). However, because the Portuguese Constitution gives trade unions exclusive rights to represent workers in the negotiation process (Article 56 of the Constitution), this can only happen if the latter delegate the power to negotiate to workers' associations. The attempt to encourage greater decentralisation of collective bargaining was accompanied by the creation of an Industrial Relations Centre (*Centro de Relações Laborais*), whose purpose it is to provide information and technical assistance to the parties involved in collective bargaining.<sup>111</sup>

From September 2014 onwards,<sup>112</sup> the government also introduced the possibility of collective agreements to be temporarily suspended in cases where the firm finds itself in a situation of crisis, due to market conditions, structural or technological reasons, or other events that have seriously impacted on the normal, day-to-day activity of the firm – as long as this suspension is indispensable for the survival of the firm and to avoid employment losses. Prior agreement needs to be reached with trade unions, and such agreement needs to state very clearly the reason for the suspension and its duration.

Finally, while articulation has, in theory, already been possible since the 2003 Labour Code,<sup>113</sup> this rarely occurred in practice (MTSS, 2006; Távora and González, 2015). The recent reforms further encouraged the inclusion of articulation clauses between different levels of bargaining, particularly on matters of functional and geographical mobility, the organisation of working time, and compensation.<sup>114</sup>

### ***Expiry of collective agreements***

The reforms also targeted cessation clauses contained within certain collective agreements which stipulate that the agreement remains in force until it is replaced by a new agreement (which, in practice, means it could remain in force indefinitely). The Labour Code of 2009 already prohibited such clauses in new agreements, and put a limit on the validity of cessation clauses in existing agreements i.e. they would expire five years after either: i) the last publication of the full agreement; ii) one of the parties withdraws from the agreement; or iii) one of the parties proposes a revision of the agreement. From 1 September 2014 onwards, the expiry period of these clauses was further reduced from five to three

110. Cabinet Resolution 43/2014 of 27 June 2014.

111. Decree-Law 189/2012 of 22 August.

112. Law 55/2014 of 25 August.

113. Article 563 of Law 99/2003 of 27 August.

114. Article 482 of Law 23/2012 of 25 June.

years.<sup>115,116</sup> It is important to note that the expiry of such clauses does not necessarily imply the expiry of the collective agreement itself.

The reforms also altered the grace period (*sobrevigência*) which kicks in when one of the parties withdraws from a collective agreement. Prior to the reforms, this period could last for as long as the negotiations lasted, or for a minimum of 18 months when no negotiations were taking place. From 1 September 2014 onwards, this grace period was reduced to a minimum of 12 months and a maximum of 18 months.<sup>117</sup>

Finally, if the negotiations ended without new agreement, the old collective agreement would remain valid for another 60 days following the date on which one of the parties informed the relevant ministry (and the other party) of the failure to reach a new agreement (*ultra sobrevigência*). This period was also reduced from 1 September 2014 onwards from 60 to 45 days.<sup>118</sup>

Law 55/2014 of 25 August also envisaged a further reduction of the validity period of cessation clauses to two years and of the grace period to six months, upon positive evaluation by the social partners sitting on the Standing Committee for Social Dialogue (*Comissão Permanente de Concertação Social*) (where positive evaluation involves the consent of at least 50% of the employer organisations and 50% of the trade unions).

## Working-time arrangements

### *Working time accounts*

Portugal introduced a system of working-time accounts with the 2009 Labour Code (*Banco de Horas*) which allowed working time to be extended by four hours per day, but not exceeding a total of 60 hours per week and with a limit of 200 hours per year. Prior to the reform, however, working time accounts could only be set through collective agreements and applied exclusively to the workers covered by those agreements. The new regulations allow the employer to extend the working time accounts agreed as part of a collective agreement to all employees within a certain team, section or unit, as long as 60% of the employees concerned are covered by the collective agreement, or 75% of them agree to it.<sup>119</sup>

The reform also introduced individual working time accounts, which could be set by agreement between an employer and an employee, and which can be obtained by the latter's non-refusal (after two weeks) of a written proposal from the employer. This mechanism allows normal working time to be extended by two hours per day, up to a total of 50 hours per week, and the total increase in working hours cannot exceed 150 hours per year.<sup>120</sup>

---

115. In the absence of such clauses, collective agreements remain in force either: i) for the time period specified in the agreement; or ii) if no such time is specified, for one year (and renewable for one more year). Whether such clauses exist or not, collective agreements can also be terminated upon agreement between the signatory parties.

116. Law 55/2014 of 25 August.

117. Law 55/2014 of 25 August.

118. Law 55/2014 of 25 August.

119. Law 23/2012 of 25 June.

120. Law 23/2012 of 25 June.

The working time accumulated through these accounts can be compensated either: by an equivalent reduction in working hours; by an increase in holiday entitlement; or financially (or some mixture of the three).<sup>121</sup>

### ***Short-time work compensation***

A number of changes were also introduced to simplify the procedures required for employers wishing to implement short-time work schemes, such as temporary reductions in working time or temporary lay-offs (*redução temporária do período normal de trabalho ou suspensão do contrato de trabalho*).<sup>122</sup> The notice period for employers to inform workers of the measure to be applied was reduced from ten to five days, with a possibility to implement immediately if the works council (or the majority of workers concerned) agrees. In addition, the workers' representative body can no longer oppose an extension of the short-time work scheme, as long as the employer follows the necessary communication procedures. The reform also put in place some additional measures to protect workers (e.g. to avoid the dismissal of workers immediately following the end of the scheme) and gives them an increase in pay in case they attend a training course during the short-time work period (0.3 x IAS, divided equally between the employer and employee).

### ***Reductions in holiday entitlements***

Four public holidays were abolished by the reforms (from 1 January 2013 onwards), reducing the total number of bank holidays per year from 15 to 11.<sup>123,124</sup> In addition, workers who had not been absent during the previous year, or only had a small number (<3) of justified absences, were previously entitled to 1-3 extra days of annual leave. This entitlement was also revoked by the revision of the Labour Code (again, from 1 January 2013 onwards). The reward for lack of unjustified absences was instead replaced by a punishment for unjustified absence: an unjustified absence on either a Monday, Friday, or immediately preceding or following a public holiday, will now entail the loss of two days of wages. Furthermore, employers can now unilaterally decide to close for business for five consecutive days during Christmas, or for one day between the weekend and a bank holiday which falls on either a Tuesday or Thursday, and take this out of a worker's annual leave entitlement.

## **Wages**

In addition to freezing extensions of collective agreements: i) public sector wages were frozen/cut; ii) the national minimum wage was frozen; and iii) overtime pay and other compensation was reduced.

### ***Public sector wages***

In 2011, the wages of civil servants earning more than EUR 1 500 were cut (by between 3.5% and 10%). The government intended to further cut public sector wages by: i) suspending the 13<sup>th</sup> and 14<sup>th</sup> monthly salary payments for those workers with monthly salaries of EUR 1 100 or more; ii) suspending the equivalent of one of those payments for workers with monthly salaries between EUR 600 and EUR 1 100. However, Portugal's Constitutional Court ruled that these cuts were unconstitutional and

121. Law 23/2012 of 25 June.

122. Law 23/2012 of 25 June.

123. Law 23/2012 of 25 June. The law further specified that this measure will be re-evaluated after a period of five years. The new XXI Constitutional Government has approved plans to re-introduced all four bank holidays from 2016 onwards.

124. Law 23/2012 of 25 June also tried to enforce an equivalent reduction (of up to three days) in the additional holiday entitlements contained in collective agreements and employment contracts signed after 1 December 2003 and prior to 1 August 2012 – but the Constitutional Court rules this to be unconstitutional (Decision no. 602/2013).

that payment of bonuses should be resumed in 2013. These cuts were nevertheless implemented in 2012. In addition, in 2013, the government increased the working hours of public sector workers from 35 to 40 hours per week, without any increase in pay.

Further adjustments to public sector wages were introduced in the 2014 budget. Article 33 of the budget law cuts the total gross pay of public sector employees earning between EUR 675 and EUR 2 000 per month by 2.5% to 12% (progressively), and by 12% for all public sector wages above EUR 2 000. These wage cuts, together with other articles of the Budget Law concerning pensions and unemployment benefits, were ruled unconstitutional by the Portuguese Constitutional Court on 31 May 2014. As this ruling did not apply retroactively, the wage cuts were nonetheless implemented in the first and second quarters of 2014. Other provisions in the Budget Law with an impact on public sector wages, such as a reduction in overtime pay, an uncompensated increase in the weekly hours worked, and a ban on pay increases for promotions or bonuses for public sector managers, were not challenged by the Constitutional Court.

Given that this constitutional ruling had major implications for Portuguese public finances, a new package of austerity measures was introduced in July 2014, which imposed public sector wage cuts of between 3.5% and 10% on wages above EUR 1 500 per month. These cuts would be reversed over a period of four years, with a 20% reduction in the cut programmed in 1 January 2015 and further reductions in the next two years based on budget availability. The austerity measures also specified that the wage cuts had to be entirely reversed within four years. While the Constitutional Court approved the 2014 and 2015 wage cuts in August 2015, it ruled the proposed 2016 wage cuts unconstitutional.

### ***The minimum wage***

The value of the minimum wage was frozen in 2011 and in 2012 and 2013 stood at the level of 2011 (EUR 485). The minimum wage was increased to EUR 505 on 1 October 2014 (and until 31 December 2015). To help employers with existing minimum-wage workers absorb this increase, the government simultaneously announced a temporary decrease of 0.75 percentage points in employer social security contributions on minimum-wage workers who were hired no later than May 2014. This measure would be in place until January 2016.<sup>125</sup>

### ***Compensation for overtime work***

The reform reduced additional compensation for overtime work by half:<sup>126</sup> from 50% to 25% for the first hour of work; and from 75% to 37.5% for every subsequent hour carried out during a normal working day. For overtime work carried out on a weekly rest day or public holiday, additional compensation was reduced from 100% to 50%. In addition, the reform revoked the right of workers who performed overtime work to paid compensatory time off equal to 25% of the number of overtime hours carried out.<sup>127</sup>

Additional compensation for normal work carried out on a bank holiday in a firm not forced to shut on that day was halved from 100% to 50% (and the compensatory time off from work, should the employer opt for this *in lieu* of additional compensation, was reduced from a number of hours equal to the number of overtime hours supplied to half those hours).

In addition, the government suspended for a period of two years all clauses regarding overtime pay and compensatory time off contained in collective agreements and employment contracts signed prior to

125. Decree-Law 154/2014 of 20 October.

126. Law 23/2012 of 25 June.

127. The revision of the Labour Code kept the right to paid compensatory time off (equivalent to the number of hours of overtime carried out) if the overtime: i) impeded the worker from taking 11 hours of daily rest between two working days; or ii) was carried out on a compulsory weekly rest day.

the date on which the new rules entered into force (i.e. 1 August 2012).<sup>128</sup> This suspension was later extended until 31 December 2014.<sup>129</sup>

### Unemployment benefits

On 1 April 2012, a number of changes were introduced to unemployment benefits which aimed to: i) increase access to those benefits; while ii) reducing their generosity (both in terms of their replacement rate and duration).<sup>130</sup>

- Access to unemployment insurance (*subsídio de desemprego*) was increased by easing the employment conditions that a worker needed to satisfy in order to receive the benefit from 450 to 360 days of employment over the past 24 months preceding the unemployment spell. The employment condition for receipt of unemployment assistance (*subsídio social de desemprego*) was maintained at 180 days over the past 12 months.
- The maximum amount of unemployment insurance was reduced from 3 to 2.5 times the social support index (*indexante dos apoios sociais – IAS*)<sup>131</sup> (while it can never, as before, exceed 75% of the average salary over the 12 months period ending 2 months before unemployment).
- A declining replacement rate rule was introduced: after six months (180 days), unemployment insurance would now be reduced by 10% to encourage recipients to actively look for work.
- There was a temporary increase of 10% in the unemployment insurance of households with children where both parents are in receipt of unemployment benefit (equally applicable to single-parent families) – valid between 1 April 2012 and 31 December 2012.<sup>132</sup>
- Maximum benefit duration of unemployment insurance and assistance was cut from 900 to 540 days – although additional increments based on contributory history were maintained, which means that benefit duration for those with a long contribution history (and especially those aged over 50) could exceed this maximum (see Table A2). This new rule was not applicable, however, to the first unemployment spell after the date on which the law entered into force (in which case the old rules would continue to apply). The minimum duration of

128. Law 23/2012 of 25 June also declared void all clauses of collective agreements and employment contracts signed prior to 1 August 2012 and which concern compensatory time off for overtime work carried out on a working day, a complementary weekly rest day, or on a bank holiday. However, the Constitutional Court ruled this change to be against the Constitution (Decision no. 602/2013). Similarly, Law 23/2012 stated that from 1 August 2014 onwards (i.e. two years after the new law entered into force), all additional compensation for overtime work specified in collective agreements and employment contracts would be reduced by half (though not below the rates set by Law 23/2012). Again, however, the Constitutional Court ruled that this change was unconstitutional (Decision no. 602/2013).

129. Law 48-A/2014 of 31 July.

130. Decree-Law 64/2012 of 15 March.

131. Until 2006, welfare benefits in Portugal were determined in relation to the minimum wage. This link meant that increases in the minimum wage had a significant impact on public finances. This is why, in 2007, Portugal introduced the social support index (IAS) to serve as the reference for the determination of welfare benefits. The IAS was initially set at the value of the minimum wage, however it has been frozen at EUR 419.22 since 2009 (with no adjustments for inflation), meaning that it has significantly lost in purchasing power.

132. All unemployment assistance which ran out between 1 January and 31 December 2009 was extended by another six months as a temporary, crisis-related measure (Decree-Law 68/2009 of 20 March).

unemployment spells before and after the reform (without additional increments based on contributory history) are shown graphically in Figure A1.

- The duration of unemployment assistance for those who had already received unemployment insurance was increased for those aged 40 or over. Whereas previously, they would have received unemployment assistance for half the time they had received unemployment insurance for, they would now receive unemployment assistance for the same amount of time (although this was only applicable from the second spell of unemployment after the date on which the new law entered into force).
- In order to incentivise a return to work, the government also introduced a new measure which allows individuals who had: i) been unemployed for at least six months<sup>133</sup> and ii) had at least six months of entitlement to unemployment benefit left,<sup>134</sup> to keep part of their unemployment benefit if they accept a full-time job with earnings lower than the value of their unemployment benefit.<sup>135</sup> The amount that an individual is entitled to keep is calculated in accordance with the following rules: 50% of the individual's unemployment benefit during the first six months of employment (capped at EUR 500 per month); and then 25% of the individual's unemployment benefit for the following six months (capped at EUR 250 per month). The duration of the subsidy cannot exceed the remaining length of time for which the individual is entitled to unemployment benefit, and is capped at 12 months. The measure could initially not be combined with any of the wage subsidies available, although this was later changed.<sup>136,137</sup>

In addition to the above, the government introduced a contributory system of unemployment protection for the self-employed who work mainly with only one contracting entity<sup>138</sup> – i.e. those self-employed receiving at least 80% of their annual income from a single employer. To access the benefit, the individual needs to have exercised his/her self-employment activity (with the necessary contributions) for a minimum of 720 days (24 months) over the 48 months preceding the date of termination of the service agreement. The daily subsidy amount is calculated using the formula  $[(E \times 0.65)/30 \times P]$ , where E is the self-employed income bracket of the worker at the time the service agreement was terminated, and P represents the proportion of the individual's income that originated from that employer – with upper limits identical to those applied to normal unemployment insurance. The duration of the subsidy depends on the age of the beneficiary and is as described in Table A2. The unemployment protection system for these self-employed workers is financed through a 5% tax paid by employers. The system will be evaluated after two years of operation.

133. This was later reduced to three months, with no minimum for individuals aged 45 or over (Ministerial Ordinance 26/2015 of 10 February).

134. This was later reduced to three months (Ministerial Ordinance 26/2015 of 10 February).

135. Ministerial Ordinance 207/2012 of 6 July.

136. Ministerial Ordinance 26/2015 of 10 February.

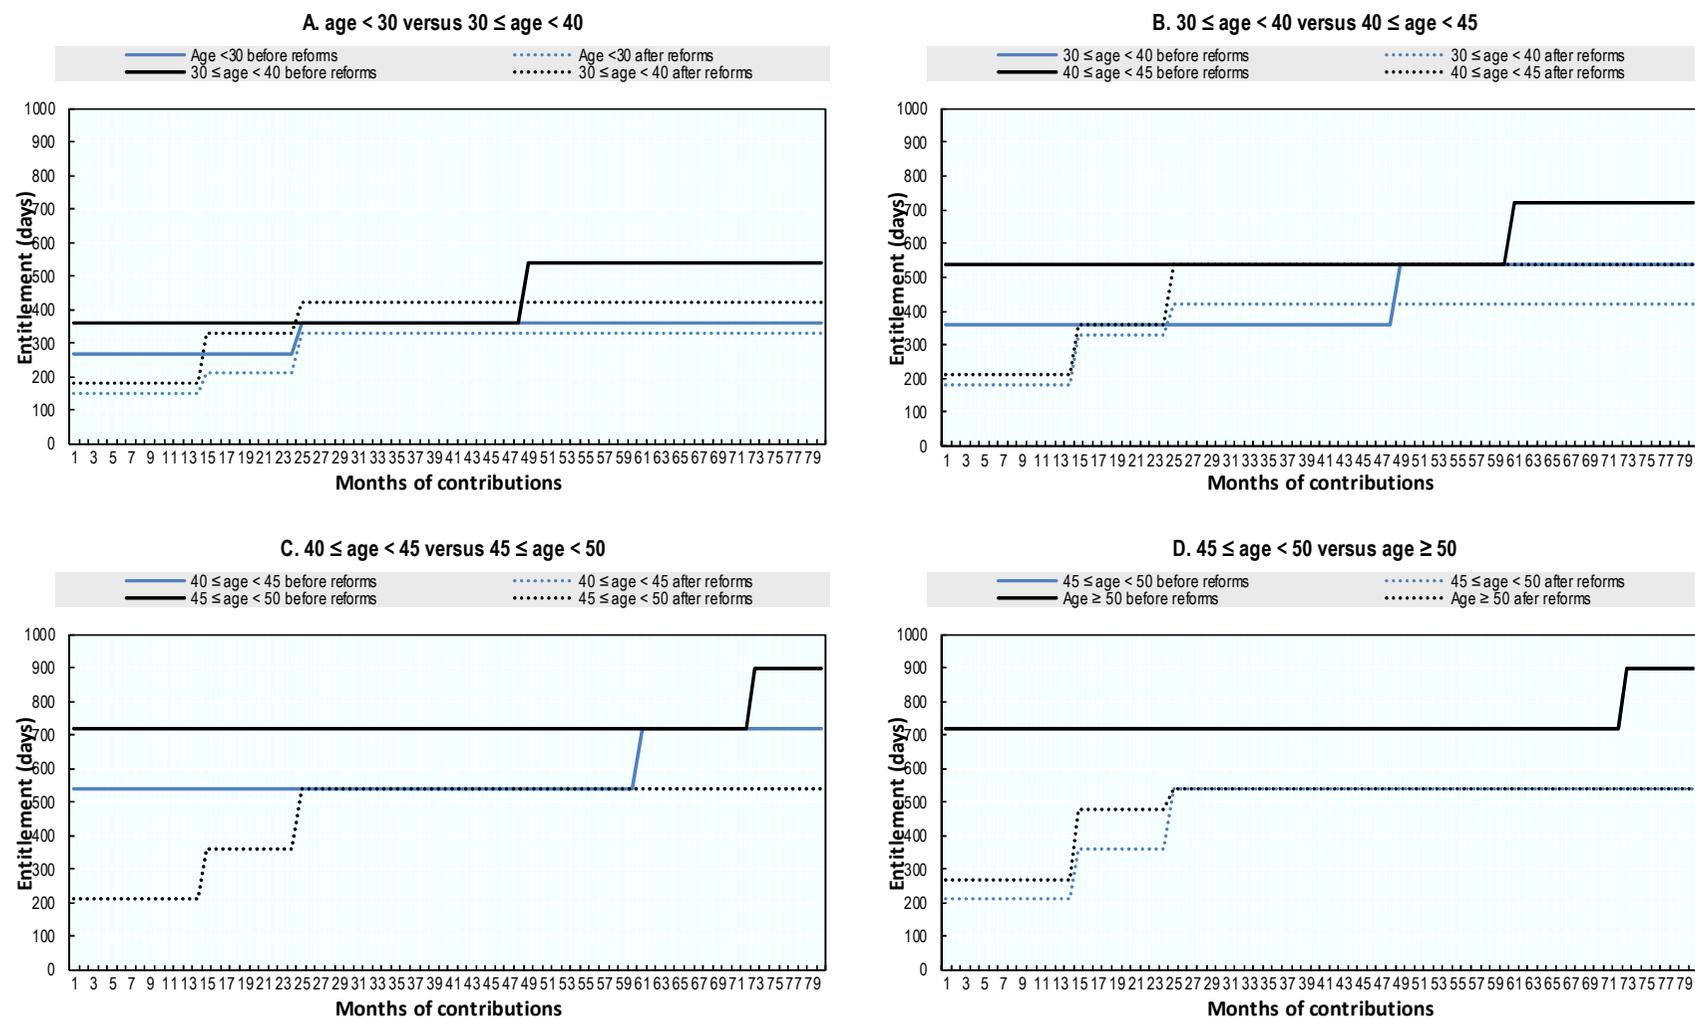

137. Note that it was already possible prior to the reforms to combine part-time work and receipt of unemployment benefits (*subsídio de desemprego parcial*). Unemployment benefit recipients who found part-time work (between 20%-75% of normal full-time working hours) with earnings below their current unemployment benefit were entitled to keep part of their unemployment benefit (calculated as the difference between 1.35 times the unemployment benefit and the part-time earnings) – Decree-Law 220/2006 of 3 November.

138. Decree-Law 65/2012 of 15 March.

Table A2. Changes in unemployment benefit regulations

Old rules				New rules			
Age	Contributions (months)	Entitlement (days)	Increment based on contribution history	Age	Contributions (months)	Entitlement (days)	Increment based on contribution history
Age < 30	≤ 24	270	+ 30 days for every 5 years of contributions	Age < 30	< 15	150	+ 30 days for every 5 years over the past 20 years
	> 24	360		15 ≤ x < 24	210	+ 30 days for every 5 years over the past 20 years	
30 ≤ age < 40	≤ 48	360	+ 30 days for every 5 years of contributions over the past 20 years	Age < 30	≥ 24	330	+ 30 days for every 5 years over the past 20 years
	> 48	540		30 ≤ age < 40	< 15	180	+ 30 days for every 5 years over the past 20 years
				15 ≤ x < 24	330	+ 30 days for every 5 years over the past 20 years	
40 ≤ age < 45	≤ 60	540	+ 30 days for every 5 years of contributions over the past 20 years	30 ≤ age < 40	≥ 24	420	+ 30 days for every 5 years over the past 20 years
	> 60	720		40 ≤ age < 50	< 15	210	+ 45 days for every 5 years over the past 20 years
Age ≥ 45	≤ 72	720	+ 60 days for every 5 years of contributions over the past 20 years	40 ≤ age < 50	15 ≤ x < 24	360	+ 45 days for every 5 years over the past 20 years
	> 72	900		Age ≥ 45	≥ 24	540	+ 45 days for every 5 years over the past 20 years
				Age ≥ 50	< 15	270	+ 60 days for every 5 years over the past 20 years
				15 ≤ x < 24	480	+ 60 days for every 5 years over the past 20 years	
				≥ 24	540	+ 60 days for every 5 years over the past 20 years	

Figure A1. Minimum unemployment duration before and after the reform (without increments based on contributory history)

## Activation

### *Modernisation of the Public Employment Service*

In 2012, the government launched a programme for the modernisation of the Public Employment Service (*Programa de Relançamento do Serviço Público de Emprego*) – see Box A1.<sup>139,140</sup> Many of these measures aimed to strengthen Portugal’s activation strategy – in particular the reporting requirements and referrals to active labour market measures of two groups of jobseekers: i) those aged 45+; and ii) those unemployed for six months or over (*convocatórias*).

#### Box A1. Modernisation of the Public Employment Service: Goals and measures

The PES modernisation programme aimed to: i) strengthen the employability of jobseekers; ii) better capture existing job opportunities; iii) improve co-operation between stakeholders; iv) modernise information systems; v) adopt a more systematic approach to active labour market policies (ALMPs); vi) improve the coherence between active and passive labour market policies; vii) regularly evaluate the performance of local PES offices; and viii) re-organise the PES network. A series of measures were outlined under each of these objective, as follows:

#### **Strengthening the employability of jobseekers:**

- Referral of jobseekers to either job search assistance or short-term training, within two weeks of registration.
- Priority referral of young jobseekers to job offers, internships or training in the context of the *Iniciativa Oportunidades para a Juventude*.
- PES staff to take up the role of “career manager” accompanying a certain number of jobseekers on an individual and continuous basis.
- More detailed and regularly updated individual action plans (*Plano Pessoal de Emprego*) and profiling.
- Measures to strengthen jobseekers’ skills through training programmes.
- Better identification of shortage occupations on the basis of difficult-to-fill vacancies.
- Retraining of jobseekers based on labour market needs.

#### **Better capturing existing job opportunities:**

- Setting up a job-registration mechanism, disseminated via social media, and integrated with an online vacancy database (*Portal NetEmprego*).
- Simplify the procedure for seeking employer authorisation to publish their vacancies on the *Portal NetEmprego* webpage.
- Publicly-available electronic register of all vacancies registered with the PES.

#### **Stakeholder co-operation to place jobseekers:**

- Regular collaboration between Job Centres (*Centros de Emprego*), temporary work agencies, and private employment agencies to improve, among others, information about job vacancies.
- Promote partnerships between Job Centres and employer associations to facilitate the registration and treatment of their members’ job vacancies.
- Stronger partnerships with the PES from other countries.

139. Cabinet Resolution No. 20/2012 of 9 March.

140. The Public Employment Service in Portugal is called the *Instituto de Emprego e Formação Profissional* (IEFP).

- Stronger integration with the EURES network.
- Establish partnerships with private employment agencies for placing jobseekers not in receipt of unemployment insurance or assistance.
- Carry out pilot projects based on best practices from around Europe.

**Modernise information systems:**

- Re-design the website (*Portal NetEmprego*).
- Improve the electronic registration of the unemployed, including the possibility to upload individual action plans.
- Implement a system for arranging interviews through e-mail and/or text messages.
- Breathe new life into the *Serviços de Atendimento Interativos* (SAI) [interactive customer service].
- Better matching between jobseekers and vacancies based on the available information.

**A more systematic approach to ALMPs:**

- Classification of ALMPs into five categories: employment incentives and direct job creation; internships; social work; self-employment and entrepreneurship support; training.
- Consolidate ALMPs and clearly define their objectives and the conditions under which they should be administered.
- Train “career managers” in the use of ALMPs.
- External evaluation of the effectiveness of ALMPs.

**Improve the coherence of active and passive labour market policies:**

- Mandatory meetings with PES case workers for unemployment benefit recipients aged 45+ and referral to ALMPs to strengthen their employability and/or promote their return to work.
- Referral of those receiving unemployment benefit for six months or more to active labour market policies.
- Reduce fraud in active job search activities (i.e. benefit recipients who attend job interviews just to fulfil the requirements for continued benefit receipt) through accompanied interviews.
- Enable jobseekers to keep part of their unemployment benefit while accepting full-time job offers.

**Create permanent evaluation mechanisms of local PES offices:**

- Introduce an efficiency rating system of local PES offices.
- Carry out customer satisfaction surveys (particularly among the unemployed).
- Evaluation of placement efforts and control of job search activity.

**Restructure the current network of Job Centres and Vocational Training Centres (*Centros de Formação Profissional*):**

- Merging of Job Centres, creating larger local offices that cover a greater territory.
- Merge Job Centres and Professional Training Centres to form Employment and Professional Training Centres (*Centros de Emprego e de Formação Profissional*).
- Develop a human resources strategy to strengthen resource allocation in local offices.
- Eliminate duplication in tasks between different local offices.

### *Private employment and temporary work agencies*

The government also made it easier to set up private employment and temporary work agencies:<sup>141</sup> prior authorisation is no longer required and was replaced by simple prior communication. The alteration to the law also eliminated the incompatibility between the activities of temporary work and private employment agencies, and the deposit required to set up an agency was cut by half. While there were also plans to allow the PES to contract out some of its activities to private employment agencies, in practice this still has not materialised.

### **Hiring subsidies**

During the crisis period, a number of hiring subsidies were introduced, which were revised on a number of occasions and, eventually, merged into one programme.<sup>142</sup>

### *Estímulo 2012*

The strengthening of activation measures was accompanied by the introduction of a new hiring subsidy, *Estímulo 2012*,<sup>143</sup> on 14 February 2012, and which was aimed at those who had been (registered) unemployed for at least six consecutive months. The subsidy was payable for a period of six months and was equivalent to 50% of the individual's wage over that period – or as high as 60% in case the person hired: i) was on a permanent contract; ii) was in receipt of income support (*rendimento social de inserção*); iii) was aged 25 or under; iv) had a disability; v) was low-skilled (i.e. had not completed basic education); or vi) was long-term unemployed (12 months or more). However, the overall monthly value could not exceed the IAS. While the subsidy could be combined with social security reductions that the employer was entitled to, it could not be used in combination with other direct employment support for the same position. In return for the subsidy, the employed needed to provide either: i) on-the-job training under the supervision of a specially assigned tutor; or ii) at least 50 hours of training with a certified training provider (during normal working hours). Only employers with at least five employees could apply for the subsidy, except where the employer opted for the second training option. The position offered needed to be full-time and on a contract lasting at least six months. Employers could not cumulate more than 20 subsidies and needed to prove that the subsidy was leading to net employment creation within the firm. In case the employer breached any of the conditions of the subsidy, it would need to be refunded (at least in part).

---

141. Law 5/2014 of 12 February.

142. Prior to the introduction of these new hiring subsidies, a programme (*Incentivos à Contratação*) was already in place which offered a temporary exemption from social security contributions for a period of up to three years as well as financial support for employers who hired an individual who was either long-term unemployed (one year or over) or a first-time jobseeker (aged 16-30). 100% of the social security contributions were exempted in case of a permanent contract, reduced to 50% in case of a temporary contract. In case of permanent contracts, employers were also entitled to financial support equal to 12 times the minimum wage applicable for that activity (Decree-Law 89/1995 of 6 May). This programme has been changed a number of times since its introduction. Currently, the programme consists in an exemption from employer social security contributions for the duration of three years (or of the contract, whichever is shorter) for employers who hire, on an open-ended contract, an individual who was either long-term or first-time jobseeker.

143. Ministerial Ordinance No. 45/2012 of 13 February.

### ***Estímulo 2013***

On 14 April 2013, a revised programme (*Estímulo 2013*) replaced *Estímulo 2012*.<sup>144</sup> The coverage of the programme was extended to a larger group of potential beneficiaries. In particular, those who had been unemployed for three consecutive months could now also benefit from the programme if they fulfilled one of the following conditions: i) they were low-skilled (i.e. had not completed basic education); ii) they were aged 45 or over; iii) they were single parents; iv) they lived in a workless household. In addition, those who had not been registered with social security (and were not studying) – i.e. inactive – for the past 12 months were now also eligible. The higher value of the subsidy (i.e. 60% of wages instead of 50%) was now also paid in case the hired worker was aged 50 or over, or in case his/her gender was under-represented in the particular sector of activity of the employer. Additional incentives were put in place to encourage employers to either offer a permanent contract to start with or convert a subsidised temporary contract into a permanent one. In the first case, the subsidy was awarded for a period of 18 months (instead of six) and the maximum monthly value of the subsidy could be 1.3 x IAS. In the second case, a conversion reward equivalent to an additional nine months (capped at nine times the IAS) would be paid. Some additional, smaller changes included: i) an upper limit of 25 subsidies per employer in the case of fixed-term contracts, and no upper limit in the case of open-ended contracts; ii) external training did not necessarily have to be carried out during working hours (although there then needed to be an equivalent reduction in working hours); and iii) the subsidy could now also be paid (proportionately) to part-time workers.

### ***Apoio à Contratação via Reembolso da TSU***

In the context of *Impulso Jovem*, the government launched the *Apoio à Contratação via Reembolso da TSU*<sup>145</sup> – a reduction in social security contributions targeted at long-term unemployed (12 months or more) youth (aged 18-30). These youth could be hired either on a permanent or on a temporary contract of at least 18 months. The subsidy, payable for 18 months, consisted in: a 100% waiver of the Single Social Tax (Taxa Social Única) in case of a young person hired on a permanent contract; and a 75% waiver in case the contract was temporary. Employers could not benefit from more than 20 subsidies. The maximum value of the reimbursement could not exceed EUR 175 per month. This measure could be used in combination with *Estímulo 2012*. The programme was launched on 4 August 2012. As with the *Estímulo* programme, there was a requirement of net job creation by the employer.

The programme was reviewed on 14 February 2013.<sup>146</sup> One of the most important changes was the extension of the coverage of the programme to include: i) young people unemployed for at least six months (instead of the previous 12 months); and ii) young people who had been inactive (but not studying) since leaving school and for at least 12 months. The programme was also extended to part-time contracts.

### ***Apoio à contratação de desempregados com idade igual ou superior a 45 anos via reembolso da TSU***

In February 2013, an *Apoio à Contratação via Reembolso da TSU* was created for unemployed individuals aged 45 or over.<sup>147</sup> The programme was virtually identical to the one for young people, except that the maximum value of the reimbursement was higher (EUR 200 per month instead of EUR 175).

144. Ministerial Ordinance 106/2013 of 14 March.

145. Ministerial Ordinance 229/2012 of 3 August.

146. Ministerial Ordinance 65-A/2013 of 13 February.

147. Ministerial Ordinance 3-A/2013 of 4 January, and revised by Ministerial Ordinance 97/2013 of 4 March.

### ***Apoio à contratação via Reembolso da TSU***

From July 2013 onwards, the two hiring incentives through reductions in social security contributions (*Apoio à Contratação via Reembolso da TSU* and *Apoio à contratação de desempregados com idade igual ou superior a 45 anos via reembolso da TSU*) were merged into one programme: *Apoio à contratação via Reembolso da TSU*.<sup>148</sup> There is no longer a minimum period of unemployment necessary for individuals to become eligible for the programme, and the maximum amount of the reimbursement has been equalised across all target groups (EUR 200). In addition, the programme has been extended to individuals aged 31 to 44 as long as they fulfil one of the following criteria: i) they are low-skilled (i.e. have not completed basic education); ii) they are single parents; or iii) they are in a workless household.

### ***Medida Estímulo Emprego***

All hiring subsidies cited above were merged into one programme, *Medida Estímulo Emprego*, from 25 July 2014 onwards.<sup>149</sup> In their current state, these subsidies have the following characteristics:

- Eligible individuals are those unemployed registered with the PES and who fulfil one of the following conditions:
  - Are in receipt of unemployment benefit
  - Are in receipt of income support
  - Have been unemployed for at least 60 consecutive days (in case of the unemployed aged 30 and under, or 45 and over), or inactive for the past 12 months
  - Have been unemployed for at least six consecutive months
  - Are living in a workless household
  - Are single parents
  - Have a disability
  - Are either a victim of domestic violence; or ex-convicts; or re-habilitated drug users
- Conditions on employers:
  - Offer a contract (full- or part-time; permanent or temporary, but of at least six months)
  - Generate net employment creation
  - Provide training during the period of the subsidy, either i) work-based under the supervision of a specially assigned tutor, or ii) externally in a certified training agency and for at least 50 hours
  - The person hired on a subsidy cannot have worked for the employer for the past 24 months
  - Cannot take on more than 25 subsidised workers on temporary contracts (but no limit on open-ended contracts)
- Value of the subsidy:
  - For temporary contracts: 80% of the IAS x (number of full months of the contract) / 2, capped at 80% of the IAS x 6. The 80% is replaced by 100% for the unemployed who are:

148. Ministerial Ordinance 204-A/2013 of 18 June.

149. Ministerial Ordinance 149-A/2014 of 24 July.

- ❖ Long-term unemployed (12 months or over)
  - ❖ Young (<30)
  - ❖ 45 or over
  - ❖ In receipt of unemployment benefit
  - ❖ Single parents
  - ❖ Living in a workless household
  - ❖ Either victims of domestic violence; or ex-convicts; or re-habilitated drug users
  - ❖ Have a disability
  - ❖ In receipt of income support
- For open-ended contracts: 110% x IAS x 12
  - In case of part-time contracts, the subsidy is calculated proportionally (on the assumption of a standard week of 40 hours)
  - In case a subsidised temporary contract is converted to a permanent one, the employer is entitled to the 6 x IAS paid at the percentage previously applicable (80% or 100%).

Table A3 summarises the main changes to these hiring subsidised over the past few years.

More recently, Ministerial Ordinance 84/2015 of 20 March introduced a new, financial incentive for the “Promotion of Gender Equality in the Labour Market” which consists in an increase in the value of the *Estímulo Emprego* of 20% (for a temporary contract) or 30% (in case of a permanent contract or conversion) in case the employer hires a worker from a sex that is under-represented in that particular profession (i.e. represents less than a third of all workers in that profession).

## Subsidised internships

In addition to the hiring subsidies, the government introduced a number of new subsidised internship programmes, or changed existing ones.

### *Programa de Estágios Profissionais*

In February 2011, the subsidised internship programme (*Estágios Profissionais*)<sup>150</sup> was revised. It became targeted at: i) young people (aged 30 or under) who had completed levels 4, 5, 6, 7 or 8 of the National Qualifications Framework (QNQ); or ii) people aged 30+ who had been inactive for the past 12 months and who had completed levels 2, 3, 4, 5, 6, 7 or 8 of the QNQ less than three years ago; or iii) people with disabilities, regardless of their age. Internships lasted nine months and the intern was given a bursary commensurate with his/her level of education: 1 x IAS for those with level 2 of the QNQ; 1.2 x IAS for those with level 3; 1.3 x IAS for those with level 4; 1.4 x IAS for those with level 5; and 1.65 x IAS for those with levels 6, 7 or 8. The intern was also entitled to a food allowance. These costs were partially covered by the PES as follows: 75% for employers with fewer than ten employees; 65% for employers with between ten and 250 employees; and 40% for employers with more than 250 employees. The PES covered an additional 10% in case the intern had a disability. The employer remained responsible for the payment of taxes and social security contributions. Employers who, over a period of two years, had not absorbed at least one third of their interns into their regular workforce were not entitled to any further internships for a period of one year. In January 2013,<sup>151</sup> the *Estágios Profissionais* were extended to the unemployed who were either single parents or part of a workless household, irrespective of their age, and the PES covered 100% of the bursaries paid to these interns.

### *Passaportes Emprego*

Against the backdrop of the strategic plan to tackle youth unemployment, *Impulso Jovem*, launched in June 2012, the government set out the details of one of its measures, the *Passaportes Emprego*, in July 2012.<sup>152</sup> The *Passaportes Emprego* were a set of subsidised internship programmes aimed at youth (primarily aged between 18 and 30) who had been unemployed for at least four months. They lasted for a period of six months and needed to take place in one of the disadvantaged regions of Portugal.<sup>153</sup> Employers needed to provide training of at least 50 hours through a certified training centre, and needed to pay the intern a bursary commensurate with his/her level of education: 1.65 x IAS for those who had completed tertiary education; 1.25 x IAS for those who had completed at least secondary education; 1 x IAS for those who had not completed secondary education. In addition, the employer was expected to pay a food allowance and transport expenses. The PES would cover some (or all) of these expenses: 100% for the first intern if the employer had ten or fewer employees and 70% for the second; 70% also in case the employer had more than ten employees. In case the internship was converted into an open-ended contract, the employer would receive a reward equal to six times the monthly value of the bursary.<sup>154</sup>

150. Ministerial Ordinance 92/2011 of 28 February.

151. Ministerial Ordinance 3-B/2013 of 4 January.

152. Ministerial Ordinance 225-A/2012 of 31 July.

153. This geographical restriction was due to the fact that the measures included in the *Impulso Jovem* were financed by the European Social Fund. In reality, the *Passaportes Emprego* were also implemented in Lisbon, financed through the PES budget.

154. It is important to note that the *Passaporte Emprego* has a number of variations depending on the specific target group, and not all of these have been described here. For more detail, the reader is therefore referred directly to the Ministerial Ordinance itself.

### ***Harmonisation between Passaportes Emprego and the Estágios Profissionais***

In February<sup>155</sup> and March<sup>156</sup> 2013 the *Passaportes Emprego* and the *Estágios Profissionais* were more closely aligned with one another. Whereas the *Passaportes Emprego* would be aimed primarily at unemployed youth aged 18-25, the *Estágios Profissionais* would cover the unemployed aged 25-30 as well those aged 30+ if they have been inactive for the past year and obtained their qualification less than three years ago; or if they were single parents, living in a workless household, or had a disability. The duration of both programmes was increased to 12 months and the value of the bursaries were homogenised: 1 x IAS for those with level 2 of the QNQ; 1.2 x IAS for those with level 3; 1.3 x IAS for those with level 4; 1.4 x IAS for those with level 5; and 1.65 x IAS for those with levels 6, 7 or 8. The *Passaportes Emprego* were also extended to the whole of Portugal (being previously restricted to economically disadvantaged areas), the minimum unemployment spell durations for eligibility for the programme were eliminated, and the definition of training to be provided to the intern was broadened (it could now also be work-based).<sup>157</sup> Finally, the contributions of the PES for both programmes were revised as follows: 100% of the bursary for the first intern for employers with fewer than ten employees; 80% of the bursary for interns hired by employers with more than ten employees (as well as from the 2<sup>nd</sup> intern onwards in the case of employers with fewer than ten employees). In the case of the *Estágios Profissionais*, an additional 10% would be covered if the intern has a disability. In the case of the *Passaportes Emprego*, the employer would still be offered a financial reward if the internship was converted into an open-ended contract.

### ***Estágios Emprego***

*Passaportes Emprego* and *Estágios Profissionais* were replaced by *Estágios Emprego* from 18 July 2013 onwards.<sup>158</sup> The programme is aimed primarily at: i) youth aged 18-30 who are unemployed and registered with the Public Employment Service, and who hold a qualification of level 2-8 of the QNQ; as well as ii) those aged over 30 who are registered with the Public Employment Service, have completed a qualification of level 2-8 of the QNQ in the past three years, and have no social security record for the past 12 months. Individuals with a disability, those living in a workless household, and victims of domestic violence are also eligible, regardless of age and qualifications held. Internships last for a period of 12 months and interns are paid a bursary commensurate with their level of education (1 x IAS for those with level 2 of the QNQ; 1.2 x IAS for those with level 3; 1.3 x IAS for those with level 4; 1.4 x IAS for those with level 5; and 1.65 x IAS for those with levels 6, 7 or 8). 100% of this bursary is covered by the PES for first interns in firms with ten employees or less, and who are hired prior to 31 December 2014. In all other cases, 80% of the bursary is covered by the PES (increased to 90% if the intern has a disability).

### ***REATIVAR***

Ministerial Ordinance 86/2015 of 20 March introduces a new internship of six months (REATIVAR) aimed at the long-term unemployed aged over 30. The bursary received during the internship is in line with those of the *Estágios Emprego* covered by the PES: i) for 80% in the case of non-profit legal entities and for the first intern with an employer who has fewer than ten employees; ii) for 65% in all other circumstance. An additional 15% are covered in case the intern fulfils one of the following criteria: has

155. Ministerial Ordinance 65-B/2013 of 13 February.

156. Ministerial Ordinance 120/2013 of 26 March.

157. Note that there is no training requirement in the case of the *Estágios Profissionais*.

158. Decree 204-B/2013 of 18 June, as changed by Decree 375/2013 of 27 December and Decree 20/2014 of 30 January.

been unemployed for at least two years; is older than 45; has a disability; is a single parent; lives in a jobless household; is a victim of domestic violence; is an ex-convict; or is an ex-drug user in rehabilitation.

### ***Contratos Emprego-Inserção***

In place since 2009,<sup>159</sup> the Contrato Emprego-Inserção and Contrato Emprego-Inserção+ are subsidised internship programmes that aim to improve the socio-professional skills of disadvantaged unemployed individuals through a subsidised internship doing socially useful work. These internships can last up to 12 months and were initially aimed at the unemployed: with disabilities, aged 55+, who are ex-convicts, or who have been out of a job for more than a year (i.e. the long-term unemployed). There are two types of contract: the Contrato Emprego-Inserção is aimed at those who are in receipt of unemployment benefits; and the Contrato Emprego-Inserção+ is aimed at those receiving the guaranteed minimum income benefit (*rendimento social de inserção*).<sup>160</sup> Those in receipt of unemployment insurance receive a top-up equivalent to 20% of their unemployment benefits, while those in receipt of unemployment assistance receive a top-up equivalent to 20% of the IAS. In both these cases, and for private, not-for-profit organisations, the PES would cover 50% of these costs. Finally, those in receipt of just guaranteed minimum income benefit would receive a bursary equal to the IAS, covered 90% by the IEFP if the host institution is a private, not-for-profit organisation, and 80% if the host is a public entity (increased by an additional 10 percentage points in case the intern has a disability).

During the crisis, a few small changes were introduced to these programmes, primarily aimed at widening access to them:

- 1 June 2010: priority for participation in the programme is given to unemployed individuals whose income is equal or less than the minimum wage.<sup>161</sup>
- 19 April 2011: the bursary for unemployment insurance recipients is capped at 20% of the IAS.<sup>162</sup>
- 1 January 2014: prioritised groups now include those aged 45+ (as opposed to 55+); and the Contrato Emprego-Inserção+ is extended to those who do not receive either unemployment or guaranteed minimum income benefits, and who fulfil one of the following conditions: are long-term unemployed; or live in a workless household.<sup>163</sup>
- 31 January 2014: victims of domestic violence are included in the priority target group and, in case the individual receives unemployment benefit and is disabled, the PES covers 100% of the costs.<sup>164</sup>

### **Training programmes**

Two new, short-duration training programmes were introduced in 2013: *formação transversal* (a 25-hours training programme aimed at improving personal, communication, entrepreneurial and job search skills) and *Vida Ativa*.

159. Decree 128/2009 of 30 January.

160. Those that are simultaneously in receipt of unemployment benefits and the guaranteed minimum income benefit are eligible for the *Contrato Emprego-Inserção*.

161. Decree 294/2010 of 31 May.

162. Decree 164/2011 of 18 April.

163. Decree 378-H/2013 of 31 December.

164. Decree 20-B/2014 of 30 January.

### **Formação transversal**

*Formação Transversal – Ativação e Técnicas de Procura de Emprego* is a short module (25 hours) provided by the Public Employment Service which aims to boost the employability of job seekers by developing their personal, communication and job search skills.

### **Vida Ativa**

*Vida Ativa*<sup>165</sup> is targeted at: those who have been unemployed for six months or more; low-skilled unemployed (whose qualifications are below levels 1 or 2 of the QNQ); and those in jobless households. The intervention consists of part-time, short, modular training courses (lasting between 25 and 300 hours) during which the participant is expected to continue actively looking for work. Where possible, these training courses are supplemented with practical, work-based training for a period of 3-6 months (extended exceptionally to a period of 12 months). Where appropriate, the intervention may consist instead in the validation of existing skills. Participation in *Vida Ativa* should start no later than three months after registration with the Public Employment Service.

### **Youth**

#### ***Impulso Jovem***

In June 2012,<sup>166</sup> the government launches its strategic plan to tackle youth unemployment, *Impulso Jovem* (which would later turn into the Youth Guarantee), built on four pillars: internships (*Estágios Emprego*), hiring incentives (*Apoios à Contratação*), vocational training (*Formação Profissional*) and entrepreneurship support (*Empreendedorismo*). More specifically, the measures announced as part of this plan include:

- *Passaporte Emprego*: internships for unemployed youth, combined with a hiring incentive should the employer subsequently hire the young person on an open-ended contract.
- Incentives for hiring long-term unemployed youth through reductions in social security contributions.
- *Passaporte para o Empreendedorismo* and *Portugal Empreendedor*: covering a range of interventions to promote youth entrepreneurship and firms hiring highly-skilled youth who have been unemployed for four months or more.
- *COOP Jovem*: supporting the creation of co-operatives through direct financial support to each worker aged between 18 and 30 years, and who have completed the first cycle of basic education.
- Development of a national microcredit programme which provides technical support and training of the entrepreneur during the first years of operation, giving priority to individuals aged between 16 and 34 and who have been registered as unemployed for at least four months.<sup>167</sup>
- Investment support, including a component to facilitate access to finance for small- and medium-sized enterprises.

165. Decree 203/2013 of 17 June.

166. Cabinet Resolution 51-A/2012 of 14 June.

167. The microcredit programme already existed (Ministerial Ordinance 985/2009 of 4 September). The Ministerial Ordinance 95/2012 of 4 April amended it to give priority to those aged 16-34 enrolled as unemployed in the PES for at least four months (the target group of the first edition of the *Impulso Jovem*).

One year later, the strategic plan was revised in an attempt to rationalise and simplify the various policy instruments.<sup>168</sup> In particular, with respect to hiring incentives, the link was made with *Estímulo 2013* and the *Apoio à Contratação via Reembolso da TSU*.

### ***Youth Guarantee***

At the end of 2013, the Portuguese Government announced the *Youth Guarantee*, which encompasses all measures cited above aimed at young people, as well as others.<sup>169</sup>

### ***Emprego Jovem Ativo***

The programme *Emprego Jovem Ativo* was introduced in September 2014<sup>170</sup> and is a six-months-long work experience/group apprenticeship programme which involves a co-ordinator, a highly-skilled unemployed youth (with a university degree) as well as 2-3 low-skilled unemployed youths (who have not completed basic education). Participants need to be aged between 18 and 29 and registered with the Public Employment Service. For low-skilled youth, the programme provides an opportunity to acquire a range of professional as well as soft skills. For high-skilled youth, the programme aims to provide an opportunity to gain management skills. For the duration of the programme, participants receive a monthly bursary (0.7 x IAS for low-skilled youths and 1.3 x IAS for high-skilled youths), covered entirely by the PES and there is no need for employers to contribute to social security.

---

168. Cabinet Resolution 36/2013 of 4 June.

169. Cabinet Resolution 104/2013 of 31 December.

170. Ministerial Ordinance 150-2014 of 30 July.

## ANNEX C

### THE IMPACT OF SEVERANCE PAY REFORMS IN PORTUGAL ON ON-THE-JOB SEARCH AND WORKER FLOWS

#### Introduction

As part of the labour market reforms, Portugal significantly reduced the severance pay entitlements of workers (and of new hires in particular – see Chapter 1 and Annex A for further detail). The primary objective of these reforms was to encourage a more efficient re-allocation of labour resources. With lower severance pay entitlements, workers might be less reluctant to switch jobs, resulting in increased on-the-job search and job-to-job flows. For employers, lower severance pay could increase both hiring and firing rates. However, as a result of grandfathering<sup>171</sup>, accumulated severance pay entitlements were preserved by the reform. One would therefore expect the largest (short-run) effects of the reform to be on hiring only (and possibly on the firing/job-to-job moves of new hires). In addition, because the reduction in severance pay was larger for permanent than for temporary contracts, one might expect to see an increase in the share of hiring that is on permanent contracts. At the same time, it is important to remember that severance pay was cut for both types of contract, and so the reform should have encouraged hiring on temporary as well as on permanent contracts.

Table C1 shows the implications of the reforms in terms of the average severance pay entitlements of existing and new workers, respectively, as well as by type of contract. For each of these breakdowns, the table shows three different severance pay estimates:

1. What severance pay would have been like under the old rules (“old”);
2. Actual severance pay the worker is currently entitled to (“actual”); and
3. What severance pay would be like if the new rules applied fully – i.e. without any grandfathering (“new”).

Box C1 provides further detail on how these severance pay indicators are derived, and some of the assumptions that needed to be made in the process.

---

171. Grandfathering refers to the exemption of some individuals from a new regulation that prohibits or restricts something. In the present case, many of the new severance pay rules applied to new hires only, and not to existing workers.

### Box C1. Construction of the severance pay variables for the analysis

Quarterly European Labour Force Survey (EU-LFS) data on start date, contract type and duration of temporary contracts were used to calculate the number of months of severance pay each individual is entitled to under the current/actual rules, as well as what they would be entitled to under the old and new rules, respectively. As the EU-LFS does not contain information on wages, the rules concerning the maximum base wage for the calculation of the severance pay entitlement (i.e. 20 times the minimum wage) could not be taken into account (although severance pay was still capped at 12 months). Given that only a very small fraction of employees have wages higher than 20 times the minimum wage, the severance pay calculation will not be strongly affected by this simplification.

The same methodology was applied to the annual *Quadros de Pessoal* (QP) data, which have the advantage that the exact survey and starting dates are known, making the calculation more precise. However, the QP data contain no information on the duration of temporary contracts, which made it necessary to assume that all temporary workers had contracts of less than six months.

Table C1 confirms that the first reform (1 November 2011) had no impact on the actual severance pay entitlements of existing workers, but did change the entitlements of newly hired workers substantially compared to what they would have received under the old rules (primarily as a result of the removal of the 3-month minimum severance pay entitlement). While the second reform (1 November 2012) did not change anything else for new hires, it lowered the rate at which severance pay entitlements of existing workers would be accumulated, and also introduced a cap. This explains the small drop in actual severance pay of existing workers compared to what they would have received under the old rules. Finally, the third reform (1 October 2013) had an impact on both new and existing workers by further reducing the rate at which severance pay would be accumulated. For existing workers, this led to another small reduction in average severance pay. For new hires, the average after the third reform is much lower than that observed after the previous two reforms because it reflects severance pay accumulated over a maximum of three months only.<sup>172</sup>

Table C1. Average severance pay entitlements (number of days) after each reform, by type of worker and contract type: Old, new and actual rules

		Permanent contracts			Temporary contracts		
		1 <sup>st</sup> reform	2 <sup>nd</sup> reform	3 <sup>rd</sup> reform	1 <sup>st</sup> reform	2 <sup>nd</sup> reform	3 <sup>rd</sup> reform
Existing employees	Old	363.93	371.26	365.14	73.92	76.5	60.65
	Actual	363.93	361.04	342.97	73.92	60.57	44.21
	New	202.97	207.08	140.58	53.15	53.79	38.62
New hires	Old	90	90	90	7.39	6.45	1.44
	Actual	5.60	5.01	0.35	4.46	4.01	0.83
	New	5.60	5.01	0.35	4.46	4.01	0.83

Note: Estimates are based on the European Labour Force Survey Q1 2011-Q4 2013. The averages in each column are calculated based on all individuals observed after the relevant reform, but before the next reform (or end of sample). For example, for the calculation of the values of the second reform, all individuals surveyed over the period 11/2012 to 9/2013 are included. New hires are defined as workers with tenure shorter than three months.

Source: OECD analysis based on the EU-LFS.

172. This is because the data used for these estimates stop in Q4 2013. Note that this will not matter for the regressions that are run later in this section because the explanatory variable used measures the percentage difference with what an individual would have received under the old rules (which will be equally low).

This annex presents some initial evidence on the impact that these changes in severance pay might have had on on-the-job search and worker flows. The results obtained here need to be interpreted with care because: i) the reforms were implemented very recently and their full impact on the labour market might not be observable yet; ii) the nature of the reforms means that it was not possible to identify clear treatment and control groups, and therefore the causality of the observed effects cannot be established with full certainty. That being said, three separate approaches are presented below, and the findings are surprisingly consistent with one another (as well as robust to a falsification exercise): the severance pay reforms appear to have had only a small effect on firing (which appears to be concentrated on new hires only); a positive effect on hiring (although this finding is less robust to the falsification test); and a positive effect on the share of hiring that is permanent. All these effects appear larger for small firms (with fewer than 50 employees). The estimates also suggest that workers most affected by the reforms are more likely to be engaged in on-the-job search. At the same time, there is some indication that workers in firms most affected by the reforms experienced lower wage growth. Overall, these results indicate that the reforms of severance pay in Portugal were beneficial for both worker reallocation and labour market duality. However, the findings are only preliminary and further research will be required to confirm them.

### **The impact of the severance pay reforms on on-the-job search and worker flows: Evidence from the European Labour Force Survey**

Table C1 summarised the estimated effects of the new severance pay rules on the average entitlements of different types of worker (existing employees and new hires) as well as by type of contract. The basic idea behind the analysis in this section is to exploit variation in the depth of these reforms (i.e. the percentage difference between the old and actual/new severance pay) and estimate its impact on the labour market outcomes of different individuals/occupations. For example, one would expect to observe a higher probability of on-the-job search for those individuals for whom the difference between actual severance pay and that which they would have received under the old rules is greatest. Similarly, employers might be more likely to fire workers for whom the reforms have meant the greatest reduction in severance pay (as measured by the difference between actual severance pay and what they would have been entitled to under the old rules). As far as hiring is concerned, employers will be more forward-looking and interested in the new rules (applying to new hires) rather than the actual rules (applying to existing workers). In this case, therefore, one would expect to see more hiring among employers where the difference in severance pay between the old and new rules is the greatest. Finally, one might expect to see an increase in the share of hiring that is on permanent contracts amongst those employers who saw a larger fall in severance pay for permanent workers than for temporary ones.

This section uses the EU-LFS to test the above hypotheses. The advantage of the EU-LFS (compared to the *Quadros de Pessoal* data discussed in the next section) is that observations are available on a quarterly basis (i.e. relatively frequently). On the downside, the data are not longitudinal so that individuals and employers cannot be followed over time. In addition (and as explained below), most of the analysis needs to be done at the more aggregated occupational level (as opposed to the firm as in the *Quadros de Pessoal*).

To analyse the impact of severance pay on the probability of on-the-job search, the following individual-level regression model is used:

$$Y_{it} = \beta_0 + \beta_1 \Delta \log(SP_{it}) + \sum_{c>1} \beta_c X_{cit} + \gamma_t + \mu_q + \varepsilon_{it} \quad (1)$$

Where  $Y_{it}$  is a dummy variable indicating whether individual  $i$  is engaged in on-the-job search at time  $t$ , and  $\Delta \log(SP_{it})$  is the percentage difference between the old and actual severance pay. The regression further controls for individual characteristics,  $X_{it}$  (age, gender, country of birth, region, educational

attainment, industry, occupation, tenure and contract type<sup>173,174,175</sup>), as well year ( $\gamma_t$ ) and quarter ( $\mu_q$ ) fixed effects.

While the on-the-job search analysis is run at the individual level, this is not possible for the regressions looking at hiring (the percentage of workers at time  $t$  with tenure less than three months) and employment outflows (the percentage of individuals who, at time  $t$ , had been unemployed or inactive for less than three months).<sup>176</sup> This is because, by definition, severance pay cannot be calculated when the individual is unemployed/inactive (i.e. tenure is non-existent/missing). For these outcome variables, the analysis is run at the occupation level (30 groups)<sup>177</sup> and the model becomes:

$$Y_{gt} = \beta_0 + \beta_1 \Delta \log(SP_{gt}) + \sum_{c>1} \beta_c X_{cgt} + \gamma_t + \delta_g + \mu_q + \delta_g \cdot \mu_q + \varepsilon_{it} \quad (2)$$

Where the explanatory variable,  $\Delta \log(SP_{it})$ , and the control variables are all transformed into within-group averages, and group fixed effects,  $\delta_g$ , as well as group-specific seasonal effects,  $\delta_g \cdot \mu_q$ , are added to the equation. In the case of hiring, the explanatory variable is defined as the percentage difference between the old and *new* severance pay (as opposed to the difference between old and *actual* severance pay used in the case of employment outflows).

The final model looks at the impact of the reforms on the share of hires that are permanent. The set-up is identical to the one in equation (2) and is run at the group-level, except that the explanatory variable now becomes the difference between the average  $\Delta \log(SP_{gt})$  for permanent workers and the average  $\Delta \log(SP_{gt})$  for temporary workers within an occupation. This is because, in making decisions about

- 
173. Controls for tenure and contract type are included to correct for composition effects. Without these, one concern might be that the occupation-level results are biased due to reverse causality (i.e. changes in the outcome variable having an impact on the explanatory variable  $\Delta \log(SP_{it})$ ). Indeed, given that  $\Delta \log(SP_{it})$  is defined as a within-group average, its value is determined not only by the severance pay rules, but also by the composition of employment. While the conclusions remain essentially unchanged when controlling for composition effects, the size of the coefficients is always smaller, suggesting that there may indeed be some reverse causality. Adding in an interaction between tenure and contract type has little effect on the results. In alternative models (not shown here) the composition effect was addressed by reweighting the data so that the composition remains constant at the average level throughout the time period analysed. These results were qualitatively very similar to the ones presented here.
174. The tenure groups are defined as: < 3 months, 3-6 months, 6-12 months, 1-2 years, 2-4 years, 4-6 years, 6-8 years, 8-10 years, 10-15 years, 15-20 years, 20-25 years, 25-30 years, and 30+ years. The contract type groups are defined as: permanent; temporary with a duration of less than six months; and temporary with a duration of six months or more.
175. Also controlling for the level of severance pay makes little difference to the results. This is not surprising given that both tenure and contract type (which jointly determine severance pay) are already included in the regression.
176. With the EU-LFS data, one can look at hiring (i.e. whether an individual has tenure shorter than three months). In this case, flows from all previous states are included (i.e. inactive, unemployed, or employed in another job). The EU-LFS also allows one to look at employment outflows. In this case, only moves into either inactivity or unemployment can be observed. So outflows are defined as individuals who have moved from employment into either inactivity or unemployment in the past three months. Note that, because these variables are defined at the occupation level, they can be interpreted as hiring and employment outflow rates.
177. Occupations are defined at the 2-digit ISCO level. Some 2-digit occupations are clustered (within the same 1-digit occupation) to ensure a sufficient number of observations. The occupation of a non-employed person is defined as the occupation of his/her last job.

whether to take on permanent or temporary workers, employers are likely to consider by how much severance pay under the new rules fell for permanent contracts compared to temporary ones.

Table C2 reports the estimated coefficients on the severance pay variable,  $\beta_1$ , for each different outcome using EU-LFS data for the period Q1 2011-Q4 2013.<sup>178</sup> The results can be interpreted as the percentage point change in the outcome of interest for a 1-percentage point increase in the difference in severance pay before and after the reform (or, in the case of the last column, of a 1-percentage point increase in the difference in severance pay reduction between permanent and temporary contracts). The results in Table C2 confirm the expected impact of a reduction in severance pay: i) on-the-job search increases; ii) hiring increases; and iii) the fraction of hiring on permanent contracts increases (although the coefficient is only marginally significant). By contrast, the impact on flows out of employment is insignificant.<sup>179,180</sup>

**Table C2. The impact of the severance pay reforms on on-the-job search and worker flows: Evidence from the EU-LFS**

	Individual level	Group level		
	On-the-job search	Employment outflows	Hiring	Share permanent hiring
$\Delta \log(\text{SP}_{gt})$ : old v. actual rules	0.075***	-0.037		
$\Delta \log(\text{SP}_{gt})$ : old v. new rules			0.131**	
$\Delta \log(\text{SP}_{gt}^{\text{perm}}) - \Delta \log(\text{SP}_{gt}^{\text{temp}})$ : old v. new rules				1.077*

Note: \*\*\* Significant at the 1% level, \*\* significant at the 5% level, \* significant at the 10% level. Robust standard errors clustered at the occupation-year level. Agricultural and public sectors excluded.

Source: OECD analysis based on the EU-LFS.

178. While earlier data is available, the analysis only starts in Q1 2011 because of a methodological break in the Portuguese Labour Force Survey.
179. The analysis presented in Table C2 considers all the reforms of severance pay simultaneously. Regressions have also been run on each of the reforms separately. While excluding the first or third reform has no substantial impact on the coefficients for on-the-job search and employment outflows, the exclusion of the first reform leads to a slightly lower and less significant coefficient on hiring. This confirms the importance of the first reform in encouraging hiring. The impact of the difference between permanent and temporary severance pay entitlement on the share of permanent workers becomes insignificant when excluding the third reform, which is consistent with the fact that severance pay entitlement for new workers became higher for temporary workers than for permanent workers following this last reform.
180. The interpretation of the size of these coefficients is not straightforward, but providing some population averages may help. The average difference between old and actual severance pay is 5.3%, while 6.6% of workers are engaged in on-the-job search. Against this background information, lowering severance pay by 1 percentage point would increase on-the-job search by 0.075 percentage points. Turning to hiring, 3.8% in each quarter are new hires. The average difference between old and new severance pay is 29.6% and the results indicate that a 1-percentage point increase in this gap results in a 0.13-percentage point increase in the hiring rate. This is a relatively large effect, but may be consistent with the fact that unemployment in Portugal in the recovery has been falling considerably faster than what would have been predicted based on the past relationship between unemployment and GDP growth (see Chapter 3). In addition, this coefficient should be seen as an upper bound on the possible effect of the reform. More realistically, assuming that there is no effect on the occupation with the smallest change in severance pay and anchoring all estimates on this occupation, the reform would expect to result in a 0.23-percentage point increase in the hiring rate on average. Finally, 17.7% of hires are on permanent contracts, and the average difference between the reduction in permanent and temporary severance pay is 8.8 percentage points. The results show that a 1-percentage point increase in this difference would result in 1-percentage point increase in hiring on permanent contracts.

While there is no clear identification strategy which would allow these results to be interpreted as causal, a robustness check is run which does provide additional confidence that they may be attributed to the reform. More specifically, as a falsification exercise, the same regressions are run again, but tenure levels and contract type are randomised for each individual (while keeping their labour market outcomes unchanged).<sup>181</sup> Using these random tenure levels and contract types, a new explanatory variable measuring the difference between the pre- and post-reform severance pay systems is estimated. If the relationships observed in Table C2 persist despite the randomisation, then one should worry that those effects are not truly caused by the reform. Table C3 shows that, with the randomised severance pay variable, all the coefficients that were significant in Table C2 turn insignificant, while the insignificant coefficient on outflows becomes significant, the sign is the opposite of what the theory would predict. Perhaps the only coefficient for which the falsification exercise is less convincing is the one on hiring: while the estimate turns insignificant, the size of the coefficient is very similar (even slightly larger) to the one obtained in Table C2. Overall, however, the results from this falsification exercise support the argument that the effects observed are linked to the reform.

Table C3. **The impact of the severance pay reforms on on-the-job search and worker flows: Falsification exercise with randomised tenure and contract type (EU-LFS)**

	Individual level	Group level		
	On-the-job search	Employment outflows	Hiring	Share permanent hiring
$\Delta \log(SP_{gt})$ : old v. actual rules	0.001	-0.109*		
$\Delta \log(SP_{gt})$ : old v. new rules			0.148	
$\Delta \log(SP_{gt}^{perm}) - \Delta \log(SP_{gt}^{temp})$ : old v. new rules				-0.01

Note: \*\*\* Significant at the 1% level, \*\* significant at the 5% level, \* significant at the 10% level. Robust standard errors clustered at the occupation-year level. Agricultural and public sectors excluded.

Source: OECD analysis based on the EU-LFS.

### The impact of the severance pay reforms on hiring and separations: Evidence from the *Quadros de Pessoal*

As an additional robustness check on the findings presented in the previous section, the analysis is re-run on the *Quadros de Pessoal* (QP) data, a matched employer-employee administrative dataset. The advantages of this dataset compared to the EU-LFS are that it covers all non-public sector employees (it is a census, not a survey) and allows for the analysis to be carried out at the firm-level rather than at the more aggregate occupation-level. The disadvantages, however, are that the dataset is annual and that only the individuals working on October 31<sup>st</sup> of each year are observed. This implies that flows during the year (e.g. individuals hired and fired between October 31<sup>st</sup> of year  $t$  and October 31<sup>st</sup> of year  $t-1$ ) will not be captured. This is a problem for temporary contracts in particular. In addition, for reasons further explained below, the effect of the 1 November 2011 reform on separations cannot be estimated.

181. The randomisation works as follows. First, individuals are ordered randomly within time periods (i.e. quarter and year) and contract type groups, and are given the tenure level of the individual ranked one position below them (within the same time/contract group). In the next step, individuals are ordered by tenure within time periods, and the individual are given the contract type (temporary or permanent) of the individual ranked one position below them (within the same time period). By first assigning tenure (within contract type groups) and then only contract type, situations are avoided where, for example, individuals on temporary contracts might have very high tenure.

The outcomes that one is able to investigate using the QP data are slightly different from those in the EU-LFS.<sup>182</sup>

- Separations (i.e. the share of employees who were employed by the firm in year  $t-1$  but not in year  $t$ );
- Hiring (the share of employees who were employed by the firm in year  $t$  but not in year  $t-1$ );
- Share of hires that are permanent.

The basic model is re-defined at the firm-level:

$$Y_{jt} = \beta_0 + \beta_1 \Delta \log(SP_{jt}) + \sum_{c>1} \beta_c Z_{cjt} + \gamma_t + \delta_j + \varepsilon_{it} \quad (3)$$

Where  $Y_{jt}$  is the employment outcome for firm  $j$  at time  $t$  and  $\Delta \log(SP_{jt})$  is the average percentage difference in severance pay between the pre- and post-reform systems. As in the EU-LFS analysis, the difference between old and actual severance pay is used in the separations regressions, while the difference between old and new severance pay is used in the hiring regressions.<sup>183</sup> Just as before, the impact of the share of hiring that is permanent is analysed using the difference in severance pay reductions between permanent and temporary contracts. The regression further controls for time-varying firm characteristics,  $Z_{jt}$ , (such as the type of collective bargaining coverage<sup>184</sup> and productivity<sup>185</sup>), as well as firm and year fixed effects.

Table C4 reports the estimated coefficients on the severance pay variable,  $\beta_1$ , for each different outcome for the period 2010-2013. As before, the results can be interpreted as the percentage point change in the outcome of interest of a 1-percentage point increase in the difference in severance pay before and after the reform (or of a 1-percentage point increase in the difference in severance pay reductions between permanent and temporary for the last column). The results show that firms that experience a larger fall in the severance pay level of their employees exhibit a higher separation rate. Although significant, the value of the coefficient is relatively small and will partly reflect the higher tendency of on-the-job search found in the LFS analysis (and therefore increased job-to-job flows). The results in Table C4 further show that firms that anticipate a bigger drop in severance pay levels for their future employees have a higher hiring rate. Finally, the results indicate that the severance pay reforms may have had a positive impact on the share of permanent workers. Overall, these results are remarkably similar to the ones obtained using the LFS data.<sup>186</sup>

182. Note that, while the definition of hiring is similar to the EU-LFS definition, the separations definition is broader as it also refers to individuals moving to another job. The separations and hiring rates on the QP data are therefore more comparable to one another, and the results clearly show that the effect of the reforms on hiring is significantly larger than the effect on separations. This may be a result of grandfathering.

183. The first reform had no impact on the severance pay of existing workers. Any effect of the reform on separations would therefore only occur on individuals who are hired after the reform. However, because the QP only records individuals in employment in October of each year, anyone who joins a firm and leaves again during the year will not be captured. As such, the QP data cannot be used to estimate the effect of the 2011 reforms on separations.

184. Share of uncovered workers, share of workers covered by firm-level agreements, and share of workers covered by sector/national agreements (base category).

185. Productivity is defined as the firm's turnover divided by the number of employees.

186. Again, it is not straightforward to interpret the magnitude of these effects. Starting with separations, 14.2% of workers separate from their employer each year. At the same time, the average difference between old and

**Table C4. The impact of the severance pay reforms on hiring and separations: Evidence from the *Quadros de Pessoal***

	Employment outflows	Hiring	Share permanent hiring
$\Delta \log(SP_{gt})$ : old v. actual rules	0.043***		
$\Delta \log(SP_{gt})$ : old v. new rules		0.292***	
$\Delta \log(SP_{gt}^{perm}) - \Delta \log(SP_{gt}^{temp})$ : old v. new rules			0.624***

Note: \*\*\* Significant at the 1% level, \*\* significant at the 5% level, \* significant at the 10% level. Robust standard errors clustered at the firm level. Agricultural and public sectors excluded.

Source: OECD analysis based on the *Quadros de Pessoal*.

To test the robustness of these results, a falsification exercise similar to that run on the EU-LFS data is also run on the QP. Randomising the tenure levels and contract types of employees leads to strongly different results, with all coefficients changing sign (Table C5). As before, this strengthens the case for ascribing the effects observed in Table C4 to the severance pay reforms. Even the coefficient on hiring is now much smaller, and changes sign.

**Table C5. The impact of the severance pay reforms on hiring and separations: Falsification exercise with randomised tenure and contract type (*Quadros de Pessoal*)**

	Employment outflows	Hiring	Share permanent hiring
$\Delta \log(SP_{gt})$ : old v. actual rules	-0.037***		
$\Delta \log(SP_{gt})$ : old v. new rules		-0.054***	
$\Delta \log(SP_{gt}^{perm}) - \Delta \log(SP_{gt}^{temp})$ : old v. new rules			-0.015

Note: \*\*\* Significant at the 1% level, \*\* significant at the 5% level, \* significant at the 10% level. Robust standard errors clustered at the firm level. Agricultural and public sectors excluded.

Source: OECD analysis based on the *Quadros de Pessoal*.

The model was also run separately for small firms (fewer than 50 employees) and large ones (50 employees or more). The results, presented in Table C6, show that most of the effect of separations occurs in small firms – which suggests that these firms might be particularly constrained by high firing costs, which could impede their productivity and growth. The impact of the reform on hiring and the share of hiring that is permanent is significant in both types of firms, although the effects are larger for small ones.

actual severance pay in the QP data is 5.6%, and the results show that 1-percentage point increase in this difference results in a 0.04-percentage point increase in the separation rate. Turning to hiring, 16.2% of workers are new hires each year, while the average difference between old and new severance pay is 25.6%. The results show that a 1-percentage point increase in this difference is associated with a 0.29-percentage point increase in the hiring rate. Finally, the average share of hiring that is permanent is 46.9%, while the difference in severance pay reduction for permanent and temporary contracts is 3.4 percentage points. A 1-percentage point increase in this difference would increase the share of hiring that is permanent by 0.6 percentage points.

Table C6. The impact of the severance pay reforms on hiring and separations, by firm size (*Quadros de Pessoal*)

	Small firms (<50)			Medium and large firms (≥50)		
	Employment outflows	Hiring	Share permanent hiring	Employment outflows	Hiring	Share permanent hiring
$\Delta \log(SP_{gt})$ : old v. actual rules	0.044***			-0.073		
$\Delta \log(SP_{gt})$ : old v. new rules		0.293***			0.172***	
$\Delta \log(SP_{gt}^{perm}) - \Delta \log(SP_{gt}^{temp})$ : old v. new rules			0.658***			0.300***

Note: \*\*\* Significant at the 1% level, \*\* significant at the 5% level, \* significant at the 10% level. Robust standard errors clustered at the firm level. Agricultural and public sectors excluded.

Source: OECD analysis based on the *Quadros de Pessoal*.

Finally, the model was used to test whether the severance pay reforms affected wage growth at the firm-level. One can imagine that workers in firms most affected by the severance pay reforms would lose in bargaining power over wages as their likelihood of being fired has increased. Indeed, the results presented in Table C7 indicate that firms with a larger average gap between old and actual severance pay have lower wage growth. By contrast, the average firm-level gap between old and new severance pay has no effect on wage growth – as might be expected.

Table C7. The impact of the severance pay reforms on wage growth (*Quadros de Pessoal*)

	Hourly wage growth	Hourly wage growth
$\Delta \log(SP_{gt})$ : old v. actual rules	-0.030**	
$\Delta \log(SP_{gt})$ : old v. new rules		0.016

Note: \*\*\* Significant at the 1% level, \*\* significant at the 5% level, \* significant at the 10% level. Robust standard errors clustered at the firm level. Agricultural and public sectors excluded. Hourly wage calculated as the sum of base wages, overtime wages and other payments, divided by the sum of normal and overtime hours.

### The impact of the severance pay reforms on individual employment survival: Evidence from the European Labour Force Survey

This final section homes in on the question of whether lower severance pay results in higher job separations. It does this by exploring detailed information from the EU-LFS on the starting date of contracts to analyse differences in employment survival between employees who signed their contract just before the 1 November 2011 reforms and those who signed just after. Employees who signed a contract on or after that date would accumulate severance pay entitlements at a slower rate than those who signed their contract before that date, and also no longer have an entitlement to a minimum of three months' severance pay. As such, one would expect to see higher separation rates for workers hired after 1 November 2011 because: i) employers would be more likely to fire them; and ii) the workers themselves may be less reluctant to leave their job.

To make sure that the “treated” individuals (i.e. those who signed their contract after the reform) in the analysis are as similar as possible to the “control” individuals (i.e. those who signed their contract before the reform), a short time window around the reform date is chosen. More specifically, the sample is restricted to employees who signed their contract in the two months prior to the reform and in the two months after (i.e. it includes any contract signed over the period September to December 2011). Figure C1 shows the evolution of the number of employed people in both the control and the treatment groups. As expected, both groups reduce in size as time passes. However, Figure C1 also suggests that the gap

between the two groups of employees may have widened slightly over time and that the line for “treated” individuals is slightly steeper – which indicates that the workers hired under the new severance pay system are fired or leave their job more easily.

Figure C1. Evolution of the number of workers who signed their contract just before or just after the 1 November 2011 severance pay reform

Source: OECD analysis based on the EU-LFS.

To test this hypothesis more formally the following regression setup is used:

$$Y_{it} = \beta_0 + \beta_1 t + \sum_{c>2} \beta_c X_{cit} + \varepsilon_{it} \quad (4)$$

Where  $Y_{it}$  is a dummy variable equal to one if an employee belongs to the treatment group and zero when he/she belongs to the control group. The variable of interest,  $t$ , is a simple linear time trend, and the regression also controls for individual characteristics (age, skills, gender, contract type and region). As such, this model tests whether the share of employees who signed their contract after 1 November 2011 increases or decreases over time. The estimated coefficient ( $\beta_1 = -0.023$ ) is significant at the 1% level, suggesting that employees covered by the new severance pay system have a lower probability of survival than employees under the old system.

One can also test whether employees who signed their contract just after the reform have a higher probability of on-the-job search than those who signed their contract just before the reform. This is done by estimating the following model:

$$S_{it} = \beta_0 + \beta_1 Y_{it} + \sum_{c>2} \beta_c X_{cit} + \varepsilon_{it} \quad (5)$$

Where  $S_{it}$  equals one if an employee engages in on-the-job search (zero otherwise), and  $Y_{it}$  is, as before, a dummy variable equal to one when an employee belongs to the treatment group (zero otherwise). The other explanatory variables remain as in equation (4), and the regression is run on the same restricted sample as before (i.e. individuals who signed their contract over the period September-December 2011).

The estimated coefficient ( $\beta_1=0.045$ ) is positive and significant at the 5% level, indicating that the severance pay reforms have led to relatively higher on-the-job search for those affected by the reform.

### The impact of the severance pay reforms on individual employment survival: Evidence from social security data

The same analysis can be repeated using social security data which contain details on the employment spells of individuals with different employers, the reasons for ending an employment spell, as well as a range of personal characteristics. The time span covered by the data extends from January 2010 to September 2015. More details on the structure and content of these data can be found in Annex D.

As in the previous analysis, a difference-in-difference model is estimated to compare the outcomes of individuals who signed their contract in the two months after the reform (treatment group) to those who signed their contract in the two months before the reform (control group):

$$Y_i = \beta_0 + \beta_1 T_i + \sum_{c>0} \gamma_c X_{ci} + \sum_{c>0} \mu_c Z_{ci} + \varepsilon_{it} \quad (6)$$

Where the treatment dummy,  $T_i$ , equals one for all employment spells  $i$  of the treatment group and zero for the spells of the control group. The regression further controls for individual characteristics,  $X_{ci}$  (age, gender, region, migrant status), and firm level characteristics,  $Z_{ci}$  (sector, and size at the end date of employment). The outcome variable,  $Y_i$ , is defined as the hazard rate of employment, i.e. the probability of leaving a job, given that the individual has been employed in the job for a duration  $d$ .

Given that the dependent variable is expressed as a hazard rate, the regression is estimated using a Cox proportional hazard model. The estimated hazard ratio equals 1.082 (significant at the 5% level), implying that individuals hired in the two months after the reform are 8.2% more likely to leave employment than the individuals hired just before the reform (Table C8).

Table C8. The impact of the severance pay reforms on individual employment survival (*Social Security data*)

	All	Employer initiative	Employee initiative
$\beta_1$	1.082**	1.129***	0.919
	-0.036	-0.043	-0.069
Observations	6168	5389	2473

Note: \*\*\* Significant at the 1% level, \*\* significant at the 5% level, \* significant at the 10% level. Robust standard errors clustered at the firm level.

Source: OECD analysis based on social security data.

The data also contain information on the reason for the end of the employment spell. When the dependent variable in the model is redefined to include exits from employment that occurred on the initiative of the employer only, the estimated hazard ratio increases to 1.129 (significant at the 1% level). On the other hand, when the dependent variable covers only exits that occurred on the initiative of the employee, no significant difference is found between the treatment and control groups. These results suggest that the reason why individuals who signed their contract under the new rules are more likely to separate from their jobs is that they are more likely to get fired.

### **Concluding remarks**

Several conclusions may be drawn from the analysis presented above. First, that the reform appears to have been successful in promoting greater worker re-allocation as well as hiring, particularly among small firms. Second, that the preservation of accumulated severance pay rights for existing workers has mitigated the impact of the reform on their probability of job separation. And, third, that the same grandfathering rules have introduced some inequalities in the labour market depending on when someone signed their contract. Indeed, the analysis showed that individuals hired under the new rules were more likely to separate from their jobs (being fired) than individuals who were still hired under the old rules. These inequalities were primarily a result of the November 2011 reforms, and later reforms tried to reduce these inequalities (or at least the rate at which they would increase) by imposing a cap on the severance pay of existing workers and reducing the rate at which further severance pay entitlements would be accumulated.

## ANNEX D

**THE IMPACT OF REDUCTIONS IN UNEMPLOYMENT BENEFIT LEVELS ON FLOWS  
FROM UNEMPLOYMENT TO EMPLOYMENT: EVIDENCE FROM ADMINISTRATIVE DATA**

The reforms of the Portuguese unemployment benefit system reduced the generosity of benefits for unemployment spells starting after April 1<sup>st</sup> 2012. The reforms entailed: i) a reduction in the maximum amount of unemployment insurance (from 3 to 2.5 times the social support index<sup>187</sup>), and ii) a 10% reduction in the unemployment insurance level after six months of unemployment (i.e. a declining replacement rate). The primary goal of these reforms was to encourage recipients to look more actively for a job and reduce the length of unemployment spells. It is important to note that the reduction in the level of unemployment benefits was only a small part of the total unemployment benefit reform package, and that the biggest effect is to be expected from the reduction in the maximum duration of unemployment insurance. However, because the latter will not apply to the first spell of unemployment after the reform, it is too early to assess its impact on unemployment duration.

This annex analyses the impact of the reduction in unemployment benefit levels on the probability of moving from unemployment to employment using social security data for the period January 2010 to September 2015 (see Box D1 for more details on the data). These data contain detailed monthly information for a sample of labour market participants, such as labour market status, social security benefits and contributions, as well as a range of personal characteristics. To isolate the impact of the reduction in benefit levels from the reduction in unemployment benefit duration, only the first spells of unemployment after the reform are taken into account.<sup>188,189,190</sup>

- 
187. Since 2009, the social support index (IAS) has been equal to EUR 419.22, which implies that the maximum monthly level of unemployment insurance was lowered from EUR 1 257.66 to EUR 1 048.05.
188. In the dataset made available for the purposes of this report, only 643 unemployment spells could be identified which were covered by the new rules on maximum unemployment benefit duration. These spells represent about 1% of the total monthly observations for unemployed individuals.
189. The reforms also changed the unemployment benefit eligibility rules by lowering the threshold for access from 450 to 360 days of contributions over the past 24 months. This will have changed the composition of both the treatment and control groups. As it is impossible to identify the persons with 360 to 450 days of contributions, the results of the analysis presented in this annex might be contaminated by this increased eligibility. Therefore, a key (but not unreasonable) assumption is that these newly eligible individuals do not have a significantly different outflow probability from individuals who were already eligible under the old rules. Either way, the difference-in-differences setup used in this annex will remove this possible bias – as long as the widened eligibility affected the treatment and control groups in the same way.
190. In the same period, unemployment benefit levels for jobless households were temporarily raised by 10% (although the new maximum benefit level and the 10% reduction after six months would still apply). While these individuals would ideally be excluded from the analysis, the lack of household information in the administrative data makes it difficult to identify them.

**Box D1. Social Security data used for unemployment insurance analysis**

The impact of the unemployment benefit reforms are analysed using a 2% social security sample on all individuals registered with Social Security on December 31<sup>st</sup> 2012. For these individuals, all monthly information between January 2010 and September 2015 is matched on. The information includes:

- Personal characteristics (age, gender and country of birth);
- Information on the employer for employed individuals (firm size and sector);
- Information on remuneration (level and taxes);
- Information on unemployment benefit (start date, type of benefit and level).

On December 31<sup>st</sup> 2012, the sample consists of 61 169 individuals, of whom 11.72% are unemployed. The number of individuals decreases with time as some individuals disappear from the social security system. A total of 11 225 individuals have one or more unemployment spells starting after the reform. About 64% of them have spells longer than six months and are therefore affected by the new declining replacement rate. Only about 4.7% of individuals who become unemployed after the reform are affected by the reduction in the cap (or 534 individuals).

To test the impact of the reduction in the maximum unemployment insurance level, a difference-in-differences model is estimated which compares the difference in outcomes before and after the reform between those who were affected by the cap and those who were not:

$$Y_i = \beta R_i + \gamma T_i + \delta(R_i T_i) + \sum \mu X_i + \varepsilon_i$$

The reform dummy,  $R_i$ , equals one for all unemployment spells starting after April 2012, and zero for all spells starting before. The treatment dummy,  $T_i$ , equals one for all individuals with unemployment benefits at or above 2.5 times the social support index (i.e. for all individuals affected by the reduction in the cap).<sup>191</sup> In order to make the control group ( $T_i=0$ ) as comparable as possible to the treatment group, only those people with unemployment benefits just below the maximum are selected (i.e. with benefits between 90% and 100% of the new cap).<sup>192</sup> The coefficient on the interaction term,  $\delta$ , measures the impact of the reform. It shows whether the difference between the pre- and post- reform outcomes of the treatment group is different from that for the control group. The outcome variable,  $Y_i$ , is defined as the hazard rate (or exit rate) from unemployment, i.e. the probability of moving from unemployment to employment conditional on having been unemployed for a duration  $d$ . The regression further controls for a set of personal characteristics,  $X_i$  (migrant status, age, gender, region and maximum unemployment benefit duration)<sup>193,194</sup>

A similar regression setup is used to test the impact of the 10% reduction in unemployment benefit levels after six months of unemployment. This time, however, the treatment and control groups are constructed on the basis of when the individual became unemployed. To be more precise, the impact of the reform is estimated by comparing individuals who became unemployed just before the reform to those who became unemployed just after, and the regression model becomes:

$$Y_i = \beta R_i + \sum \mu X_i + \varepsilon_i$$

191. The reduction of the maximum amount by 10% after six months (for spells starting after the reform) is taken into account in the definition of the treatment and control groups.

192. Expanding this group to those with benefit levels between 80% and 100% of the cap does not affect the results obtained.

193. All personal characteristics are entered into the regression as dummy variables (two migrant statuses, five age groups, two genders, seven regions, three benefits duration levels).

194. In a robustness check using discrete duration models monthly dummies are added to control for possible seasonality in the hazard rate. Their inclusion does not, however, alter the result.

Where the reform dummy,  $R_i$ , equals one for all individuals whose employment spell started in the two months following the reform (April and May 2012) and zero for the individuals with an unemployment spell starting in the two months before the reform (February and March 2012). To make the treatment and control groups more comparable, they are further limited to having a level of initial unemployment benefits (before the 10% reduction) of between EUR 15 and EUR 34 per day. These levels are chosen as to not include individuals subject to the minimum or maximum benefit level, given that the minimum level hides large difference in previous wage levels and that the maximum was subject to an additional reform. The outcome variable,  $Y_i$ , and the control variables,  $X_i$ , remain as before.

Given that the outcome variable in both models is defined as a hazard rate, the regressions are estimated using a Cox proportional hazard model.<sup>195</sup> Table D1 shows the hazard ratios for the variables of interest for both regressions, as well as the number of unemployment spells per person.<sup>196</sup> The hazard ratio for the maximum level regression is larger than one, which implies that the probability of exiting to employment has increased more after the reform for the treatment group than for the control group. Similarly, the estimated hazard ratio for the 10% reduction model is larger than one, which suggests that the individuals who became unemployed just after the reform have a higher probability of moving to employment than the individuals who became unemployed just before the reform. However, neither of the coefficients are significantly different from one, meaning that no definite conclusions can be drawn about the effect of the reform.<sup>197</sup>

**Table D1. The impact of unemployment benefit level reductions on unemployment outflows: Regression results**

	Maximum level	10% reduction
$R_i T_i$	1.244 (0.215)	
$R_t$		1.115 (0.112)
Number of spells	1385	702

Note: Robust standard errors displayed in parentheses.

Source: OECD analysis based on social security data.

To test the robustness of these results, the models are re-estimated using control groups obtained by propensity score matching. This ensures an even greater degree of comparability between the treatment and control groups. More specifically, each individual from the treatment group is matched to a non-treated individual with similar observable characteristics (based on age, gender, region, migrant status and maximum unemployment benefit duration).<sup>198</sup> For the first model (maximum benefit level), the new

195. A critical assumption of this Cox model is that the difference between the hazard rates of two groups is independent of the unemployment duration. While this assumption is unlikely to be violated in the maximum level regressions, it might be problematic for the 10% reduction given that the difference between the two groups only starts after six months of benefits. However, allowing for a different coefficient before and after six months of unemployment duration did not significantly improve the model. This does not change when anticipation is taken into account (i.e. setting the threshold at four or five months of unemployment duration).
196. The number of spells is very close to the number of individuals, given that there are only few individuals with multiple unemployment spells.
197. The impact of the 10% reduction in benefit level after six months could be greater for individuals with greater liquidity constraints. To test for this, the analysis was re-run separately on two different groups with varying levels of unemployment benefit (one with unemployment benefit ranging between EUR 15 and EUR 20 per day, the other with benefit levels between EUR 20 and EUR 34 per day). The reform did not have a statistically significant impact on the flows from unemployment to employment for either group.
198. Individuals at the minimum or maximum benefit level are excluded from the treatment and control groups.

control group consists of the nearest neighbours of the treated individuals, both before and after the reform.<sup>199</sup> For the second model, all individuals starting their unemployment spell in the two months after the reform are matched to their nearest neighbour in the group of individuals who became unemployed in the two months before the reform.<sup>200,201</sup> Using these new control groups, the same duration models as above are estimated, but standard errors are clustered at the match level. The results in Table D2 confirm the earlier estimates, with both hazard ratios remaining insignificantly different from one. This could be due to small sample sizes, and future research should use larger extracts from the social security data to verify the results obtained here.<sup>202</sup>

**Table D2. The impact of unemployment benefit level reductions on unemployment outflows: Regression results using propensity score matching**

	Maximum level	10% reduction
$R_t \bar{T}_i$	1.071 (0.168)	
$R_t$		1.145 (0.164)
Number of spells	1435	400

Note: Robust standard errors clustered at match level displayed in parenthesis.

Source: OECD analysis based on social security data.

While this preliminary assessment could not detect any significant effect of the unemployment benefit level reforms on unemployment outflows, the benefit reductions will still have had an impact on the government budget. An estimated 4.8% of beneficiaries were affected by the reduction in the cap over the period April 2012 to September 2015, with an average saving in UB of almost EUR 185 per beneficiary per month – resulting in a total saving of around EUR 70 million over the entire period. The saving associated with the 10% reduction was even greater: EUR 200 million over the period April 2012 to September 2015.<sup>203</sup> It is important to note that these estimates only represent a rough approximation of the actual savings from the reforms, as the calculations are based on a 2% random sample of the Social Security records. The calculations therefore assume that the sample is representative of the wider population.

199. The group from which the nearest neighbours for the maximum level treatment group are selected is restricted to individuals with unemployment benefits between 80% and 100% of the maximum benefit level.
200. Both for the maximum level control group, as for the 10% reduction control group, propensity score matching is done using a k-nearest neighbour matching method with  $k = 2$ .
201. While limiting the treatment group to individuals with employment benefit levels between EUR 20 to EUR 34 does not alter the results, the estimated coefficient for the treatment group limited to benefits between EUR 15 and EUR 20 becomes significantly larger than 1 (indicating that the reform may have had an effect on exits from unemployment to unemployment), albeit only at the 10% significance level.
202. As an additional robustness check the models have been re-estimated in a discrete setup (i.e. transforming the data from spells to monthly observations), using both a standard logistic estimator and a proportional hazard model. As expected, the estimated coefficients are very close to the ones reported in tables D1 and D2.
203. Whereas unemployment benefits without the 10% reduction can easily be identified in the social security data from the actual unemployment benefit level, the benefit level in the absence of the new lower cap is more difficult to estimate. Based on the observed wage in the previous job, it is nevertheless possible to calculate approximately what the benefit would have been in the absence of the new cap. Comparing this level to the current cap provides an estimate of the reduction caused by lowering the cap. To estimate an upper bound on the savings from this reform, one can alternatively assume that the saving for each individual affected is simply the difference between the old and the new cap. This leads to a total saving of EUR 79 million.

## ANNEX E

**THE IMPACT OF ACTIVE LABOUR MARKET PROGRAMMES ON EMPLOYMENT  
OUTCOMES: EVIDENCE FROM ADMINISTRATIVE DATA**

The Portuguese public employment service (PES) provides a range of active labour market programmes (ALMPs), such as internships, hiring subsidies and training programmes. As documented in Chapter 1, some of these programmes have been revised substantially over the last few years, and new programmes have been introduced.

In this annex, the impact of a set of ALMPs on individual employment outcomes is analysed using administrative data from the Portuguese PES for the period 2010-2015. These data contain information on the programmes that each unemployed individual registered at the PES participated in. Additionally, registration dates as well as dates and reasons for exit are documented, together with a set of personal characteristics (Box E1).

**Box E1. Public Employment Service data used for the evaluation of ALMPs**

The extract of administrative data from the Portuguese PES used for the present analysis contains information for all individuals who were registered with the PES on December 31st 2011 as well as for all new entrants to the PES until the end of 2014. The dataset therefore contains all registered unemployed over the period 2012-2014, and information for these individuals pre-2012 and post-2014. In total, the dataset contains information on 1 846 393 unemployed individuals.

Information is available on date of registration at the PES, interventions by the PES (e.g. ALMPs), placements, annulments and a range of personal characteristics. An individual leaves the dataset following placement by the PES (12% of exits) or annulment (88%). In total, 44 different reasons for annulment are present in the dataset. These consist of five broad categories: self-placement (27%), refusal of activation measures (26%), absence for controls (30%), leaving the labour market (6%), dropout from intervention (2%), and other (6%).

The PES data contain information on 220 different interventions, varying strongly in number of participants. The most common interventions are “placement interview”, “personal development plan”, and “active job search” – i.e. standard PES services. The programmes evaluated in this report cover around 7% of all registered interventions and 45% of all ALMPs (71% excluding *formação contínua*). Table A shows that Vida Ativa (a short-duration training programme) is by far the largest among the evaluated programmes, while the reported number of participants in the hiring subsidy programme is relatively low. The average age, schooling level and unemployment duration at the start of participation (proxied by the number of months since registration) reflect the eligibility criteria of the different programmes (see Annex A).

**Table A. Characteristics of ALMP participants**

	Number of participants	Average age	Average years of schooling	Average months registered with PES
Subsidised internships	116 834	26.1	14.4	7.3
Hiring subsidies	15 826	33.9	11	13.5
Vida Ativa	564 599	40.2	9.6	12.9
Socially useful work	200 388	42.2	8	11.1

*Note:* Subsidised internships include *Passaportes emprego*, *Estágios profissionais*, *Estágios emprego*; hiring subsidies includes *Estímulo 2012*, *Incentivo à contratação*; socially useful work includes *Contrato emprego-inserção*, *Contrato emprego-inserção+*.

*Source:* OECD analysis based on PES administrative data.

The goal of this analysis is to see whether individuals who participated in an activation programme had a higher probability of being employed, compared to similar individuals who did not participate in the same activation programmes. More specifically, individuals starting a programme at time  $t$  are compared to individuals unemployed at time  $t$ , but who never participated in that programme. The probability of employment for these two types of individuals is compared at times  $t+6$ ,  $t+12$ ,  $t+18$  and  $t+24$ .

To make the control group (i.e. the individuals who did not participate in a specific ALMP) as comparable as possible to the treatment group (i.e. the participants), propensity score matching is used.<sup>204,205</sup> Everyone from the treatment group is matched to a similar person in the control group based on age, gender, marital status, whether or not the individual has children, years of schooling, date of registration with the PES, and whether or not the individual has already been employed. This matching process is done separately for each month in which the ALMPs are started.<sup>206</sup> As it is possible that individuals participate in multiple ALMPs, the analysis is repeated for a treatment group of individuals who only participated in the ALMP of interest and a control group of individuals who did not participate in any ALMP at all.<sup>207</sup>

Given that the matching process is limited to observable characteristics of the individuals, there might still be a significant difference between the treatment and control group in terms of unobservable characteristics, such as motivation and innate ability. These unobservable characteristics might, in turn, affect the outcome of interest and therefore bias the estimates of the impact of the programme. However, given the lack of natural experiment, it is impossible to take these unobserved characteristics into account. That being said, the wide range of observed characteristics included in the matching process should reduce the extent of such bias.

The focus of the analysis is on four different types of ALMPs that are all substantial in terms of number of participants, and were introduced or reformed during the crisis period:

- Subsidised internships (*Passaportes emprego, Estágios profissionais, Estágios emprego*)
- Hiring subsidies (*Estímulo 2012, Incentivo à contratação*)<sup>208</sup>
- Short-duration training programmes (*Vida Ativa*)
- Socially useful work (*Contrato emprego-inserção, Contrato emprego-inserção+*)

More details on these ALMPS can be found in Annex A.

---

204. Propensity score matching is done on a one-to-one basis without replacements

205. Another option would have been to run a basic OLS regression of the outcome variable (employment) on a treatment dummy (1 if treated, 0 if control) and individual characteristics. The advantages of PSM are that it is non-parametric, and therefore more flexible, and that it only looks at comparable observations (common support).

206. Individuals starting an internship at time  $t$  can only be matched to individuals who were unemployed at time  $t$ . When an individual is included in the control group for the treatment group with starting date  $t$ , he or she is excluded from potential matching with treatment groups with starting dates  $t' > t$ .

207. The restriction does not apply to some very standard PES interventions, such as information sessions or the personal development plans (*Sessão de informação colectiva, Plano Pessoal de Emprego*)

208. The PES data do not allow the identification of *Estímulo 2013* and *Apoio a contratação via reembolso da TSU* participants.

Table E1 shows the probability of employment after 6, 12, 18 and 24 months for the treatment and control groups, and for the four different types of ALMPs. An individual is considered to be employed when he or she has permanently left the PES database and when the reason for exiting is either placement by the PES or self-placement. Unemployment is defined as being registered in the PES database. The main drawback of these definitions is that they ignore individuals who left the PES dataset for other reasons than (self-)placement. This is because the PES data do not allow the identification of the labour market status of these individuals, and they can therefore not be classified as either employed or unemployed.

Individuals participating in a subsidised internship programme have a higher probability of being employed than comparable individuals not participating, except six months after the start of the programme (Panel A). This latter finding is not surprising, given that the majority of the treated individuals are by definition still unemployed after six months since internship programmes normally last for more than six months. The fact that the employment probabilities of the treatment group after finishing the internship are higher than the probabilities of the control group suggests that participating in an internship has a positive impact on the probability of finding a job (and staying employed) – assuming that there was no selection into the programme based on observable characteristics. This is consistent with the fact that many internships are transformed into normal contracts at the end of the internship programme (42% of all internships starting in 2012-2014).

An even more pronounced difference in employment probabilities is found for the hiring subsidies (Panel B). Because individuals participating in a subsidised job are registered as employed and *Estímulo 2012* subsidies lasted for six months, the employment probability of the treatment group after six months is very high by definition. However, even after ending the subsidised job, the employment probabilities for the treatment group remain substantially higher than for the control group. After two years, those who benefited from a hiring subsidy are still 70% more likely to be in employment than similar individuals who did not.

By contrast, *Vida Ativa* appears to have very little impact on the employment outcomes of participants (Panel C). It is not clear why this is but possibilities include the broad nature of the programme (it covers modular training as well as validation of existing skills), the fact that the intensity of the programme can differ strongly across participants, and also that the programme is modular so that the full effect of the programme may not be captured in the present analysis, but only part of it.<sup>209</sup>

Finally, the employment probabilities of individuals participating in a socially useful work programme are slightly higher after 12 and 18 months than those of similar individuals in the control group. However, there does not seem to be a long-run effect of these programmes, as the employment probabilities of the treatment and control groups are almost equal after 24 months. Compared to the individuals participating in the subsidised internships from Panel A, the individuals participating in a socially useful work programme have a much lower probability of being offered a job by the employer where their socially useful internship was done (only 3.2% of all individuals starting such a programme over the period 2012-2014).

---

209. The PES data do not provide detailed information on the exact content of the *Vida Ativa* measures for each individual. The intensity of the programme can, however, be proxied by its duration. When excluding participants who participated in *Vida Ativa* for less than five days, the difference in employment probabilities between the treatment and control groups becomes bigger, but remains limited to 4 percentage points after 24 months.

**ABSTRACT**

Latin American countries are the only Western countries that are poor and that aren't gaining ground on the United States. This paper evaluates why Latin America has not replicated Western economic success. We find that this failure is primarily due to TFP differences. Latin America's TFP gap is not plausibly accounted for by human capital differences, but rather reflects inefficient production. We argue that competitive barriers are a promising channel for understanding low Latin TFP. We document that Latin America has many more international and domestic competitive barriers than do Western and successful East Asian countries. We also document a number of microeconomic cases in Latin America in which large reductions in competitive barriers increase productivity to Western levels.

## 1. Introduction

Various short-run crises—exchange rate crises, debt crises, inflation crises, balance-of-payment crises, financial crises—have dominated recent macroeconomic research about Latin America. This literature focuses on the causes of these crises and their short-run impact on macroeconomic fluctuations, taking the trend paths of macroeconomic variables as exogenous. Systematic analyses of Latin American macroeconomic trends have received much less attention.<sup>1</sup> This paper presents a comparative analysis of Latin American macroeconomic trends over the last 50 years using a neoclassical growth framework.

We first compare long-run Latin American macroeconomic performance to that in a number of other countries to provide a benchmark for what Latin America could have reasonably achieved. We make two sets of comparisons. We compare Latin America's long-run performance to that in a peer group of other Western market economies—the other countries with a large fraction of citizens of Western European descent. This comparison shows that *all* Western countries—including those with initial income levels reasonably similar to those in Latin America in 1950—have made substantial progress in catching up to the United States. In sharp contrast, no Latin American country has made any significant progress in catching up to the United States. We also compare Latin America to a number of East Asian countries that had initial income levels equal to or lower than those in Latin America in 1950. These countries also have had substantial catch-up. These comparisons motivate the question we address: Why can't Latin America catch up to its Western peer countries and to the successful East Asian countries?

To gain a better understanding of Latin America's stagnation, we decompose per capita GDP for Latin America and the other countries into two components: output per worker and employment as a fraction of the adult population. This comparison shows that Latin America's stagnation is primarily the consequence of a labor productivity failure; Latin American labor productivity has failed to gain any ground on U.S. labor productivity over the last 50 years. In contrast, the development successes of all the other countries are largely the consequence of labor productivity successes; labor productivity in all of these other countries is catching up to U.S. labor productivity. Understanding Latin America's relative stagnation

---

<sup>1</sup>Elias (1992) is an exception.

requires understanding its relative productivity stagnation.

We report two main findings. First, we find that stagnant relative total factor productivity (TFP) is the key determinant of Latin America's relative income and labor productivity stagnation. Second, we find that a human capital difference is not the key determinant of Latin America's TFP gap, but that barriers to competition are a promising factor. We draw this latter conclusion because both the breadth and depth of Latin American competitive barriers far exceed those in the Western countries or in East Asia, and because there are a number of microeconomic cases in Latin America in which large changes in the size of competitive barriers are systematically followed by large productivity changes. In particular, big increases in barriers to competition are followed by large productivity decreases, and big decreases in these barriers are followed by large productivity increases.

The paper is organized as follows. Section 2 develops a neoclassical model for organizing our investigation. Section 3 compares Latin America's output to that in Europe and East Asia. Section 4 decomposes Latin American output into its labor productivity and employment components and investigates the source of low Latin American labor productivity. Section 5 quantifies how much of Latin America's TFP gap can be accounted for by human capital. Section 6 discusses theoretical models in which competitive barriers lead to low productivity. Section 7 documents that Latin America has erected a number of domestic and international barriers to competition that significantly exceed competitive barriers in either Europe or East Asia. Section 8 presents a number of empirical microeconomic cases that document how government policies that limit competition have significantly reduced TFP in some Latin American countries. Section 9 concludes.

## 2. A Neoclassical Framework

We use the neoclassical growth model to guide our analysis. In this closed economy model, there is a representative household for country  $i$  with the following objective function:

$$\max E_0 \sum \beta_i^t \{u_i(C_{it}, L_{it})\},$$

where  $\beta_i$  is the discount factor for country  $i$ ,  $u_i$  is the preference for consumption and labor in country  $i$  in period  $t$ ,  $C_{it}$  is consumption, and  $L_{it}$  is labor supply. The population is denoted

by  $N_{it}$  and is normalized to be one in period 0. The population of country  $i$  grows at the constant rate of  $n_i$  :

$$N_{it} = (1 + n_i)^t.$$

A constant returns to scale Cobb-Douglas technology produces output for consumption and investment:

$$A_{it}K_{it}^\theta L_{it}^{1-\theta} \geq C_{it} + X_{it},$$

where  $A_{it}$  is TFP,  $K_{it}$  is capital services,  $L_{it}$  is labor services, and  $X_{it}$  is investment. The law of motion for capital is given by

$$K_{it+1} = X_{it} + (1 - \delta)K_{it}, \quad K_{i0} \text{ given.}$$

The process  $A_{it}$  is the product of two components, as in Parente and Prescott (2004):

$$A_{it} = \eta_{it}A_t, \quad 0 < \eta_{it} \leq 1,$$

where  $A_t$  is the world technology frontier and  $\eta_{it}$  is the relative efficiency of country  $i$  in using that technology. For our empirical analysis, we will assume that U.S. TFP is a reasonable proxy for the world technology frontier, which implies that  $\eta_{US} = 1$ . For our purposes, the process generating  $A_t$  is unimportant, though at certain points we will find it convenient to assume that it grows at the constant rate  $\gamma$ . The relative efficiency term  $\eta$  is a key component in our model. For present purposes, we treat this as a parameter.

This simple model generates long-run income differences between countries through two channels: (1) through the relative efficiency term  $\eta$  and (2) through differences in the relative supplies of capital and labor, which in our model are governed by country-specific preference differences. Note that any factor that affects income in the long-run—such as tax distortions—will manifest itself as a change in either one or both of these two channels.<sup>2</sup> We

---

<sup>2</sup>For example, capital income tax differences would show up as a difference in the relative discount factor,

will first use this model to gauge how important these two channels are for understanding Latin American macroeconomic development. We will then evaluate the deeper factors that lie behind the differences in efficiency or relative employment of the factors of production in Latin America.

### 3. Latin America's Persistent Economic Stagnation

This section examines Latin America's long-run macroeconomic performance, which we measure as per capita income relative to that of the world frontier (U.S. per capita income). Interpreting the income gap between Latin America and the United States requires a *benchmark* that lets us assess how large of a gap should be expected today, and how much this gap should have changed over the last 50 years.

We construct an empirical benchmark for assessing Latin American development. We do this by forming a set of peer group countries for Latin America and by measuring the income gaps in the peer group relative to the United States over the last 50 years. We treat the income gaps between the peer group and the United States as a benchmark for interpreting the income gap between Latin America and the United States.

The peer group is the countries that we assume are similar to Latin America in their ability to adopt and learn new technologies and that are similar in their preferences for market goods. In terms of the language of our model, this means we are looking for countries that have the ability to achieve similar levels of  $\eta_i$  and that have similar  $\beta_i$  and  $u_i(C_i, L_i)$ . Because Latin America is significantly populated by individuals of European descent, we define the peer group to be the other Western countries: the Western/Northern/Southern European nations, plus the countries that have been significantly populated by Europeans and in which European religion, language, and culture have been dominantly established.<sup>3</sup>

Our organizing view for this peer group is that since the Europeans who populated these regions established Western religion, language, and culture, then it should have been feasible for them to replicate the successful economies of the West. More specifically, this

---

and labor income tax differences would show up as a difference in the relative preference for leisure.

<sup>3</sup>The peer group is Belgium, Canada, the United Kingdom, Spain, Portugal, Greece, France, Denmark, Sweden, Norway, Finland, Netherlands, Italy, Australia, Austria, Switzerland, New Zealand, Ireland, Iceland, Greenland, Germany, and the United States.

commonality leads us to assume that Latin America and the other Western countries should have the same innate ability to learn and adopt successful Western technologies, and that with similar cultures, they should have similar preferences for market goods.

Our assumption that similar cultures have similar preferences for market goods follows in part from Cole, Mailath, and Postlewaite (1992), who established a formal connection between culture and preference orderings. In their framework, cultural differences between countries can lead to differences in nonmarket rewards for market activities. There are self-enforcing social arrangements in their model in which nonmarket goods are allocated on the basis of wealth or income. This implies reduced form differences in preference orderings over market goods according to cultural differences and suggests a presumption that countries with similar cultures will have similar preferences for market goods.

By comparing Latin America to these peer countries, we will interpret income differences between Latin America and the peer group as idiosyncratic Latin American choices that differentially affect either the efficiency of production or the employment of the factors of production or both. We will use the term “policy choices” to broadly refer to these idiosyncratic Latin American effects.

Table 1 shows ethnic, language, and religion characteristics for Latin America’s population.<sup>4</sup> The table shows that Latin America is a Western region by these characteristics—Latin America experienced substantial European immigration and widely adopted European languages and religion. Regarding culture, a number of scholars argue that Western culture has had a substantial impact on Latin America and, in some cases, nearly wiped out native cultures. (See Hoogvelt 2001 and the references therein.)

Figure 1 shows per capita income for Latin America and the other Western countries. Income is measured as a percentage of U.S. real GDP per capita (Maddison 2001). The figure shows that the Latin American countries are the poorest Western countries. In particular, note that Western European emigrants were able to transform the regions that became Canada, the United States, Australia, and New Zealand into rich countries. In contrast, Latin America was unable to replicate this Western success. The average Latin American

---

<sup>4</sup>We include the major Latin American countries: Argentina, Bolivia, Brazil, Chile, Colombia, Costa Rica, Ecuador, Paraguay, Peru, Mexico, and Uruguay.

income is just 22 percent of U.S. income, compared to an average of 69 percent for the other Western countries.

We next assess how these relative income gaps have either narrowed or widened over time. Figure 2 shows per capita income between 1950 and 2000 for the population-weighted average of the Latin American countries and for the population-weighted average of the other Western countries that had similar income levels to Latin America in 1950. The figure shows that all the other poor Western countries have had significant catch-up over the last 50 years. The average European country in this group increased from 40 percent of U.S. income in 1950 to 67 percent in 2000. In contrast, Latin America lost ground, falling from 28 percent of the U.S. level in 1950 to 22 percent in 2000.

The figure also shows relative per capita income for some East Asian countries with initial income levels similar to or below the Latin American level in 1950. The data show that economic success can also be achieved by non-Western countries, and that Latin America is also significantly underperforming this group. The population-weighted average Asian country increased from 16 percent of U.S. income in 1950 to 57 percent in 2000. Latin America's underperformance relative to Asia is significant, because Latin America—as a Western country—should have had an advantage over Asia in copying and adopting the successful Western technologies and practices that made the West rich.<sup>5</sup>

Table 2 shows the average relative incomes for these three groups, and Figures 3–5 show relative incomes for each of the individual countries in the three groups over the 1950–2000 period. Figure 5 shows that not a single Latin American country has had any significant catch-up. The Latin American income gaps are just as wide, and for some countries wider, today as they were in 1950.

Perhaps the most striking feature of these data is the constancy of Latin America's relative stagnation. This “relative gap” measure of Latin American macroeconomic performance paints a different picture than that suggested by the more commonly used measure of GDP growth. In particular, the two measures tell a different story about post-1950 Latin

---

<sup>5</sup>We chose those European and East Asian countries that had 60 percent or less of the U.S. per capita income level and increased their relative positions by at least 10 percentage points by 2001. The European countries are Austria, Belgium, Finland, France, Germany, Greece, Ireland, Italy, Norway, Portugal, and Spain. The Asian countries are Hong Kong, Japan, Korea, Malaysia, Singapore, Taiwan, and Thailand.

American performance. Latin America did have higher growth before 1980 than after. However, according to our preferred relative gap measure, there is no significant Latin American catch-up during the pre-debt crisis period (1950–80), because the U.S. economy grew faster during the earlier period as well. Output was 28 percent of the U.S. level in 1950 and 30 percent in 1980. There was, however, substantial catch-up in the other regions. The European countries rose from 40 percent of U.S. per capita income to 70 percent of U.S. per capita income, and the Asian countries rose from 16 percent of U.S. per capita income to 46 percent of U.S. per capita income over the 1950–79 period. Thus, while Latin America was treading water in the 1950s, 1960s, and 1970s relative to the United States, the rest of these countries were moving rapidly ahead.<sup>6</sup>

These data show that Latin America’s long-standing stagnation is not the consequence of adverse shocks occurring in the post-debt crisis period. How long have these stagnation factors been in place? Maddison’s (2001) data suggest they may have persisted over the last century. Table 3 shows relative Latin American income in 1900, 1950, 1980, and 2001. These data show that Latin America’s stagnation has been the norm for the last 100 years. Latin American per capita income was 29 percent in 1900, almost exactly where it was in 1950 and slightly above where it was in 2001.<sup>7</sup> For the 10 countries that we have data for over this earlier period, per-adult income in 5 of these countries has remained roughly unchanged relative to the United States. Argentina and Chile lost substantial ground relative to the United States during this period. Argentinian income fell from 67 percent of the U.S. level in 1900 to 52 percent by 1950, and Chilean income fell from 48 percent to 40 percent of the U.S. level by 1950. Venezuela was the only country that gained ground, rising from 20 percent of the U.S. level in 1900 to 78 percent by 1950. This impressive gain (which was in part due to Venezuela’s oil exports), however, was largely lost after 1950, as Venezuela returned to 30 percent of U.S. income by 2001.

It is also possible to make even longer-run relative income comparisons, though mea-

---

<sup>6</sup>This pre-debt crisis stagnation also emerges in 11 of the 13 individual Latin American countries (except Mexico and Brazil). Hopenhayn and Neumeyer (2004) have recently argued that stagnation and then collapse more accurately describes the last 50 years for Latin America.

<sup>7</sup>We have data back to 1900 for all of our Latin American countries except Costa Rica, Boliva, and Paraguay, and these countries are small enough not to have substantially affected this average.

surement issues become more problematic. These data suggest an even longer period of stagnation or decline. Specifically, Sokoloff and Engerman (2000) estimate that Argentina was richer than the United States in 1800 and that Brazil, Chile, Mexico, and Peru had smaller relative income gaps in 1800 than they do today.

Latin America's relative stagnation is particularly puzzling when compared to the two other major stagnant regions—Africa and the Middle East. Like Latin America, neither of these two regions has gained ground on the United States in the last 50 years, but Africa and the Middle East are plagued by large, idiosyncratic development impediments, including AIDS (Africa), substantial civil conflict, ethnic cleansing, and repressive, nondemocratic institutions. Latin America has not been affected by these problems nearly as much as either Africa or the Middle East. Viewed in this light, Latin America is perhaps the most puzzling regional development failure of the last 50 years.<sup>8</sup>

#### 4. TFP Is the Cause of Latin America's Stagnation

We evaluate Latin America's stagnant relative income by decomposing output per adult ( $Y/N$ ) into two components: output per worker ( $Y/L$ ) and the number of workers relative to the adult population ( $L/N$ ):

$$\frac{Y}{N} = \frac{Y}{L} \frac{L}{N}.$$

This decomposition shows that Latin America's stagnation is the consequence of either low worker efficiency ( $Y/L$ ) or low employment ( $L/N$ ). Table 4 shows that employment is not the key factor accounting for Latin America's stagnation. Latin America's employment rate is on average about 70 percent as high as in Europe and in the United States. This gap is significant, but is clearly not large enough to account for the fact that Latin America has only 25 percent of U.S. per capita income.<sup>9</sup>

This finding implies that productivity is the key factor. Figure 6 establishes this by showing labor productivity for Latin America, Europe, and Asia between 1950 and 2000.

---

<sup>8</sup>Barro's (1991) finding that a Latin American dummy variable in his growth regression exerts a larger negative effect than the African dummy variable is consistent with this view.

<sup>9</sup>Interesting studies of this labor supply gap include Heckman and Pages (2003) and Caballero et al. (2004).

These productivity data are measured relative to the U.S. productivity level. These data show that the primary reason behind the output catch-up in Europe and Asia is that labor productivity in these countries is catching up to the U.S. level. The figure also shows that Latin America's stagnation is because of stagnant productivity. In particular, Latin American productivity was 33 percent of the U.S. level in 1950 and 32 percent of the U.S. level in 1998. In contrast, European productivity rose from 39 percent of the U.S. level to 79 percent of the U.S. level in 1998, and Asian productivity rose from 15 percent of the U.S. level to 54 percent of the U.S. level over the same period.

This section investigates Latin American labor productivity by decomposing productivity into two pieces: physical capital per worker and the efficiency of production (TFP). We then evaluate the relative contribution of each of these components to Latin America's labor productivity gap. The relative size of these two factors is important for understanding why Latin American productivity is not catching up. If TFP is the dominant factor, then we should be formulating explanations for why production efficiency is so much lower in Latin America than in the United States. Alternatively, if low capital per worker is the dominant factor, then we should be formulating explanations for why capital formation is so much lower in Latin America than in the United States.

The Cobb-Douglas production function in our model yields the following expression for labor productivity:

$$(1) \quad \frac{Y_{it}}{L_{it}} = A_{it} \left( \frac{K_{it}}{L_{it}} \right)^\theta .$$

Latin America's relative labor productivity gap is thus determined by its TFP gap and its capital-labor ratio gap:

$$\frac{\left( \frac{Y_t}{L_t} \right)^{Latin}}{\left( \frac{Y_t}{L_t} \right)^{US}} = \frac{\left[ \eta_t A_t \left( \frac{K_t}{L_t} \right)^\theta \right]^{Latin}}{\left[ A_t \left( \frac{K_t}{L_t} \right)^\theta \right]^{US}} = \frac{1}{3} .$$

Before proceeding, note that TFP contributes to changes in labor productivity in two ways. There is a direct effect, as TFP shifts the production function, and an indirect effect,

as TFP impacts the capital-labor ratio. This latter impact is observed in the Euler equation that governs capital accumulation. Rewriting this equation yields

$$\frac{K_{t+1}}{L_{t+1}} = \left( \frac{(1 + \gamma)(1 + n)/\beta \frac{u_{ct}}{u_{ct+1}} - (1 - \delta)}{\theta \eta A} \right)^{1/(\theta-1)},$$

where  $\gamma$  is the growth rate of frontier TFP,  $n$  is the population growth rate,  $u_c$  is the marginal utility of detrended consumption,  $\beta$  is the household's discount factor,  $\eta A$  is TFP, and  $\delta$  is the depreciation rate of capital. This shows that the capital-labor ratio is affected by the level of TFP, by parameter values, and by transitional dynamics associated with changes in the intertemporal marginal rate of substitution. The productivity decomposition between TFP and capital per worker thus needs to account for both the direct and the indirect contribution of TFP to labor productivity.

The first step in this decomposition is obtaining capital stock measures. Table 5 shows decade averages of the capital-to-output ratio for Europe, Asia, and Latin America relative to the United States. The data are from Nehru and Dhareshwar (1993). The table shows that Latin America's ratio has been roughly within 10 percent of the U.S. ratio since the 1960s. Asia is the only group in which there is evidence of a significant capital deficiency during the last 50 years. Asia's capital-output ratio was only 36 percent of the U.S. level in the 1950s, but increased to the U.S. level by the 1980s. These data suggest that a capital shortfall is not the major factor retarding Latin America's productivity.

We supplement these capital stock data with capital investment flow data from the World Bank (2002). These investment data also indicate that Latin America has about the same capital-output ratio as the United States. Table 6 shows the ratio of investment to GDP for the United States, Europe, and Latin America. The key point is that Latin America's investment share has been roughly constant and is also about the same as the U.S. investment share. The near constancy of these investment shares also suggests that both the United States and Latin America have been near their respective steady state growth paths. This steady state evidence implies the following relationship between investment and

the capital stock for both Latin America and the United States:

$$\left(\frac{I}{Y}\right) \approx (\delta + n + \gamma) \left(\frac{K}{Y}\right).$$

Moreover, since the investment shares are about the same for both regions, we have

$$(\delta + n + \gamma)^{Latin} \left(\frac{K}{Y}\right)^{Latin} \approx (\delta + n + \gamma)^{US} \left(\frac{K}{Y}\right)^{US}.$$

This expression implies that the capital-output ratios are about the same in the two regions, because the sum of these parameter values is about the same for the two regions. This is because the growth rate of frontier productivity is the same. The population growth rate in Latin America is slightly higher than in the United States, but Latin America probably has a slightly lower depreciation rate, since the fraction of its capital stock accounted for by rapidly depreciating information processing equipment is probably smaller than in the United States.<sup>10</sup>

The three observations that (1) Latin America and the United States have roughly the same capital-output ratios, (2) Latin American output per capita is about one-fourth of U.S. output per capita, and (3) Latin American employment per capita is about three-fourths of U.S. employment per capita mean that the Latin American capital-labor ratio is one-third of the U.S. level. This implies that Latin American TFP is about one-half of the U.S. TFP level.

We estimate that Latin America's 50 percent TFP gap accounts for virtually all of its labor productivity gap. The 50 percent TFP gap directly accounts for about two-thirds of the labor productivity gap, and we will next show that the indirect effect of TFP accounts for about the remaining one-third.

To see this, we make use of the fact that Latin America has been near its steady state growth path over the last 50 years, along with our assumption that the values for the parameters  $\gamma$ ,  $n$ ,  $\delta$ ,  $\theta$ , and  $\beta$  are the same in the two regions.<sup>11</sup> The steady state Euler equation

---

<sup>10</sup>The Latin American population growth rate is about 1.7 percent per year, compared to the U.S. population growth rate. See [http://www.overpopulation.com/faq/basic\\_information/population\\_growth\\_rate/latin\\_america.html](http://www.overpopulation.com/faq/basic_information/population_growth_rate/latin_america.html).

<sup>11</sup>Recall from above that the values of the parameters  $\gamma$ ,  $n$ , and  $\delta$  are about the same. Regarding  $\theta$ , Gollin

implies that the Latin American capital-labor ratio gap is entirely accounted for by its 50 percent TFP gap:

$$(2) \quad \frac{\left(\frac{K}{L}\right)^{Latin}}{\left(\frac{K}{L}\right)^{US}} \approx \eta^{1/(\theta-1)} = 0.36.$$

TFP is the efficiency with which an economy uses its capital and labor services. The following sections evaluate some possible factors that might account for Latin America's TFP gap, including human capital and barriers to competition. We will focus our empirical evaluation on whether these factors can account for Latin America's 50-year relative TFP stagnation.

## 5. Human Capital Is Not a Major Factor

Our analysis has measured labor services as employment, without any adjustment for differences in human capital between regions. This suggests that differences in measured TFP across countries may in part be due to differences in human capital. It is important to know how much of Latin America's TFP stagnation is due to human capital, because optimal government policies, and how fast they impact the economy, may likely depend on how much of Latin America's TFP gap is due to human capital.

If human capital differences are the main stagnation factor, then we should observe Latin America's relative human capital stagnating and human capital in the European and Asian countries rapidly catching up to the United States. Moreover, a human capital-based explanation makes two other empirical predictions: (1) Latin America should have a very low ratio of human capital to output compared to the United States, and (2) Latin American TFP levels should be similar to those in the United States after adjusting TFP for human capital differences between the two regions. We will show that neither of these predictions is consistent with the data.

Regarding TFP as a stagnation factor, Table 7 shows relative human capital levels in

---

(2002) shows that income shares are quite similar across countries once uniform accounting procedures are used to allocate entrepreneurial income. We assume that differences in  $\beta$  are small, because otherwise the rate of return to physical capital in Latin America would systematically be much higher than in the United States. We are unaware of evidence supporting this view.

1960 and 1990 for Latin America and the other regions using Bils and Klenow's (2000) human capital measures. The patterns in this table don't account for the very different patterns in output per worker over time between Latin America and the other regions, because human capital in *all* the regions is catching up to the U.S. level, and Latin America's increased the most. Specifically, Latin America's relative human capital increased by 19 percent between 1960 and 1990, Europe's increased by 12 percent, and Asia's increased by 9 percent. These changes suggest Latin America should have had the fastest catch-up of the three regions. This prediction stands in sharp contrast to the actual patterns of development.

The Bils-Klenow data suggest that human capital is not the factor that distinguishes the development successes in Europe and Asia from Latin America's stagnation. The fact that Latin America's relative output continues to decline, despite this significant increase in human capital, indicates that a different factor is driving down Latin American relative TFP and output. Moreover, the fact that Europe and Asia have gained 30 and 40 percentage points, respectively, on the United States, despite only about 10 percentage point catch-ups in human capital, suggests that another factor is driving these successful countries.

This conclusion is robust to measuring human capital using average years of schooling. For example, the relative years of schooling in the population aged 25 and older in Latin America rose from 36 percent of the U.S. level in 1960 to 41 percent in 1990. During the same period, Europe's relative educational attainment fell from 69 percent of the U.S. level in 1960 to 63 percent in 1990, while our Asian countries rose from 62 percent in 1960 to 67 percent in 1990. As with the Bils-Klenow data, these changes do not account for why Europe and Asia are development successes, and why Latin America has stagnated.

Country-level schooling measures also support this view, because some Latin American countries have a higher average schooling attainment than many of the Asian and southern European development successes. In Argentina, Chile, and Uruguay, for example, the average years of schooling of the population aged 25 and over was 7.8, 6.2, and 6.7, respectively, in 1990, which exceed the average number of years of schooling of 3.6 years in Portugal, 6.3 years in Spain, and 5.5 years in Singapore. Despite more years of schooling, income in these Latin American countries is much lower than income in these other countries. Output per adult as a fraction of U.S. income in Argentina, Chile, and Uruguay was 29 percent, 36 percent, and

27 percent, respectively, in 2001, while relative per capita income in Portugal, Spain, and Singapore was 51 percent, 56 percent, and 75 percent, respectively.

A second reason that human capital is not the key factor is Latin America's relative ratio of human capital to output. Specifically, if human capital were the key factor, then Latin America should have a relatively low ratio of human capital to output, just as if physical capital were a major factor behind Latin America's low labor productivity, then Latin America should have a relatively low ratio of physical capital to output. In contrast, Latin America has a very high relative supply of human capital. In particular, the Bils-Klenow data imply that Latin America's human capital-output ratio is 140 percent higher than that in the United States. For comparison, we note that Europe's ratio is about the same as the U.S. ratio.

A third reason that human capital is not the central factor accounting for Latin America's TFP gap is because a large gap between the United States and Latin America remains after adjusting for human capital differences. Klenow and Rodriguez-Clare (1997) and Hall and Jones (1999) construct income level accounting in a single year for the countries in the Penn World tables, including Latin America. Hall and Jones (1999) find an average TFP level in our set of Latin American countries of 58 percent of the U.S. level in 1988, after adjusting for human capital. Klenow and Rodriguez-Clare, using 1985 data and some different procedures, find that these countries have an average of 67 percent of U.S. TFP. Averaging these two single-year TFP gaps suggests that human capital accounts for only about a quarter of the 50 percent postwar average Latin American TFP gap we calculated in the preceding section.

We conclude that human capital is not the major factor in explaining Latin America's TFP gap, nor does it appear to play an important role in Latin America's long-run stagnation. This is because while Latin American human capital is increasing over time, its labor productivity is falling. Our view that there is an alternative factor retarding Latin American development is similar to conclusions about the role of human capital in the development process reached by a number of other authors, including Prescott (1998), Easterly (2001), Parente and Prescott (2000, 2004), and Hendricks (2002). We consider this other factor to be inefficient production, either through the failure to adopt superior technologies, or through

the inefficient use of technologies. A key implication of this inefficient production view of low TFP—as opposed to the human capital view—is that productivity and output can rise quickly in response to higher efficiency. We will later see in a number of industry studies that this is indeed the case.

## 6. Latin American Stagnation and Competitive Barriers

A very old view, extending back to at least Adam Smith, argues that barriers to competition will discourage innovation. According to this view, countries that have more competitive barriers will be poorer. We will argue empirically that barriers to competition are at least part of the reason Latin American producers are systematically and persistently less efficient than U.S., European, and Asian producers.

Before conducting this analysis, we note that this channel between competition and productivity is one of the leading channels for understanding low productivity in the theoretical TFP literature. A number of economists are now developing formal models that generate low productivity as an outcome of competitive barriers. A key challenge in these models is to rationalize why societies choose to be unproductive. A major rationalizing element in these models is that a subset of society would be harmed by the adoption of superior technologies, and this subset has sufficient resources to successfully block their adoption. For example, Holmes and Schmitz (1995) present a model in which groups in an industry have the potential to block a new technology by political lobbying for new regulations. The group has skills tied to an old technology that will become obsolete if the new technology is adopted. The group decides whether to use its resources to block or to learn the new technology. The paper shows that the group is much less likely to block if the industry is subject to competition from other countries. Other papers that have developed models in which groups may choose to block technology adoption include Parente and Prescott (1994, 1999), Holmes and Schmitz (2001), Cozzi and Palacios (2003), Bridgman, Livshits, and MacGee (2004), and Herrendorf and Teixeira (2004).

In all of these papers, lowering competition reduces productivity through the channel of “X-inefficiency,” in which an organization fails to produce at its minimum cost. However, there are other channels through which low competition can lead to low efficiency. For exam-

ple, the government may impede entry by more efficient firms in order to protect incumbent, low efficiency producers who politically support the government. This view is consistent with that of Sokoloff and Engerman (2000), who argue that the political elite are the leading groups in Latin America that restrict competition. In the next section we establish that Latin America erects significantly more competitive barriers than the successful countries in Europe and Asia. We will then show that changes in the degree of competitive barriers in Latin America have large and systematic effects on productivity.

## 7. Latin America Puts Up Significant Competitive Barriers

We now focus on government policies that restrict competition. We do this because of our view that policy is central for sustaining persistent competitive barriers. We will examine a number of different types of barriers that we categorize as either *international competitive barriers*, including tariffs, quotas, multiple exchange rate systems, and regulatory barriers to foreign producers, and *domestic competitive barriers*, including entry barriers, inefficient financial systems, and large, subsidized state-owned enterprises.

We will present evidence that shows that Latin America has constructed many international and domestic barriers that have closed off Latin America from both internal and external competition. Both the *breadth* and *depth* of Latin American barriers significantly exceed those in Europe and other successful countries. The breadth and depth of Latin American barriers are important, because the impact of competitive barriers rises nonlinearly with the number of barriers that are adopted. More specifically, competitive barriers are complements. For example, we will show that Latin America has regulations that significantly raise domestic entry costs. Moreover, we will show that Latin America also has had high tariffs, which protect Latin American producers from foreign competition. By insulating domestic producers from foreign competition, tariffs are a complementary noncompetitive factor that raises the noncompetitive effects of high domestic entry costs. Our documentation of Latin American barriers is consistent with Sokoloff and Engerman's (2000) overall view that politically connected groups in Latin America restrict competition.

### **A. Latin America's International Barriers: High Protectionism**

Latin America has a long history of erecting international competitive barriers to protect domestic industries that date back to at least the late 1800s. (See Clemens and Williamson 2002 and Haber (forthcoming).) These barriers include quotas, multiple exchange rate systems, and, in particular, high tariffs.

We now present historical data on these barriers. Before we proceed, it is important to recognize that measuring the effective level of competitive barriers is difficult, not only because of the complementary interactive effects of multiple barriers discussed above, but also because of other measurement problems. For example, some tariff measures are the average of tariff revenue over the value of imports. This does not measure the extent of effective protection since the overall cost advantage secured by domestic producers from the tariff barrier is enhanced by tariffs on their product but lowered by tariffs on their inputs. Similarly, quota measures are typically the fraction of goods subject to a quota, but this fraction does not measure the extent to which the quota is distortionary.

Clemens and Williamson show that Latin American tariff rates were systematically higher than those in other parts of the world as far back as the 19th century. They report that Latin America had average tariff levels of 27 percent between 1870 and 1913, compared to an average level of 7 percent in Asia over the same period. Latin America's tariff rates rose substantially in the 20th century, particularly after World War II. There are large differences in the pattern of tariffs between Latin America and Europe during the post-World War II period that are consistent with Europe's rapid catch-up to the United States and that are also consistent with Latin America's stagnation.

Between 1950 and 1980, Europe gained about 30 percentage points on the United States. Tariffs in European countries were low. This "golden age" of catch-up bypassed Latin America, however, which gained only 2 percentage points on the United States during this period. In contrast to those in Europe, Latin American tariffs were high. Table 8, reproduced from Taylor (1996), shows that Latin American tariffs were systematically and substantially higher than those in Europe during this period. The table shows Taylor's estimates for nominal protection for a number of Latin American countries and for the average of the European Economic Community. The table shows that Latin American tariffs are almost

always much higher than the EEC tariff across all categories of goods: consumer durables, consumer nondurables, semimanufactured goods, raw materials, and capital goods.

The EEC protection rates range between 1 percent and 13 percent, and the unweighted average tariff rate for the EEC countries is about 10 percent. In contrast, the unweighted average rate for five of the six Latin American countries ranges from 68 percent to 172 percent. Protection rates are particularly high on consumer goods, including rates of 176 percent in Argentina, 260 percent in Brazil, 328 percent in Chile, 247 percent in Colombia, and 114 percent in Mexico on nondurables. Protection rates are also surprisingly high on capital goods, including rates of 98 percent in Argentina, 85 percent in Brazil, and 45 percent in Chile. We view these rates as surprisingly high, because optimal tax theory in a number of models predicts that capital accumulation decisions should not be distorted in the long run. This theoretical conclusion implies that capital goods imports should not be subject to tariffs.

In addition to these high tariffs, Latin American countries also made significant use of quotas during this period. For example, Haber (forthcoming, p. 50) reports that the number of imported goods subject to quotas rose from 28 percent in 1956 to 74 percent by 1974.

Relatively high protectionism in Latin America persisted until the early 1990s. Loayza and Palacios (1997) show that average tariff rates in Latin America were about 38 percent between 1984 and 1987, compared to 16 percent for East Asia. Between 1988 and 1992, Latin American tariffs averaged 27 percent, compared to 15 percent in East Asia. By the mid-1990s, the two regions had roughly similar tariff rates. These authors also show that high nontariff protectionism also persisted until the mid-1990s.

Latin America's high protection levels should have closed off the region to competition and reduced international trade. We will next show that our development success countries in Europe and Asia tend to be much more open than Latin America. We define openness as the trade share, which is the sum of imports and exports divided by GDP. Following Eaton and Kortum (2002) and Alvarez and Lucas (2004), we plot the log of the trade share against the log of GDP. The idea here is that countries that are small—those that have small total GDPs—trade more than countries that have very large total GDPs. Figures 7–10 show these plots for the 1960s, 1970s, 1980s, and 1990s. Both the GDP and trade share data are decadal

averages, where  $\overline{TS}_{it}$  is the decadal average trade share for country  $i$  and  $\overline{GDP}_{it}$  is the decadal average GDP for country  $i$ . The figures also include a regression line for the cross-section of countries from the following regression that is estimated individually for each decade:

$$\overline{TS}_{it} = \alpha_0 + \alpha_1 \overline{GDP}_{it} + \varepsilon_{it}.$$

The figures systematically show that most of the Latin America countries are below the regression line, meaning they are less open than predicted by the statistical relationship, and most of the European and Asian countries are above the regression line, meaning they are more open than predicted by the statistical relationship. This means that the development success stories are persistently and systematically more open than the Latin American development failures.

This finding stands in contrast to the openness-growth literature, in which there is no clear-cut empirical relationship between these two variables.<sup>12</sup> The Holmes and Schmitz (1995) model provides two explanations for why there is a systematic relationship for our Latin American countries, but no systematic relationship in the openness-growth literature. This is because (1) the impact of openness depends critically on the level of domestic competitive barriers, and (2) the relationship between openness and productivity *levels* may be quite different from the relationship between openness and productivity *growth*.

Regarding the first explanation, lack of openness in the Holmes-Schmitz model is important only if a country also has high domestic competitive barriers. The next section documents that Latin America satisfies these criteria. The second reason is that there is an important connection between openness and productivity *levels* in the Holmes-Schmitz model, but not necessarily between *productivity growth* and openness. In the language of our model, this means openness can affect the level of  $\eta$  in a country, and this permanent change in  $\eta$  would be associated with temporarily higher growth associated with transitional capital accumulation dynamics. Our Latin American countries are therefore interesting because they have had low productivity, low openness, and high domestic barriers in each of the decades we

---

<sup>12</sup>See Rodriguez and Rodrik (2001) for a survey of this literature and Rigobon and Rodrik (2004) for a very recent analysis that finds a small positive relationship between openness and growth.

consider. These are precisely the countries in which openness should matter for productivity growth, even if the productivity growth is just a temporary transition to a new level.

## **B. Latin America’s Domestic Competitive Barriers: High Entry Barriers**

Latin America has systematically higher domestic competitive barriers than the European and Asian successes, including (i) high entry costs, (ii) poorly functioning capital markets, and (iii) high costs of adjusting the workforce or building up an experienced workforce. Entry costs can be an important competitive barrier because they reduce the incentive for firms to enter an industry. Djankov et al. (2002) present data on the costs of starting businesses for 85 countries. The data are from 1997. They estimate the entry cost by summing the individual costs of all the requirements for establishing a “representative” business in the formal sector, including the opportunity cost of the entrepreneur’s time, and the direct pecuniary cost of these requirements, such as filing fees and license fees.

Table 9 shows the total entry costs for Europe, Asia, and Latin America. The estimates show that the United States has the lowest entry costs and that Latin America has the highest entry costs. In particular, the total cost of entry is 80 percent of per capita GDP in Latin America, compared to just 1.7 percent in the United States. These data suggest that entry costs are indeed much higher in Latin America, and constitute a potentially important competitive barrier.

Poorly functioning capital markets that impede the capital accumulation of new entrants or smaller firms—and prevent them from competing with larger more established, and often more politically connected, firms—are a potentially important barrier to competition, particularly if entry costs are high and entrepreneurs are liquidity constrained. The extent of government ownership of banks is regarded as an important indicator of how bank lending is preferentially directed to politically connected enterprises. Table 10 shows that Latin America’s government ownership share is higher than the European countries’, and much higher than in our Asian countries or in the United States, where this share is zero. These data are from La Porta, Lopez-de-Silanes, and Shleifer (2002).

Latin America also has adopted labor market regulations that impede the ability of firms to acquire the efficient level and composition of their workforce. In summarizing the

results of a collection of studies on Latin American and Caribbean (LAC) labor markets, Heckman and Pages (2003) conclude that while the overall costs of labor market regulation are quite similar in LAC and OECD countries, the LAC countries impose these costs much more in the form of job security measures than in social security provisions. Heckman and Pages conclude that the higher LAC job security costs “likely impair productivity and adaptation to new technology ...” (p. 38). In Table 11 we show one key aspect of the higher Latin American job security costs. That table documents that Latin America imposes much higher dismissal costs (measured in terms of months of the worker’s wage) than Europe or Asia, or the United States where these costs are zero. High costs associated with reallocating workers from less productive to more productive enterprises could constitute an important barrier to competition. Davis and Haltiwanger (1992) have documented the large extent of this worker reallocation in the United States. Hopenhayn and Rogerson (1993) have shown in a quantitative-theoretic model that costly worker reallocation can have significant effects.

This section has examined a number of competitive barriers in Latin America, Europe, East Asia, and the United States. In every case, Latin America has the highest barriers. Given the complementary interactive effects between these barriers, we conclude that Latin America has much higher protection rates for their producers than Europe, East Asia, or the United States.

## 8. Microeconomic Evidence on the Impact of Competition

We now present microeconomic evidence from Latin America that shows how productivity and output change when there is a change in competition. Before proceeding, we note that a number of studies have documented that lack of competition and low productivity go hand-in-hand. (See McKinsey Global Institute 1994 and IMD 2004.) For example, the McKinsey studies show that productivity is high when firms face international competition. Baily and Solow (2001) review the McKinsey evidence and interpret this correlation between competition and productivity as one in which competition drives productivity:

“An implication [of the McKinsey finding] is that some part of observed productivity disadvantages reflects organizational slack or an unwillingness to change and innovate. This corresponds to the belief, expressed by managers, that when

pressed by competition they can ‘take some of the cost out of the product.’”

However, Baily and Solow acknowledge that the correlation is open to an alternative interpretation: more productive industries choose to compete globally. The possibility of different interpretations of this barrier-productivity correlation is much less of an issue when the approach of Galdon and Schmitz (2002) and Schmitz (2004) is used. They conduct industry-level analyses in which there is a large, exogenous change in competition, and in which productivity is easy to measure both before and after the competitive change. For example, Schmitz (2004) finds that when Minnesota iron ore producers faced increased foreign competition brought about by exogenous changes in the world steel market, their work practices (the rules that governed employee tasks) changed to achieve a 100 percent increase in labor productivity.

We follow this approach here by presenting industry cases in which there are large and exogenous government policy changes that significantly affect the level of competition. Some of these cases will show what happens when anti-competitive policies are adopted. We first present two cases that show the adoption of nationalization policies that destroy competition by eliminating international firms from an industry are associated with large and permanent productivity and output losses. We then present five cases that show the adoption of policies that foster competition are associated with large productivity and output gains. The pro-competitive policies include the privatization of state-owned enterprises, the elimination of trade impediments, such as quotas, and the elimination of restrictions on the entry of international firms.

We will show that the different policy changes affect two types of competitive barriers. We call the first type of barrier *entry impediments*, which keep high productivity firms out of an industry. We call the second type of barrier *incentive impediments*, which reduce the incentives for firms within an industry to be efficient.

### **A. Eliminating Competition in the Venezuelan Oil Industry**

We now provide an important case where nationalization eliminated foreign competition and reduced productivity substantially in a major sector. Our discussion draws on recent work by Restuccia and Schmitz (2004). Before World War II, Venezuela had substan-

tial foreign investment in its oil industry. This policy changed with the election of the *Accion Democratica* (AD) party in 1945. The party pushed for greater Venezuelan sovereignty in the industry, culminating in decisions in the late 1950s to terminate international rights to extract oil beyond 1983. This meant a *de facto* nationalization of the industry at that date. Not surprisingly, this policy change led to a decline in foreign investment in the industry. This declining investment then led the AD party to nationalize the industry earlier. The nationalization of the Venezuelan oil industry was completed on January 1, 1976. Although industry officials fought to retain foreign managers after the nationalization, the government preferred to sever all international ties and largely succeeded in driving out most of the industry's foreign experts.

Figure 11 shows output and labor productivity in the Venezuelan oil industry before and after nationalization. Before 1970, output and productivity rose considerably, growing at rates of about 4.5 percent and 7.5 percent, respectively. Output and productivity began to decline after 1970 and fell sharply just before the nationalization. By the time of the nationalization in the mid-1970s, productivity had returned to its 1964 level and output had returned to its 1957 level.

Output and productivity continued to fall after the nationalization. By 1985 productivity had fallen over 70 percent from its 1970 peak, and was at its 1955 level. Output fell 53 percent between its peak in 1970 and 1985, and was also at its 1955 level. It is striking that the large output loss was accompanied by an increase in employment, which suggests that the local managers were not nearly as efficient at running the operation as the foreign managers. Moreover, this output loss is not the result of OPEC policies; many OPEC members increased their output considerably in the 1970s and 1980s, which stands in sharp contrast to Venezuela's production during this period. Output and productivity recovered modestly after the 1985 trough, but remained well below their peak levels. By 1995, which is the ending year for our data, output had returned only to its 1963 level, and productivity had returned only to its 1960 level.

We conclude that nationalization of the Venezuelan oil industry, which eliminated the efficient international management of the industry, led to large productivity and output losses. Restuccia and Schmitz argue that a significant fraction of this productivity loss was

due to the loss of international expertise.

## **B. Eliminating Competition in the Venezuelan Iron Industry**

Restuccia and Schmitz (2004) also show that Venezuela followed a similar nationalization policy with its iron ore industry, with similar results. Figure 12 shows output and labor productivity in the Venezuelan iron ore industry before and after nationalization. The output and productivity patterns mirror those from the oil industry. Both output and productivity rose significantly until just before nationalization, with output growing at 6.1 percent per year and productivity growing at 11.5 percent per year from 1953 to 1974. Both output and productivity fell 50 percent between 1974, which is just before the nationalization, and 1976, which is the first year after nationalization. By 1983, output was 62 percent below its 1974 peak level and productivity was 58 percent below its peak level. As in the case of oil, output and productivity recovered modestly, but remained well below their pre-nationalization peaks. By 1995, both output and productivity were 30 percent below their 1974 levels.

We now turn our attention to the impact of policy changes that increase competition.

## **C. Allowing Entry in Chile's Copper Industry**

We first show that bringing foreign competition to Chile's copper industry is associated with a large and permanent increase in productivity and output. We will show that Chile's policy change, which reversed its 1971 nationalization of the industry, reduced both entry and incentive impediments.<sup>13</sup>

Copper is a major Chilean industry, accounting for about one-third of exports and about 10 percent of GDP. In 1971, the largest Chilean copper mines, accounting for about 85 percent of production, were nationalized and subsequently operated by a government-owned firm, Codelco. Ten percent of Codelco's revenues were paid directly to the military. The remaining output was produced by small, privately owned mines. The key outcome of the nationalization is that Codelco faced very little foreign or domestic competition. Despite some reforms by Pinochet to encourage foreign investment in the 1980s, there was very little

---

<sup>13</sup>The material in this section draws from Aydin and Tilton (2000), Garcia, Knights, and Tilton (2000, 2001), and Tilton (2002). We thank John Tilton for providing us with his data.

foreign entry, and Codelco maintained its very high market share.<sup>14</sup>

In 1990, the Pinochet government was replaced by a civilian government that was committed to supporting reforms, and at about the same time, copper prices rose. This led to a substantial increase in foreign entry. Figures 13 and 14 show how output, productivity, and Codelco's industry share changed with the introduction of foreign competition. Total copper output increased 175 percent between 1990 and 2000, which is a growth rate of over 11 percent, compared to a growth rate of about 4.5 percent between 1970 and 1990. Much of this output increase came from entrants, as Codelco's output share dropped from 75 percent in 1990 to 33 percent by 1999. Figure 14 shows that productivity increased substantially after the introduction of foreign competition. Productivity increased by a factor of more than 3.5 over the 1990s, which is a growth rate of 14 percent per year, compared to a growth rate of 3.5 percent per year before 1990. Garcia, Knights, and Tilton (2001) show that about 30 percent of the productivity gain was from higher efficiency at individual mines, while 70 percent of the gain was from shifting location, that is, from the production of new entrants. The fact that productivity grew faster than output indicates that the industry was able to produce more output with fewer workers.

Figure 15 shows that Chile's rapid post-reform productivity growth significantly reduced the labor productivity gap between Chile and the United States. Before the reform, Chile's relative productivity deteriorated from 41 percent of the U.S. level to about 30 percent of the U.S. level. After the reforms, Chilean productivity increased from 30 percent of the U.S. level to 82 percent of the U.S. level over a 10-year period.

The figure also shows that U.S. productivity was roughly unchanged for five years before the reforms and for five more years after the reforms. This fact suggests there were no frontier technological breakthroughs, which provides further evidence that competitive reforms were the main cause of Chile's large productivity catch-up. This suggests that the new, private entrants increased productivity by (1) mining better deposits, (2) using a superior technology (that was available before 1990), or (3) having better expertise. The important

---

<sup>14</sup>The Constitutional Mining Law, adopted in 1982, ostensibly provided foreign investors protection in the event of future confiscations, but the law came under attack by the political opposition. Perhaps not surprisingly, there was very little new foreign investment in the industry.

point is that all of these factors were available to Latin America before the reform. The competitive reforms also led to a productivity increase at Codelco, which owned and operated four large mines. Between 1990 and 1997, productivity rose by 37, 70, 70, and 84 percent at these mines. These large productivity gains suggest that the nationalization policy also dulled the incentives for incumbent producers to be efficient. Despite Codelco's productivity gains, there was a significant reallocation of production from Codelco to the most efficient producers. This large loss of market share suggests that Codelco may not have survived in any form had it not been able to realize these efficiency gains after the industry reforms.

We conclude that pro-competition policy reforms that encouraged foreign competition significantly increased productivity in the Chilean copper mining industry by allowing high productivity producers to enter and by changing the incentives facing the incumbent producers. In particular, this case shows that even large and persistent productivity gaps in quantitatively important sectors can be eliminated quickly when policy fosters competition.

#### **D. Reversing Quotas in Brazil's Computer Industry**

We now show how eliminating a zero quota policy in Brazil's computer industry is associated with a large increase in output and productivity. We will show that lifting the import ban on foreign-produced computers reduced both entry and incentive impediments in the industry. Our discussion draws on work by Luzio and Greenstein (1995) and Botelho et al. (1999).

In 1977, Brazil embarked on a "market-reserve" policy for its personal computer and minicomputer producers. This meant that only PCs and minicomputers produced by Brazilian-owned firms could be legally sold in Brazil.<sup>15</sup> While there undoubtedly were illegal purchases of imports by small firms and individuals, Luzio and Greenstein document that the black market was not a practical choice for large firms. The policy thus insulated Brazilian computer producers from foreign competition, and the policy also featured entry barriers to new firms through a maze of bureaucratic requirements. The policy also provided protection for upstream component producers through domestic content laws that required Brazilian computer makers to use domestically produced components, including silicon chips, picture

---

<sup>15</sup>There were some provisions for production by local firms in joint venture with foreign firms.

tubes, and other standard parts. The prices of these Brazilian components were two to five times higher than international prices. The policies also restricted entry into the component supply industries. (See Luzio and Greenstein 1995, p. 624.)

Under the quota policy, the Brazilian computer producers were not competitive with international producers. Brazilian computer prices were 70 to 100 percent above international prices after the policy was adopted. Support for this policy evaporated, and after the 1990 presidential election, President Collor phased out this market-reserve policy by 1992. The new policy eliminated the quota, included tariffs of about 30 percent, and provided some tax incentives for foreign firms to produce PCs in Brazil (Botelho et al. 1999, pp. 9–10). The abandonment of the zero quota policy coincided with large price declines, large output increases, and large productivity increases. Computer prices fell 43 percent per year from 1990 to 1992, compared to an 18 percent annual decline before Collor’s election. Moreover, prices fell substantially immediately after Collor’s election.

Luzio and Greenstein use these price declines to infer productivity changes in Brazil’s computer industry. They estimate that Brazil had a 6-year relative technological gap to the United States in 1989. That is, the efficiency of Brazil’s producers in 1989 was equivalent to U.S. producers in 1983. Since productivity growth in the U.S. computer industry has been estimated to be around 30 percent per year,<sup>16</sup> this means that Brazil had only about 20 percent of the U.S. productivity level in 1989 prior to the reforms. Brazil was able to eliminate one-third of its productivity gap, however, between 1990 and 1992. This is striking, given the very rapid productivity advancements occurring in the United States.

The policy reform also is associated with a large increase in domestic production. From 1992 to 1998, output increased by about 100 percent, compared to just a 33 percent increase from 1985 to 1992.<sup>17</sup> (See Botelho et al. 1999, Fig. 1.) This post-1992 output increase is probably understated because the sales figures are measured in dollars, and prices were falling much faster after 1992 than during the 1985–92 period.

Imports rose 150 percent with the new policy, but despite this increase in foreign

---

<sup>16</sup>Source: <http://www.bls.gov/opub/ted/2000/Dec/wk1/art02.htm>.

<sup>17</sup>The figures we have for local production are for computer hardware, which includes PCs, minicomputers, mainframes, and peripherals. Foreign mainframe production was allowed in Brazil before 1992.

competition, many of the Brazilian firms were able to successfully compete. Following the policy change, 6 of the top 10 producers were Brazilian firms. We conclude from this case that increasing competition led to large productivity and output advances. The fact that Brazilian firms raised productivity substantially and quickly after the removal of the quota policy suggests that the quota policy retarded the incentives for firms to be efficient.

### **E. Privatizing State-Owned Enterprises: Brazilian Iron Ore**

We next analyze the privatization of the Brazilian iron ore industry. Our discussion draws on the work of Schmitz and Teixeira (2004). We will show that the privatization of this industry removed both entry and incentive impediments and substantially raised productivity.

Brazilian iron ore was historically produced by both state-owned enterprises and private firms. In 1990, SOEs accounted for about 60 percent of production and private firms about 40 percent. The state-owned portion of the industry was composed of two firms: CSN (Cia. Siderurgica Nacional) and CVRD (Companhia Vale do Rio Doce). Almost all of the SOEs' production was accounted for by CVRD, which at that time was the largest iron ore producer in the world. CSN was primarily a steel producer and owned only one small iron ore mine. Privatization began in 1991 when CSN sold its small mine to private investors. Plans to sell CVRD also began in the early 1990s, and this led CVRD to change its organization structure in preparation for privatization.

One of the key organizational changes was in the rules that governed the allocation of tasks across employees. Prior to privatization, work rules placed significant limitations on the number of tasks a worker could perform. Specifically, workers had specialized job classifications that permitted them to perform only a very small set of tasks. For example, machine operators were prohibited from making any adjustments or repairs to their machines, even though some of these repairs were trivial. Schmitz and Teixeira argue that this work rule policy depressed productivity through similar channels as in Schmitz' (2004) study of the U.S.-Canadian iron ore industry.

These work rule restrictions were removed when CVRD prepared for privatization in the early 1990s. Schmitz and Teixeira (2004) report that interviews with company and union officials indicate that the threat of privatization weakened the union, which led to the changes

in work rules. The privatization of CVRD was completed in 1997 when it was purchased by local entrepreneurs.

Figure 16 shows output and productivity in the industry between 1971 and 1997. Note that there was almost no productivity growth between 1973 and 1990. Productivity begins to grow at the onset of privatization, culminating in a 30 percent increase in 1997 when the privatization of CVRD is completed. Productivity grew about 140 percent between 1990 and 1997, and output grew about 30 percent during this period. As in the case of the Chilean copper industry, the Brazilian iron ore industry produced more output with significantly fewer workers following the policy reform.

Figure 17 decomposes overall industry productivity into the productivity at CVRD's northern and southern operations and the productivity of the private producers.<sup>18</sup> Productivity at both of the CVRD divisions began growing in 1993, and productivity in the private mines began growing in 1995. The productivity at all three sets of plants grew between 110 and 130 percent between 1990 and 1998. The increase in CVRD's productivity is the result of removing the entry impediments in the industry, as a more efficient group of managers operated the mines following the privatization. The increase in productivity at the incumbent private mines is the result of removing efficiency impediments in the industry, as these mines had to compete with a more efficient CVRD.

We conclude from this case that privatizing the industry led to large productivity gains both at the newly privatized firms and at the firms that had to compete with the privatized firms.

## **F. The Large-Scale Privatization of Mexican SOEs**

We now explore larger-scale Latin American privatizations. We begin with Mexico's privatization of most of its SOEs, which began in 1983. Our discussion draws on work by La Porta and Lopez-de-Silanes (1999). We will present data that show privatization of state-owned businesses is associated with large output and productivity gains.

Prior to the early 1980s, state-owned enterprises (SOEs) played a significant role in the Mexican economy. They accounted for about 14 percent of GDP and about 38 percent

---

<sup>18</sup>Data are available only beginning in 1986.

of capital investment. These state-owned enterprises operated in a wide range of industries in manufacturing, mining, and services. Within manufacturing, these enterprises included producers in textiles, chemicals, heavy machinery and equipment, electronics, autos, and transport equipment.

These enterprises, however, were very inefficient. They received transfers and subsidies totaling 13 percent of GDP, which means they were just barely positive value-added organizations. After 1983, almost all of these enterprises were sold to private bidders. La Porta and Lopez-de-Silanes (1999) analyze the impact of this privatization process by studying the pre- and post-privatization performance of 170 Mexican state-owned enterprises in 49 industries. The privatizations occurred over the 1983–91 period. They find that output and productivity rise substantially following privatization. Mean real sales rise 54 percent, and median real sales rise 68 percent. What is even more striking is that these large output increases occur despite large labor reductions. Figure 1 in their paper shows that the average employment level of these enterprises fell by more than half after privatization.

Other performance measures also improve substantially after privatization. Tax collections from these enterprises rise from  $-4.6$  percent of pre-privatization sales to 8.4 percent of post-privatization sales. The median ratio of operating income to sales rises from  $-2$  percent before privatization to 9 percent afterward, and the median ratio of net income to sales rises from  $-13$  percent to 7 percent. Both of these post-privatization profitability ratios are comparable to those of publicly traded, private firms in Mexico, and nearly 60 percent of these increases in income are accounted for by higher productivity.

Since the reforms occur during a period of rapid economic growth in Mexico, the authors also compare post-privatization performance of the SOEs with the performance of incumbent private firms. This comparison also shows that the recently privatized firms had much larger output and productivity gains than the incumbent private firms. It is worth nothing that La Porta and Lopez-de-Silanes did not try to account for the impact of privatization on the performance of the private incumbent firms, or the broader impact of the policy change on the aggregate economy. Analyzing these indirect effects would have led to even higher estimates of the effects of the privatization reforms.

We conclude that the privatizations led to large increases in productivity and output

for a significant fraction of the economy by removing entry impediments. As in the case of the Chilean copper industry and the Brazilian iron ore industry, output expanded substantially with significantly fewer workers.

### **G. The Large-Scale Privatization of Argentinian SOEs**

Argentina also privatized many of its SOEs in the 1990s. Galiani et al. (2001) study the privatization of these state enterprises. In contrast to Mexico, most Argentinian state-owned enterprises were large vertically integrated “natural” monopolies (e.g., electricity, transport, and communications). When the government sold the enterprises, it often kept the monopoly structure in the industry to make the firm attractive to prospective buyers. Hence, the productivity consequences of privatization might not have been as large under this strategy.

Galiani et al. use a method very similar to that used by La Porta and Lopez-de-Silanes (1999) in their study of Mexican privatizations. Even though many transferred enterprises continued to operate as a monopoly (albeit a private one), large performance gains resulted. The increases were not as large as in the more competitive Mexican cases, but were still significant. They find a median increase in labor productivity of 46 percent. They also find unit costs declined 10 percent and production rose 25 percent.

There is a common theme in these seven cases: policy changes that substantially affect the amount of competition faced by Latin American producers significantly and systematically change productivity. In particular, these cases suggest that Latin America indeed can achieve Western productivity levels when competitive barriers are removed.

## **9. Conclusion**

Latin America is a development outlier. This is because it is the only group of Western countries that are not already rich, or that have not gained significant ground on U.S. income levels in the last 50 years. In contrast, Latin America is falling further behind the United States and the other economic successes. Latin America is a development failure because its TFP has failed to catch up. Our analysis suggests that its TFP stagnation is not due to a human capital stagnation, but is rather due to idiosyncratic and long-standing Latin American choices that have impeded either the adoption of superior technologies or the most efficient use of technologies.

We have argued that competitive barriers are a promising route for understanding Latin America's large and persistent productivity gap. This is because Latin America systematically sets up significantly more impediments to competition than the United States, Europe, or East Asia, and these impediments are associated with low productivity. Specifically, we found that Latin American policy changes that eliminated competition are associated with large and permanent declines in productivity and output, and conversely that Latin American policy changes that increased competition are associated with large increases in productivity and output in a set of industries.

The key implication of our findings is that Western-level productivity success is indeed feasible for these Latin American producers. In particular, when competitive barriers are eliminated and Latin American producers face significant foreign competition, they are able to replicate the high productivity levels of other Western countries. The key open question is whether increasing competition in other Latin American industries would also lead to such large productivity and output gains. More work is needed to address this question, but if the answer is yes, then understanding the reasons Latin America has set up so many competitive barriers is central. Potentially interesting avenues for addressing this latter question may include high inequality, as documented by Sokoloff and Engerman's (2000) and Acemoglu et al.'s (2004) general arguments about institutional design.

We hope that these findings stimulate further work on the importance of competitive barriers in Latin America. A number of other industries could be analyzed using this approach, including the privatization of the steel industry. We also hope that this stimulates work on identifying and evaluating other possible stagnation candidates. Our findings also have implications for these other factors. In particular, they suggest that any candidate factor must satisfy two criteria: (1) it must work through TFP, and (2) it needs to have been in place for at least the last 50 years. Candidate explanations that do not have these two characteristics are not likely to be the major culprits.

## I.1 Introduction

This book uses microdata from diverse Latin American and Caribbean countries to investigate the impact of regulation on their labor markets. Common methodologies are applied to extract empirical regularities from the region. Latin America and the Caribbean are of interest in their own right. But for several reasons, the lessons learned from studies of these labor markets have much greater generality.

The shifts in the policy regimes experienced in the region are dramatic by the Organization for Economic Cooperation and Development (OECD) standards, and many of these regime shifts are exogenous. This large and exogenous variation provides identifying power not available to analysts studying regulation in Europe and North America. Given the evidence on the comparability of labor demand functions around the world summarized in Hamermesh (1993 and chap. 11 in this volume), lessons about the impact of regulation learned from Latin American labor markets apply more generally.

The studies in this volume are based on microdata. Use of such data avoids reliance on fragile country aggregate statistics that have been the

James Heckman is the Henry Schultz Distinguished Service Professor of Economics and of Social Sciences, director of the Center for Social Program Evaluation at the University of Chicago, and a research associate of the National Bureau of Economic Research. Carmen Pagés is a senior research economist in the research department of the Inter-American Development Bank.

We thank Ricardo Avelino, Giuseppe Bertola, John Donohue, David Bravo, Fernanda Ruiz, Jagadeesh Sividasan, Sergio Urzua, and two anonymous referees for helpful comments. Heckman's contribution to this work was supported by the American Bar Foundation. The views expressed in this paper are those of the authors and not necessarily those of the Inter-American Development Bank or its board of directors.

main source of information used to study European regulation (see, e.g., the evidence summarized in Nickell and Layard 1999). Countries have diverse economic regions and agents, and aggregation over these regions and their economic agents masks this diversity. In this chapter, we show the sensitivity of estimates of the impact of regulation obtained from conventional pooled time series cross sections of countries to alternative choices of samples and models, although a few important empirical regularities established at the microlevel hold up in macrodata. Our analysis builds the case for doing disaggregated analyses of the type reported in this book.

The evidence presented here challenges one prevailing view that labor market regulations affect only the distribution of labor incomes and have minor effects on efficiency.<sup>1</sup> The results presented in this volume suggest that mandated benefits reduce employment and that job security regulations have a substantial impact on the distribution of employment and on turnover rates. The most adverse impact of regulation is on youth, marginal workers, and unskilled workers. Insiders and entrenched workers gain from regulation, but outsiders suffer. As a consequence, job security regulations promote inequality among demographic groups. Most of the individual country studies demonstrate that regulations promoting job security reduce covered worker exit rates out of employment and out of unemployment, and on balance reduce employment.

This introductory essay has three main goals: (1) It summarizes the main lessons to be drawn from the studies assembled here; (2) It places the Latin American and Caribbean (LAC) regulatory burden in an international context by comparing the level and changes in LAC labor regulation policies with those in OECD countries, as well as providing some historical context about the origins of this regulation; and (3) It updates the work of Heckman and Pagés (2000) with an expanded sample and better measures of regulation, providing a cross-country time-series analysis of the impact of regulation on employment and unemployment. We quantify the cost of regulation in LAC and OECD regions. The fragility of the macro-based estimates documented in our paper suggests one reason why relatively little is known about the impact of regulations in Europe, despite an abundance of cross-country time series papers analyzing policies in that region. However, the macro time series literature does produce some empirical regularities. The methods used to analyze the microevidence presented in this book should be extended to produce more convincing evidence of the impacts of regulations on employment in the OECD region.<sup>2</sup>

This chapter proceeds in the following way. Section I.2 provides background on Latin American economic and labor market performance. Sec-

1. Freeman (2000) and Nickell and Layard (1999), among others, adopt this view.

2. See, however, the studies of Abowd et al. (1997), Abowd, Kramarz, and Margolis (1999), Abowd et al. (2000), Machin and Stewart (1996), Kugler, Jimeno, and Hernanz (2002), and others, who use microdata to investigate the impact of regulation in Europe.

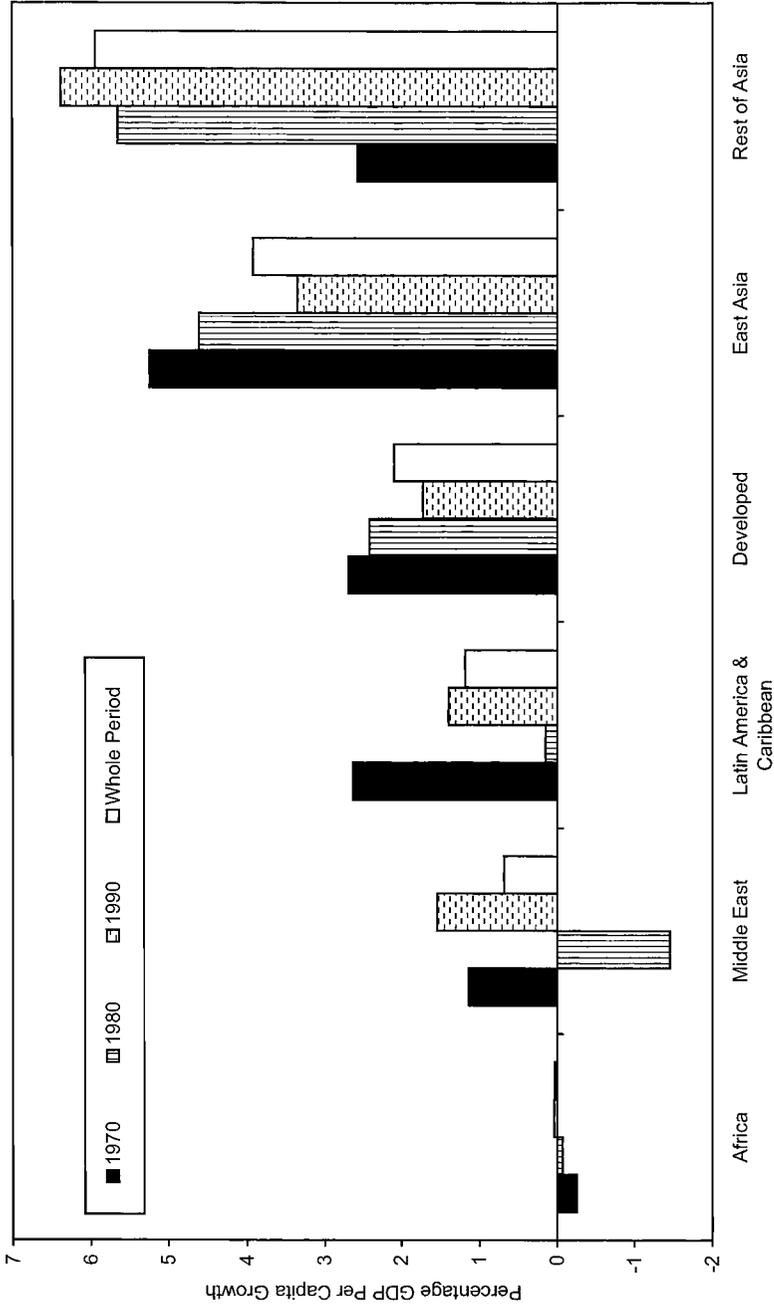

tion I.3 presents some basic facts about regulation in LAC and compares LAC with OECD countries both in terms of the level and composition of labor cost and in terms of the labor market reforms experienced in the region. Section I.4 summarizes the main lessons from the essays presented in this book. Section I.5 updates Heckman and Pagés (2000) and uses the cost measures derived in section I.3 to examine the impacts of labor regulation on Latin American and OECD employment and unemployment rates. Section I.6 concludes and makes suggestions for future work on regulation in Latin American and OECD labor markets. We first present some background on Latin America and the nature of labor market regulation in the region.

## **I.2 Latin American Economic and Labor Market Performance**

Latin American economic performance has been quite disappointing. Since 1970, growth of income per capita has been just over 1 percent per year, higher than in Africa or the Middle East, but much lower than in Asia or in the developed countries (figure 1). Up to the 1980s, trade policies heavily protected Latin American economies from foreign competition. There was a substantial degree of intervention by the state in the economy. The collapse of most economies during that decade due to growing fiscal and monetary imbalances led many countries to implement large structural reforms towards the end of the 1980s and early 1990s. Macroeconomic stabilization policies reduced fiscal deficits and brought inflation under control. Sweeping, fast-paced trade reforms lowered substantial tariff barriers on manufactured goods. Governments undertook fiscal reforms, lifted control over financial markets, and privatized most state-owned firms. Some countries also embarked on labor reforms described in the next section. While growth rates in the 1990s were higher than they were during the 1980s, the rates of growth in this period still fell short of those attained in other parts of the world.

Among the countries covered in this volume (Argentina, Brazil, Chile, Colombia, Peru, Uruguay, Barbados, Jamaica, and Trinidad and Tobago), Chile was the best performer, with an average growth rate of gross domestic product (GDP) of 4.8 during the period 1980–2001 (see table 1). Argentina and Trinidad and Tobago experienced the lowest average growth during the past two decades, despite high average growth rates during the nineties.

In spite of this weak economic performance, GDP per capita (purchasing power parity [PPP] US\$ adjusted) levels in Latin American countries are higher than those of other developing regions. According to the World Bank Development Indicators, in 2001 the average GDP per capita in the Latin America and the Caribbean region was \$7,050, considerably higher than that of East Asia and the Pacific (\$4,233), Central and Eastern Europe (\$6,598), South Asia (\$2,730), Sub-Saharan Africa (\$1,831) or the

*Notes:* Column (3) is measured in local currency at constant prices; in column (6) the Caribbean rates are not comparable to Latin American rates because they are computed with a different methodology.

Arab States (\$5,038). Similarly, the regional Human Development Index computed by the United Nations for LAC (0.77) was almost as high as in Central and Eastern Europe (0.78) and higher than in any other region except for the OECD (0.90). Among the countries whose labor markets are analyzed in this volume, Barbados and Argentina exhibited the highest income per capita and human development indexes, while Jamaica and Peru rank the lowest among the countries, both in per capita income and in human development (see table 1).

While GDP growth rates were not high, during the period 1980–1999 employment rates grew in the nine countries studied here. The highest growth rates were recorded in Colombia and Peru, countries that also experienced fast growth in female labor force participation. In contrast, average employment growth rates were low in Trinidad and Tobago and in Argentina. According to the International Labor Organization (ILO) and the Economic Commission for Latin America and the Caribbean (ECLAC) data, average urban unemployment rates during the 1980s and 1990s exceeded 8 percent in all countries analyzed in this book except for Brazil. Unemployment comparisons should be treated cautiously because they are not strictly comparable. For instance, in the Caribbean countries the unemployment rates include discouraged workers (those who drop out of the labor force), while such workers are excluded in the Latin American countries, which compute unemployment rates according to more traditional definitions.<sup>3</sup> Many have remarked that the high level of regulation of economic activity in the region accounts for problems in the labor markets in the region, and the essays assembled here shed light on this conjecture.

### **I.3 Labor Market Regulations and Institutions in Latin America and the Caribbean**

This section sketches the history of labor market regulation in the region and describes and quantifies the regulatory environment in Latin America and the Caribbean. It compares the level of regulation and pace of regulatory reform in LAC countries and OECD countries. When it is credible to do so, we also make an effort to quantify the monetary costs (as a percentage of wages) of full compliance with regulations without discussing whether costs are borne by workers or firms. We discuss this issue more extensively in sections I.4 and I.5.

#### **I.3.1 Regulations Governing Individual Contracts**

Throughout Latin America, labor codes determine the types of contracts, the lengths of trial periods, and the conditions of part-time work.

3. That is, they only include persons who are available for work and who are taking specific steps to search for a job.

Regulations favor full-time, indefinite contracts over part-time, fixed-term or temporary contracts. As a form of worker protection, labor codes mandate a minimum advance notice period prior to termination, specify which causes are considered justified causes for dismissal, and establish compensation to be awarded to workers depending on the reason for the termination. In contrast, temporary contracts can be terminated at no cost, provided that the duration of the contract has expired. To prevent firms from exclusively hiring workers under temporary contracts, in most countries the use of such arrangements is severely restricted. Labor codes also limit trial periods—that is, the period of time during which a firm can test and dismiss a worker at no cost if his or her performance is considered unsatisfactory.

Although most OECD countries began regulating their labor markets when they had attained relatively high income per capita, Latin America and other developing countries started regulating their markets much earlier in the development process (Lindauer 1999). The first regulations date from the beginning of the twentieth century. The motivation for these regulations was the perceived need to protect the welfare of workers against the excessive power of employers, and to insure workers against the risk of job loss and income insecurity (Lindauer 1999). The Mexican Constitution of 1917 articulated the principle that protecting workers was one of the duties of the state. By the 1930s and 1940s, most countries had a labor code. The belief that each new reform should only strengthen the set of warranties and benefits awarded from previous laws became widespread. For many years, successive reforms expanded the protection that the law afforded to workers. There was little examination of the question of whether such regulations would affect economic performance. However, until the 1980s most countries in the LAC region were isolated and their industries heavily protected. Labor regulations were one way of distributing the rents from protection among covered workers and employers. Regulations are a low-cost way (from the point of government fiscal authorities) of providing social insurance to protect workers. The weak fiscal systems in place in the region together with the low level of income, and a tradition of tax evasion, corruption, and noncompliance made the social insurance schemes used in more developed countries prohibitively costly.

Military rule often led to deregulation of labor markets. Unions were frequent targets, as much for political as for economic reasons. The political and economic environment in LAC changed substantially in the 1980s and 1990s. Most countries restored democracy after long periods of military rule. These political changes bred some labor reforms—first, to restore union activity, which had been made illegal in many military regimes and, second, to reach a new social pact. In Chile, Brazil, and the Dominican Republic, at the beginning of the 1990s and later in Nicaragua in 1996, these reforms produced more protective labor regulations.

A new constitution was enacted in 1988 in Brazil as part of the process of redemocratization during the second half of the 1980s (see Barros and Corseuil, chap. 5 in this volume). This new constitution revised labor regulations that had been in place since the 1940s. The new constitution reduced the maximum working hours per week from forty-eight to forty-four hours; reduced the maximum number of hours for a continuous work shift from eight to six hours; increased the minimum overtime premium from 20 percent to 50 percent; increased maternity leave from three to four months; and increased the value of paid vacations from 1/3 to at least 4/3 of the normal monthly wage. The new constitution also modified the mandatory individual saving accounts system created in 1966. Prior to the reforms, the law required employers to deposit 8 percent of employees' wages into a worker-owned account. In case of a firm-initiated separation, workers could withdraw the accumulated funds (plus the interest rate). In addition, if a firm initiated a separation, it had to pay a penalty equivalent to 10 percent of the amount accumulated in the account. As part of the 1988 reform, this penalty was increased to 40 percent, considerably increasing the cost of dismissing a worker.

In the case of Chile, the 1990 reform introduced with the return to democracy reestablished some of the protection to workers that had been eliminated during the military regime. Under the dictatorship, union activity had been severely restricted and some benefits, such as indemnities for dismissal, had been substantially reduced.<sup>4</sup> In 1990, the new law increased maximum indemnities from five to eleven months of pay. It also reintroduced the need for firms to prove just cause for dismissal, although unlike the case in other countries, the new law considered the economic needs of the firm a just cause.

While in some countries lawmakers were busy increasing legal protection for workers, the economic environment was changing substantially. The deep economic crisis that ensued with the debt crisis of the early 1980s called into question the protectionist model. The relatively good performance of the Chilean economy, which in the mid-1970s opened to trade and introduced many promarket reforms, spawned imitators all across Latin America. By the second half of the 1980s and the early 1990s, most countries had drastically reduced tariffs on imports. The new openness to international trade increased the demand for labor market flexibility. It was argued that without sweeping labor market reforms, Latin American economies would not be able to compete internationally. This was the main motivation behind the reforms that introduced temporary contracts in Argentina, Colombia, Ecuador, Nicaragua, and Peru and that reduced the cost of dismissing workers with indefinite contracts in Colombia (1990)

4. See Montenegro and Pagés, chap. 7 in this volume.

and Peru (1991). Temporary and fixed-term contracts were introduced in Argentina in 1991, and their role was expanded in 1995 (see Hopenhayn, chap. 9 in this volume). These changes were influenced by similar reforms in Spain during the 1980s. Special fixed-term duration employment promotion contracts could be awarded to unemployed workers and to workers younger than twenty-five and older than forty years old. For some types of contracts, severance pay was reduced by 100 percent. However, these contracts were eliminated in 1998, when the share of persons working under these arrangements had increased substantially. Ecuador, Peru, and Colombia also lifted restrictions on the use of these types of programs in the early 1990s. In Peru, the number of workers hired under these contracts increased enormously. In Brazil, the use of such contracts has been liberalized since 1998.

The 1991 reforms in Peru reduced the cost of dismissing workers hired under indefinite contracts. During 1971–1991, workers who had completed trial periods were granted permanent job security. If a firm dismissed a worker and could not prove just cause in labor courts, the worker could choose between being reinstated in his or her job or receiving a severance payment of three months' wages per year of work (with a maximum of twelve months pay). In practice, because workers could always ask to be reinstated and then settle for a higher severance pay, the mandatory amount was a lower bound of the firing cost. See Saavedra and Torero (chap. 2 in this volume).

Beginning in 1991, workers hired after that year could be dismissed at will upon payment of a severance benefit. In addition, just cause clauses were extended to allow the dismissal of workers who did not perform up to expectations. The severance pay schedule was reduced from three months' wages to one month's wage for every year of tenure for workers with more than one year in the firm, with a minimum of three months' wages and a maximum of twelve. The 1993 constitution replaced the right of workers to a permanent job with the right of firms to dismiss workers. In July 1995, a second wave of labor reforms simplified the severance payment to one month per year of work, up to a maximum of twelve months, and the two-tier severance system was eliminated. These modifications substantially reduced the cost of dismissing workers. However, in November 1996 the severance payments rule was increased again to one and one-half months' wages per year of work, with an unaltered maximum cap of twelve wages.

In Colombia, the 1990 labor reforms liberalized many aspects of labor regulation. Besides regulations introducing the use of temporary contracts, the most important changes were those in the *Cesantias*, or severance pay that firms owed to workers at the end of the work relationship, regardless of the cause or the party that initiated separation. Prior to the reforms, employers were mandated to pay severance of one month per year at the time of the separation based on the salary at the separation. Work-

ers could obtain advanced payments against their benefits. Such withdrawals were credited against the severance pay due to workers at the end of the labor relationship in nominal terms as of the date of the withdrawal. High rates of inflation increased the costs of such schemes to employers. After the reform, the withdrawals were credited in real terms, substantially reducing costs for firms. In addition, the reforms eliminated the right to reinstatement for workers with more than ten years of tenure. Offsetting these cost-reducing features, the reforms increased the cost of indemnities for dismissal.

Panama (1995) and Venezuela (1997) also undertook labor reforms with the goal of increasing labor market flexibility while preserving some form of protection to workers. In both countries, reforms increased mandatory pay in case of separation but considerably reduced the additional amount that firms had to pay in case of a firm-initiated dismissal.

In contrast to Latin American regulation, in the Caribbean a mixture of legislation, common law doctrines, custom, and policy characterizes the institutional context. At the beginning of the twentieth century, in all countries of that region, regulation of the labor market was based on common law rather than on the civil law tradition predominant in Latin America (see Downes, Mamingi, and Antoine, chap. 10 in this volume). While in some countries, like Barbados, most aspects of labor relation are still left to the courts to determine; in others, such as in Trinidad and Tobago, the enactment of different regulations has progressively increased the level of statutory protection to workers. In Barbados (1973), Trinidad and Tobago (1974), and Jamaica (1985), labor reforms instituted mandatory severance pay, although, as shown in the next section, at levels that are much lower than those prevalent in Latin America.

### 1.3.2 Payroll Contributions and Other Mandatory Benefits

As in most industrial countries, in LAC many social protection programs, such as old-age pensions, public health systems, unemployment subsidies, and family allowances are funded from payroll contributions. In addition, regulations mandate other employee-paid benefits such as occupational health and safety provisions, maternity and sick leave, overtime pay, and vacations.

Unlike changes in labor codes that tend to be infrequent events, changes in the level of contributions to these programs occur often. In addition, during the 1990s, many countries implemented reforms, which transformed pay-as-you-go systems into full or partial capitalization systems. One of the advantages of such schemes is that they tend to increase the link between contributions and benefits. However, at the same time, many countries, most noticeably Colombia, El Salvador, Mexico, Uruguay, and Brazil, increased the level of payroll taxes to reduce the actuarial imbalances present in their social security systems. Below, we quantify the levels

and changes in these contributions across Latin America and OECD countries.

### I.3.3 Collective Bargaining

Unions in Latin America tend to be firm- or sector-based and weak. In most cases, the state intervenes in union registration and accreditation as well as in the process of collective bargaining. The state authorizes only certain unions to have representation authority (Argentina, Mexico, Peru, and Brazil), and intervenes in the resolution of conflicts and the arbitration process (Argentina and Mexico). Only in Brazil and Argentina is collective bargaining highly centralized at the sector level, while in Nicaragua and Colombia, sector-level bargaining coexists with firm-based negotiation. In Mexico, collective bargaining takes place at the firm level, but a high level of centralization is achieved through a strong corporatist structure and through union discipline (O'Connell 1999). In contrast, unions are stronger, and collective bargaining tends to be national or sector-based in OECD countries, with the exception of Canada, New Zealand, the United Kingdom, and the United States.

According to data from ILO (1997–1998), union density as a percentage of nonagricultural employment is higher in Brazil, Mexico, Argentina, and Nicaragua and smaller in the rest of the Latin American countries. Union affiliation tends to be higher in countries where collective bargaining is more centralized. Overall, union density is lower in Latin America (14.7) than in industrial countries (36.6).<sup>5</sup> There are also large differences in coverage rates. Thus, while collective bargaining agreements in countries such as Spain, France, and Greece, which are negotiated by a minority, are extended to almost all employees, in Latin American countries this is generally not the case. As a result, coverage rates in Latin America tend to be much lower than those observed in OECD countries with similar affiliation rates.

The influence that collective bargaining exerts on wage and employment conditions, measured by affiliation rates, is declining over time. Thus, LAC countries share a trend that has been well documented for OECD countries. Affiliation rates have declined in all of the countries of the region.<sup>6</sup> This decline has been especially large in Mexico, Argentina, Venezuela, Costa Rica, and Uruguay. In this volume, we only present estimates for Uruguay on the impact of unionization on employment. Cassoni, Allen,

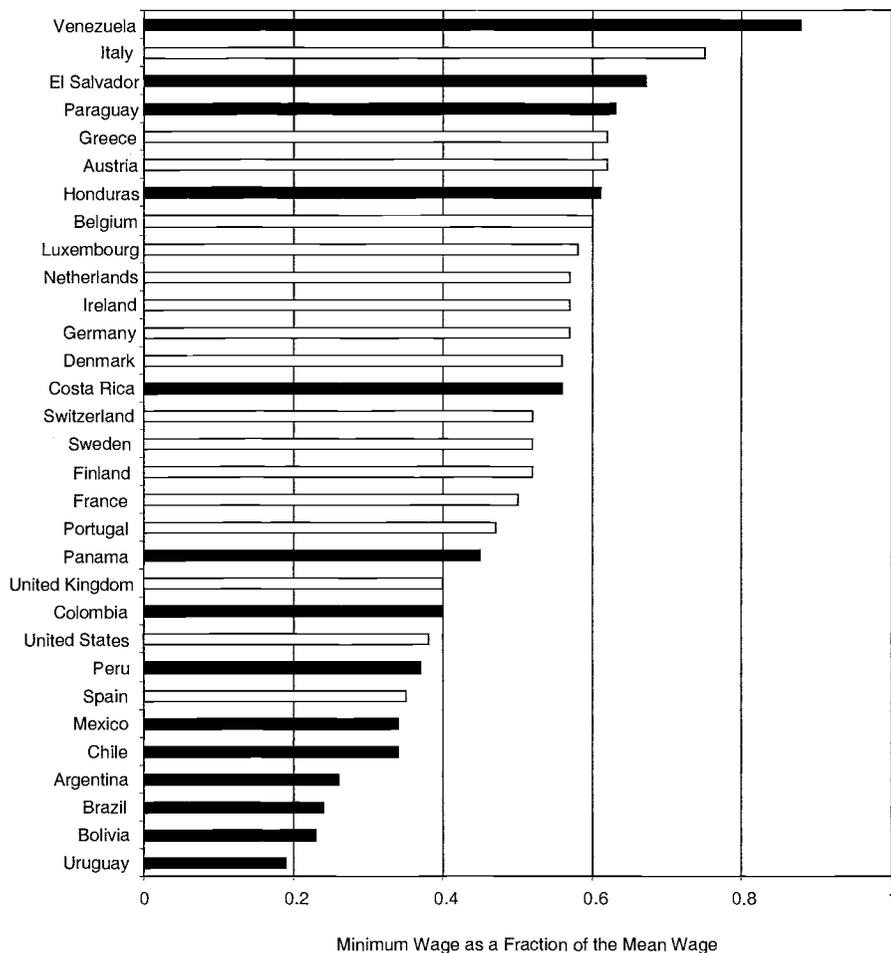

5. ILO data corresponds to the mid-1990s. The comparison between LAC and industrial countries reflects the difference between unweighted regional averages. The average for industrial countries includes the following countries: France, Spain, United States, Greece, Germany, Italy, United Kingdom, Denmark, Belgium, Finland, Iceland, Ireland, Sweden, and Canada.

6. The ILO data for 1985 and 1993 indicates that union affiliation increased in Chile during that period. Yet, data from a later period indicates that union affiliation has been declining since 1993.

and Labadie (chap. 8 in this volume) estimate a strong adverse impact of unionism on employment in Uruguay. The evidence for other Latin American countries is still too sparse.

### I.3.4 Minimum Wages

Minimum wages are widely used in Latin America to increase the wages of the poorest workers. Figure 2 (taken from Maloney and Nuñez Mendez,

**Fig. 2 Minimum wage/mean wage in OECD countries and in Latin America**

*Source:* Maloney and Nuñez Mendez (chap. 1 in this volume).

*Notes:* Minimum wages from Dolado et al. (1996), for one year within the range 1991 and 1995. Minimum wages for Latin America are from 1995 or 1996, except Argentina (1998), Bolivia (1997), Brazil (1998), Colombia (1998), Honduras (1999), Mexico (1999), and Uruguay (1998).

chap. 1 in this volume) ranks various Latin American and OECD countries by their minimum wage, standardized by the mean wage.<sup>7</sup> While some Latin American countries appear in the lower range of this distribution—most notably Uruguay, Bolivia, Brazil, Argentina, Chile and Mexico—others, such as Venezuela, El Salvador, Paraguay, and Honduras, have very high minimum to average minimum wages by OECD standards. These high levels suggest that minimum wages are likely to be binding, and, as a result, to reduce employment and to retard downward wage movements in the presence of adverse demand shocks.

Data on enforcement of the minimum wage is incomplete. However, some evidence available for workers between twenty-five and forty years old suggests that about 10 percent of wage employees in that age range earn salaries below the minimum wage (see table 2). In some countries, such as Mexico, Uruguay, Bolivia, and Argentina, the proportion below the minimum in this age range is very small. In other countries, such as Colombia, minimum to average wages are high but a large proportion of the labor force in the twenty-five to forty age range earns wages below the statutory minimum. Whether the adverse effect of a high level of minimum wages is offset by substantial noncompliance remains an open empirical question.

### I.3.5 What Motivates Reforms?

In studying the effect of reforms in the labor market it is important to examine what factors initiate these relatively infrequent episodes. It could be argued that labor market outcomes are driven by the same events that drive the reforms and not by the labor reforms themselves. Panels A–F of figure 3 (for Latin America) and panels G–I of figure 3 (for the Caribbean) plot GDP growth rates and unemployment rates for the countries covered in the individual country studies of this volume during the period 1980–2000. They also plot major episodes of labor reform (marked with a continuous line if a liberalization of the labor market occurred and a dotted line if the reforms increased protection to workers).<sup>8</sup> In addition, these figures mark episodes of major tariff reductions (double line) or the end of military regimes and the return to democracy (discontinuous line).

In Argentina, Colombia, Peru, and Uruguay, reforms that liberalized the labor market occurred within one or two years before or after major reductions in tariffs and were part of efforts to liberalize economies and increase the participation of the market in the production and allocation of goods and services. In Chile and Brazil, reforms that increased the legal

7. The observations are from the early 1990s for the OECD countries and from the mid- and late 1990s for LAC. Data from OECD were obtained from Dolado et al. (1996), data from LAC comes from IADB (1998–1999) and Maloney and Nuñez Mendez (chap. 1 in this volume).

8. Only major changes in labor codes or other major government interventions in the labor market are included. Changes in social security contributions or payroll taxes, as well as changes in the level of minimum wages—which occur quite frequently—are not included.

**Table 2** Compliance with Regulations

Country	% of Workers with Mandatory Social Security Programs		% of Workers 25–40 Years Old with Net Earnings Below Minimum Wage
	% of Total Employment (Mean 1990s)	% of Wage Employment (Mean 1990s)	Noncompliance with Minimum Wages (End 1990s)
Average Latin America <sup>a</sup>	42.76	60.05	10.06
Argentina	48.45	66.56	3.11
Bolivia (1999)	26.36	38.56	1.11
Brazil	48.18	64.04	5.80
Chile	64.47	77.45	7.3
Colombia (1999)	46.13	66.77	26.9

*Source:* IADB (2004), based on individual country household surveys.

*Notes:* Percentage of workers between fifteen and sixty-four that are affiliated to social security. Time series data for the 1990s is incomplete; the mean was computed when data included three or more years, spread over three periods: early (1990–1993), mid (1994–1997), and late (1998–2001). Noncompliance with minimum wage refers to employees between twenty-five and forty years old working more than thirty hours. Figures for this variable date from the late nineties. N.a. denotes not available.

<sup>a</sup>Unweighted average.

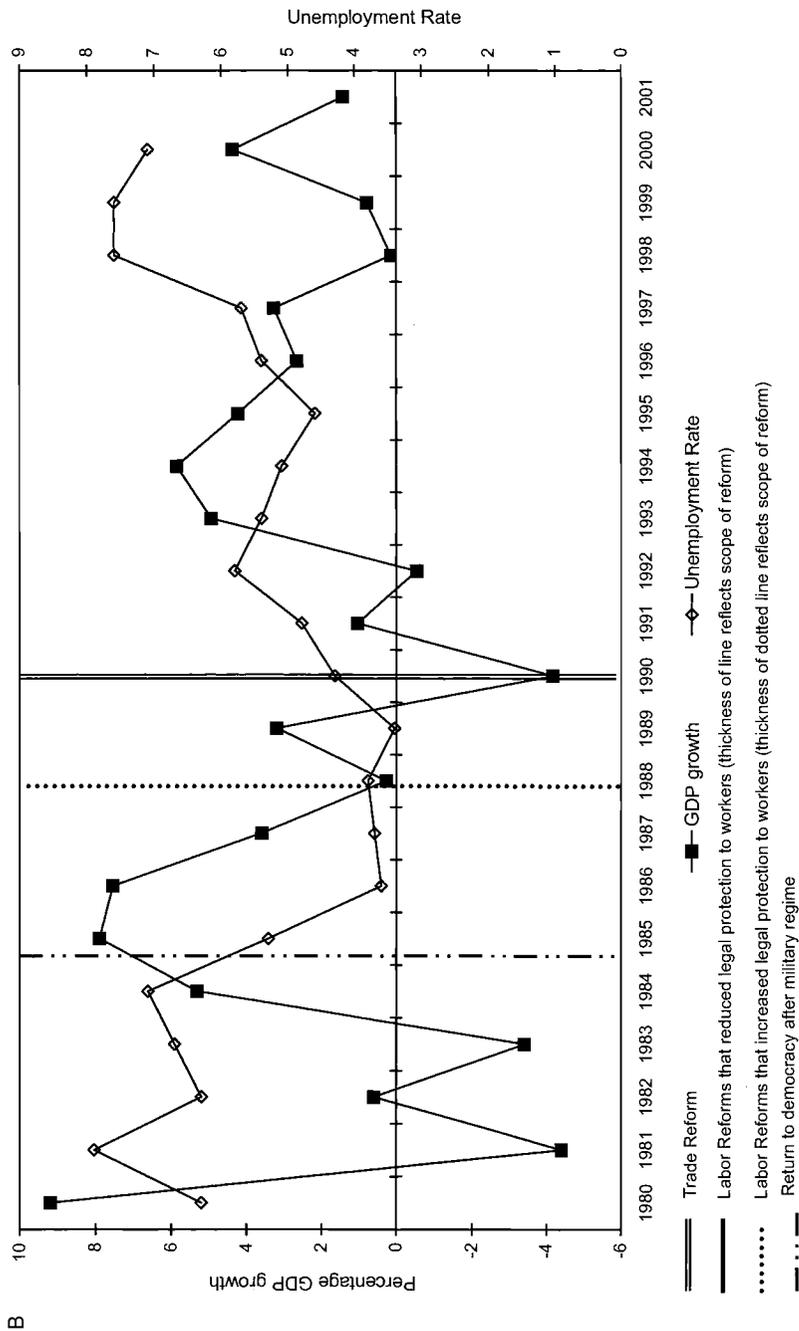

protection of workers occurred in the context of a transition to democracy. In all of these episodes it could be argued that labor reforms were exogenous to the economic system because they were driven either by a new economic philosophy or by profound transformations in political regimes, although one could counter that these political transitions were facilitated by economic developments. Some reforms and transformations are clearly driven by changes in economic activity. There is evidence that many reforms tend to occur around periods of negative economic growth. In the countries and periods analyzed in this volume, there have been at least fifteen episodes of reform. Out of these fifteen, six episodes of reform occurred in years in which GDP had declined the year before. However, four of those reforms increased the legal protection to workers, and two liberalized the labor market.

Overall, there is no empirical relationship between labor reforms and labor market outcomes driven by economic performance. Our cross-country

time series analysis presented in this chapter controls for present and past levels of economic activity to account for the possibility of endogeneity. The disaggregated studies use year effects and other strategies to control for endogeneity.

### I.3.6 Quantifying the Cost of Regulation

This section constructs measures of labor laws that can be compared across countries and time (see also Heckman and Pagés 2000). Many studies that summarize institutional data across countries construct qualitative indices that rank variables across countries. For instance, Grubb and Wells (1993) construct a series of indicators of employment protection by ranking different aspects of job protection across countries and averaging these different rankings in one summary indicator. Although such measures summarize many complex institutional features, they are not comparable over time. A second group of studies constructs measures that aggregate institutional aspects of the labor market by assigning to each country and year a value in a certain range, for instance, between zero and one. These measures summarize a large number of interesting aspects and are comparable across time. However, they can also be quite arbitrary because it is difficult to justify any assigned numerical values for qualitative variables, and because it is difficult to compare one measure against another. Moreover, the measures are very sensitive to the weights assigned to the different components of these measures. From a policy standpoint, summarizing many features of a regulatory system in one indicator makes it impossible to distinguish which components, if any, have an adverse effect on employment.

We take a different route by constructing measures of the direct cost (measured as a fraction of average monthly wages) of complying with labor laws. These measures can be compared not only across countries and over time, but they can also be compared against each other. This allows us to quantify, for instance, the share of the total costs given by each type of regulation. Our measure of mandatory total costs (TC) of regulations is

$$TC = SSP + JS.$$

It is the sum of the cost of social security payments (SSP) plus the cost of abiding by job security provisions (JS). These costs are expressed as fractions of the average monthly wage.

This measure of the cost of regulation omits some important components of labor cost. For example, the costs of abiding by certain laws are hard to quantify and are omitted. One example of laws whose costs are difficult to quantify is the prohibition against dismissing workers in bad times. In addition, this measure does not include the cost of regulating the length of the standard workweek and overtime work. It does not include the cost of complying with minimum wage laws or other income floors. We do not include regulations on temporary labor contracts. Although these

regulations are likely to have effects on employment and unemployment, we choose to exclude them because comparable data on the share of the labor force affected by these regulations across time and countries are difficult to obtain. We leave the quantification of these features of regulations for future work.

There is one major conceptual problem with this index. It does not distinguish between static and dynamic aspects of the cost of labor. Job security affects both components of costs by raising the total cost of labor and by increasing the cost of adjusting labor. Social security costs affect the unit cost of labor without affecting dynamic costs of labor. Our index of total cost is not a measure of the price of labor facing firms at different stages of the business cycle. We develop this point below and in appendix B.

### *Quantifying Job Security Provisions*

Our index includes, in job security legislation, those provisions of the law that increase the cost of dismissing a worker for economic reasons.<sup>9</sup> Across countries, termination laws require firms to incur at least five types of costs: administrative procedures, advance notification, indemnities for dismissal, seniority pay, and the legal costs of a trial if workers contest dismissals. Administrative procedures require the firm to notify and seek approval by labor unions or the Ministry of Labor to extend the period between layoff decisions and the actual occurrence of layoffs. They may also involve long negotiations to place workers in alternative jobs. The period of advance notification should also be included in the computation of labor costs because in many countries, laws allow firms to choose between providing advance notice or paying a compensation equivalent to the wages for the corresponding period. Moreover, since productivity declines substantially after notice, advance notification should be considered as a part of dismissal costs even when firms choose to notify workers in advance. Therefore, we assume that employees do not work at full productivity levels after notification.<sup>10</sup> In most countries, mandatory advance notice periods increase with tenure, and in others they are higher for white-collar than for blue-collar workers.

Most Latin American and OECD countries mandate indemnities in cases of firm-initiated dismissal. In general, indemnities are based on multiples of the most recent wage and the years of service. Some countries calculate the amount of mandatory indemnities based on whether the dismissal is deemed just or unjust or whether the worker is blue collar or white

9. In most countries, the law does not mandate compensation for dismissal if the separation is due to employees' misdemeanors. However, if such behavior cannot be proved, the worker has to be compensated at the regular legal rate.

10. There is some evidence that advance notice stimulates on-the-job search during the notification period (Addison and Portugal 1992), which suggests a reduction in the effort devoted to work.

collar. In contrast, seniority pay is only mandated in a few Latin American countries in which the law requires employers to make a payment upon termination of the work relationship, regardless of the cause or party initiating the separation. In these countries, firms initiating dismissal are required to pay both indemnities *and* seniority pay. In some countries, this payment is deposited as a regular contribution to the worker's individual savings account. In these countries, workers can withdraw principal and interest from their account upon separation. In other countries, seniority pay is determined as a given amount that has to be paid to the worker upon termination of the work relationship.<sup>11</sup> Finally, firms can incur considerable additional costs if workers contest dismissal in courts. If judges rule in favor of workers, firms not only have to pay indemnities, but also the workers' foregone wages during trial.

To compute the monetary cost of labor laws, we improve on the job security measures developed in Heckman and Pagés (2000) in three ways. First, we expand our previous database to include the 1980s in all OECD countries. This expansion of the data set allows us to capture some additional labor reforms in OECD countries not previously captured. Second, we revise and correct some of our previous data on advance notice and indemnities for a number of countries to better capture the actual cost of the law (see appendix A for a complete description of the methodology and assumptions involved). Finally, we include the cost of seniority pay in our measure of job security, which we did not include in our previous work.

Our measure of the cost of job security,  $JS_{jt}$ , for country  $j$  at time  $t$  is constructed from the following formula:

$$\begin{aligned}
 (1) \quad JS_{jt} &= \sum_{i=1}^T \beta^i \delta^{i-1} (1 - \delta) (b_{j,t+i}) \\
 &\quad + \sum_{i=1}^T \beta^i \delta^{i-1} (1 - \delta) [a_j \cdot y_{j,t+i}^{jc} + (1 - a_j) \cdot y_{j,t+i}^{uc}] + \sum_{i=0}^T \beta^i c_{j,t+i} \\
 &= AN_{j,t} + ID_{j,t} + SenP_{j,t},
 \end{aligned}$$

where  $\delta$  is the probability of a worker remaining in a job in a period,  $\beta$  is the discount factor,  $i$  denotes tenure at the firm, and  $T$  is the maximum tenure that a worker can attain in a firm, which is assumed to be twenty years ( $T = 20$ ). The expression is broken down into three terms corresponding to advanced notice costs ( $AN_{j,t}$ ), indemnity costs ( $ID_{j,t}$ ), and seniority pay ( $SenP_{j,t}$ ). The first term in expression (1) is the discounted cost of future advance notice, weighted by the probability that a worker will be dismissed, after one, two, three, and so on periods at the firm, where  $b_{j,t+i}$  is the advance notice to a worker who has been  $i$  years at a firm measured in

11. For an extensive description of job security measures, see OECD (1993, 1999) for OECD countries and IADB (1996) for Latin America.

monthly wages. The second term in expression (1) is the discounted cost of future indemnities, weighted by the probability of dismissal after  $i$  periods at the firm. In this expression,  $a_j$  denotes the probability that the economic difficulties of the firm are considered a just cause of dismissal, while  $y_{j,t+i}^{jc}$  ( $y_{j,t+i}^{uc}$ ) is the mandated indemnity in case of just cause (unjust cause) dismissal, again measured in monthly wages. Finally, the third term in expression (1) captures the cost of seniority pay, and  $c_{j,t+i}$  denotes contributions to a worker's savings account measured in monthly wages.<sup>12</sup> We assume a common discount and dismissal rate of 8 and 12 percent, respectively, across countries. The choice of the discount rate is based on the historical returns of an internationally diversified portfolio. Our choice of the turnover rate is motivated by the concern that turnover rates are affected by the legislation in countries with job security provisions and by the lack of the turnover data for most countries of the sample. We use a benchmark turnover rate from the United States, a country with lower job security costs than any country in our LAC sample. Evidence on turnover rates for Latin America is scant. However, evidence for a few countries for which job reallocation rates can be computed suggest that turnover rates in Latin America are within the ranges observed in the United States and other developed countries (Inter-American Development Bank [IADB] 2004). The choice of this benchmark is clearly a rough way to avoid endogeneity problems. To assign values to the discounted future payments of advance notice, indemnities and seniority pay, we use the information contained in tables A.1 and A.2 in appendix A. When regulations mandate different provisions for white-collar and blue-collar workers, we take the unweighted average for the two types of workers.

By construction, our job security measures give a higher weight to dismissal costs that may arise soon after a worker is hired because they are discounted less at the time of hiring, while they discount more firing costs that arise further in the future. Our measure captures the expected average cost. Consequently, it does not measure the true marginal labor cost, which is state contingent, nor does it distinguish dynamic from static costs, as we have previously noted. We discuss these issues further in appendix B.

### *Quantifying the Cost of Social Security*

To quantify the cost of social security regulations and payroll taxation, we gather data on mandatory payroll contributions to old age, disability and death, sickness and maternity, work injury, unemployment insurance, and family allowances programs. Because the nominal incidence of the contributions (whether they fall on the employer or the employee) is irrel-

12. In two countries, the law mandates seniority pay, but this is not capitalized in individual savings accounts. See appendix A for a description of this case.

evant in measuring total social cost (although it is not irrelevant for the study of labor demand), we add both contributions as a percentage of wages. To quantify the cost of social security provisions in a way that is comparable to the cost of job security, we compute the expected cost of social security provisions (SSP) at the time of hiring as

$$SSP_{jt} = \sum_{i=0}^T \beta^i (ss_{j,t+i}^e + ss_{j,t+i}^w),$$

where  $ss_{j,t+i}^e$  and  $ss_{j,t+i}^w$  are, respectively, the costs of payroll taxes paid by the employer and the worker expressed as a percent of wages, and  $\beta$  is the discount rate.<sup>13</sup>

### 1.3.7 The Cost of Labor Laws across Countries

Table 3 summarizes our measures of the cost associated with different labor regulation regimes. In the first three columns, we summarize the cost of abiding by employment protection laws at the end of the 1990s. We generate these indices for all countries in all years for which we have data. Table 3 only reports those values for the last year of our sample. Column (1) summarizes the cost of giving advance notice to workers. In the Latin American countries, the typical required advance notice is a month or the equivalent to 0.63 monthly wages in expected value terms. Bolivia stands out as the country that requires one of the longer advance notice periods (1.77 months in expected terms), while Peru and Uruguay require no advance notice. Mandatory advance notice provisions tend to be more stringent in OECD countries. Many OECD countries mandate fairly long advance notice periods, particularly for skilled workers. In addition, in most countries, advance notice periods increase with seniority. In Belgium, for instance, the mandatory advance notice for skilled workers with ten years of seniority is nine months, while for workers with twenty years of seniority it is fifteen months. In Sweden, all workers with ten years of seniority are entitled to an advance notice period of five months, whereas for a worker with twenty years of seniority, the mandatory advance notice period is six months. The fact that Belgium and Sweden have very similar values in table 3 reflects the fact that in Belgium very high advance notice only applies to skilled workers, whereas in Sweden it applies to all workers. It also reflects the fact that our measure heavily discounts costs that are expected to occur far in the future. On average, mandated advance notice periods are significantly longer in OECD countries than in the LAC sample.

The second column displays the cost of indemnities for dismissal. Within the LAC sample, Colombia, Peru, Ecuador, Bolivia, El Salvador, and

13. We obtain the information on these contributions from the series *Social Security Programs Throughout the World*, edited by the United States Social Security Administration (1983–1999).

Note: EPV denotes Expected Present Discounted Value. Dashes indicate missing value.

Honduras stand out as countries where the cost of abiding by these regulations is the highest. In the sample of OECD countries, Portugal, Turkey, Korea, Italy, and Spain are the ones where indemnities for dismissal laws are more costly (in terms of expected monthly wages), while a number of countries, including Belgium, Finland, Germany, Japan, Netherlands, New Zealand, Norway, Poland, Sweden, Switzerland, and the United States do not mandate indemnities for dismissal. Comparing the two regional samples, it is clear that, on average, compensation for dismissal is three times larger in LAC than in the OECD countries, despite the much lower level of income in the LAC region.

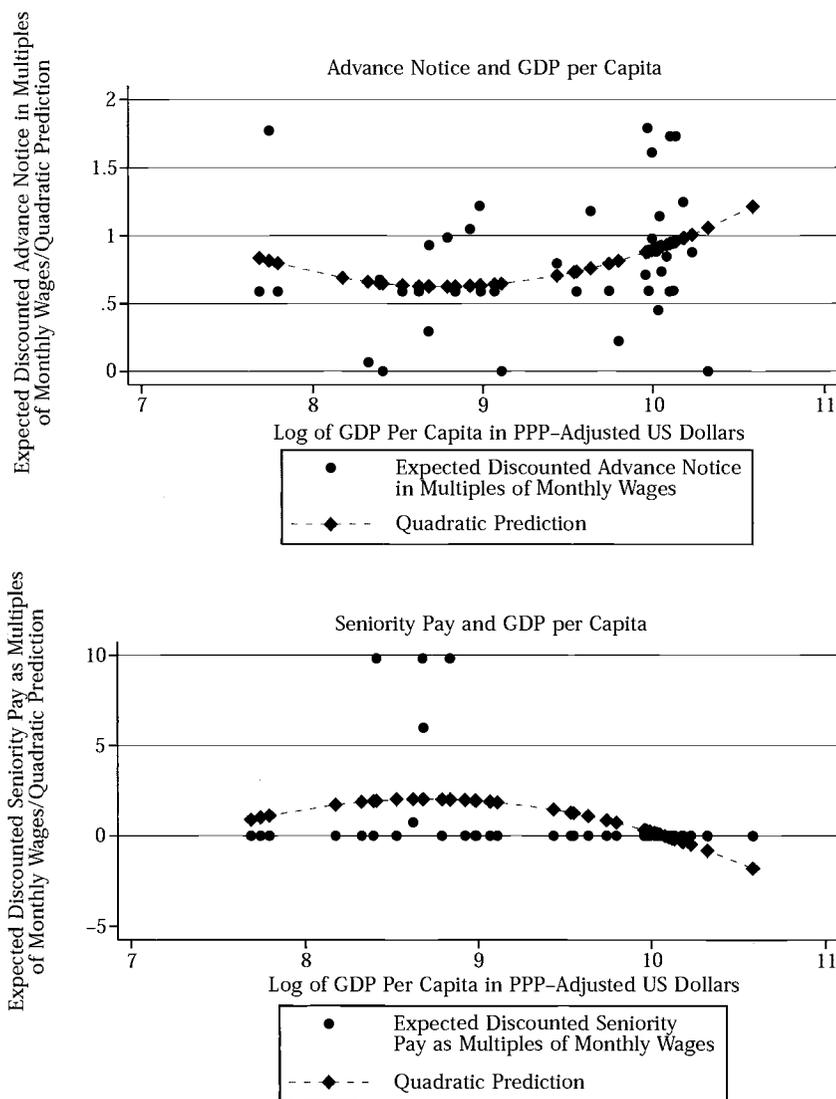

The third column refers to seniority pay. This additional payment is mandatory in only six Latin American countries, but the estimated expected discounted costs are large when this feature is present. In Colombia, Brazil, Ecuador, and Peru, employers are required to deposit about one month of pay every year to workers' individual savings accounts. Over the life of a worker, this provision is expected to cost about ten monthly wages in these four countries. Once advance notice, compensation for dismissal, and severance pay are added, we find that the cost of job security provisions is much higher in the poorer LAC region than in the richer OECD sample.

The fourth column reports the expected costs of complying with social security laws. Compared to the costs of employment security, social security costs are very large and therefore constitute the lion's share of the total costs of labor laws. In Argentina, for example, expected discounted costs of social security are 44.5 months of pay, while in many OECD countries these costs are even larger. In the average Latin American country, social security payments amount to 82 percent of the total costs of labor laws. This percentage is even larger in OECD countries where, on average, they reach 96 percent of the total regulatory costs.

Once all the costs are aggregated, labor laws impose a much larger cost in OECD countries. However, the composition of these costs is quite different. While the typical Latin American country mandates shorter advance notice periods and lower social security contributions than the average OECD country, job security provisions are substantially higher in LAC.

Latin American and Caribbean countries have a higher burden of regulations that affect adjustment processes in the labor market. European countries have a higher burden of payroll taxation that affects labor demand but not labor adjustment. Both regions have a much higher burden of labor costs than North America.

Exploring the relationship between income per capita and social protection across countries, it is clear that job security provisions are strategies of low-income regions. Figure 4 graphs regression relationships for each of our measures of labor cost on GDP per capita (PPP adjusted) and GDP squared. Across countries, advance notice costs tend to increase with income; seniority pay and indemnities for dismissal decline with country in-

**Fig. 4 Labor regulations and GDP per capita**

come. Social security contributions follow an inverted U-shape pattern in income. They tend to increase with income in the Latin American sample and reach a maximum in medium-income countries, while they tend to decline with income within the sample of upper-income countries. Regulation is an inferior good. It is the response of poor countries to the demand for worker security. By imposing a mandate on firms, central governments

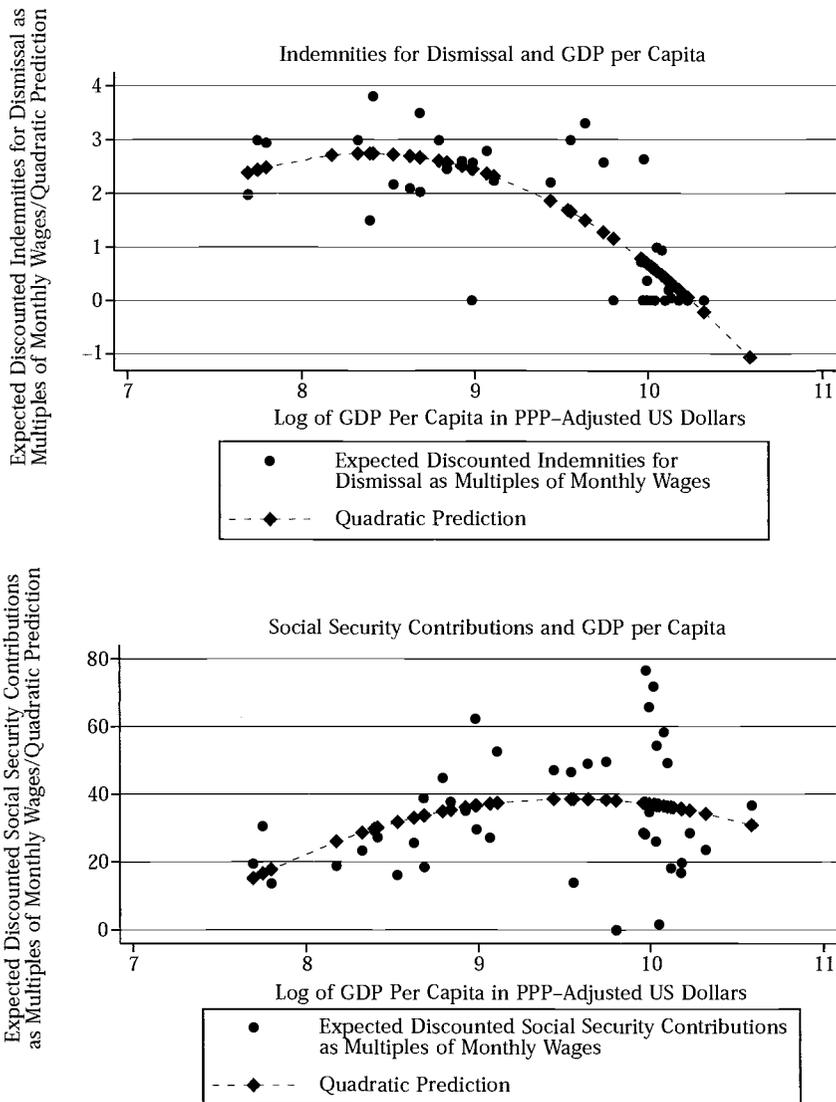

Fig. 4 (cont.)

avoid the direct fiscal cost of financing social safety nets, albeit at the cost of affecting their labor market performance.

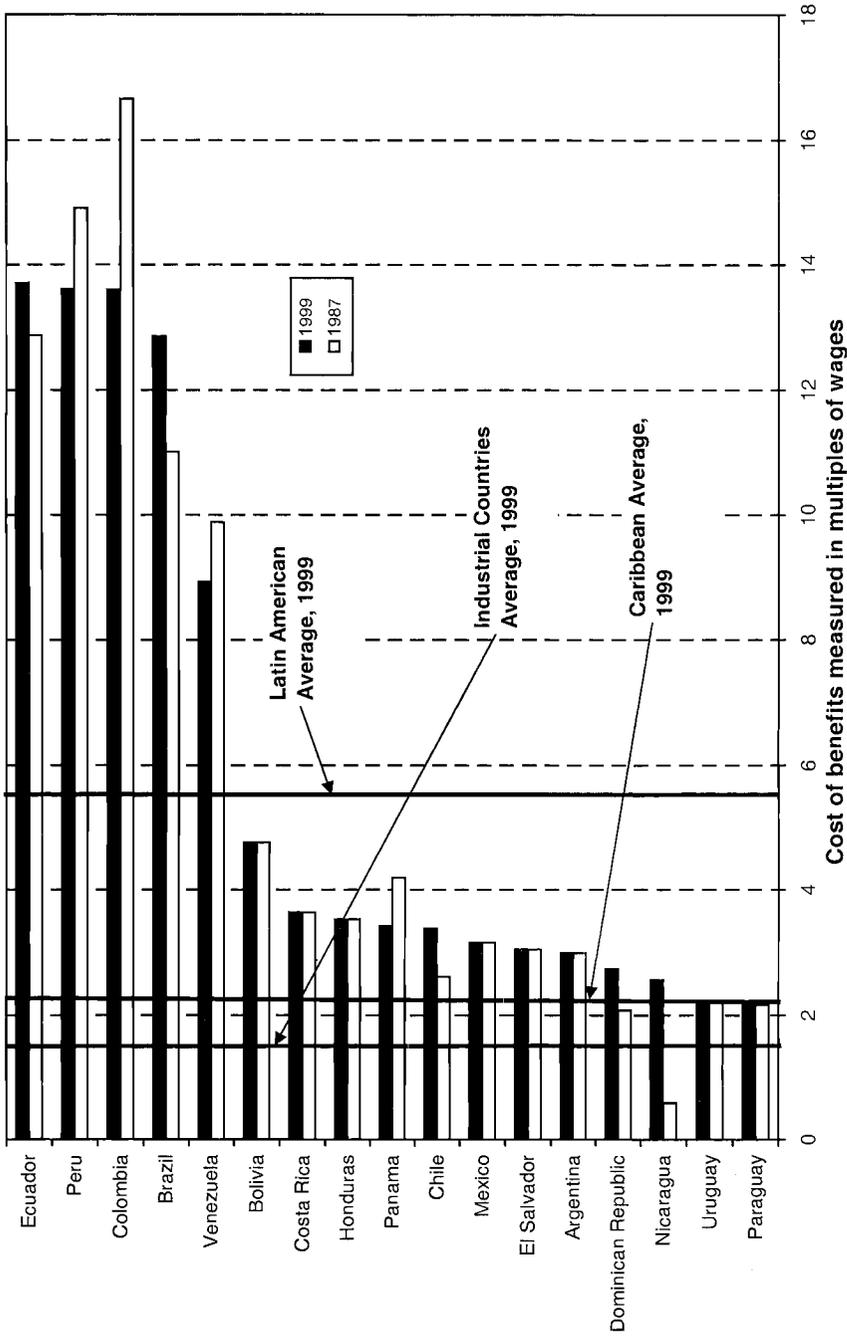

We next examine the evolution of these measures over time. Since the early 1980s there have been few reforms in job security provisions in Latin America and even fewer in OECD countries. Social security contributions have changed more, but even they seldom change drastically. This lack of variability, particularly in job security provisions, poses a challenge for em-

pirical studies of the impact of regulations. Figure 5 shows the level and the changes in job security since the late 1980s across Latin American countries. The general view that there have been important reductions in dismissal costs in Latin America is not accurate once we aggregate across all components of job security. Only Colombia, Panama, Peru, and Venezuela have experienced a reduction in the costs of terminating indefinite contracts. In Venezuela and Panama, the reduction in indemnities has been partly offset by increases in the costs of severance pay. Our measures reveal that Brazil, the Dominican Republic, Chile, and Nicaragua undertook reforms that increased the cost of dismissal. Assembling Latin American and OECD events, there are thirteen episodes in which job security provisions were changed. Nine of these episodes occurred in Latin America, and four occurred in the OECD sample. Figure 6 shows the percentage change in advance notice and indemnities for dismissal in the countries that have experienced reforms. It makes clear that changes in job security costs have been substantial in Latin America relative to the OECD sample. The enormous variation in the Latin American region and the exogeneity of some of the reforms is the reason why we think that the study of Latin American labor markets can inform further analyses of the impacts of regulation in economies around the world.

Figure 7 reports social security contributions (measured in expected discounted cost terms) at the beginning and at the end of the 1990s for Latin American countries. There have been important changes during the last decade. In many countries, social security contributions increased during the 1990s as a consequence of pension reforms and population aging. Yet, in some countries, most significantly in Argentina, social security contributions were reduced during the decade.

### 1.3.8 Enforcement and Informality

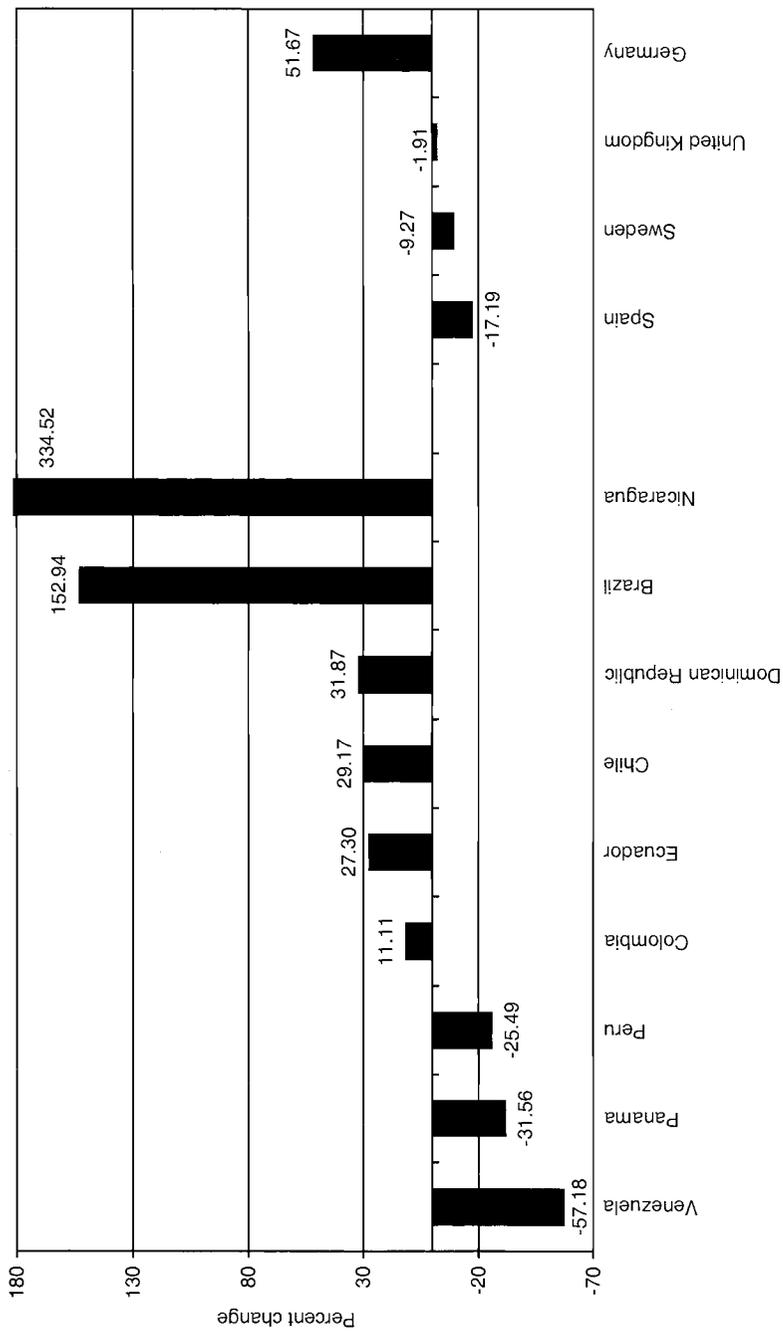

The measures summarized in table 3 calculate *de jure* cost of regulations, assuming that firms and workers abide by the text of the law. In practice, however, enforcement is at best weak, and many workers end up not being covered by mandatory regulations. Such workers are often referred to as informal workers. Given the difficulties in measuring the extent of informality, different approaches have been followed in the literature. Some authors follow the traditional ILO approach of classifying as informal those workers who are either self-employed, work for firms with five or less employees, work as unpaid family help, or are employed as domestic workers. Although some of these workers may be receiving the benefits prescribed by the law, there tends to be a high correlation between being in any of these categories of employment and not being covered by labor laws. Other authors use a more direct measure of informality, computing the percentage of workers who are affiliated with social security programs or have a formal labor contract. All authors in this volume use a “benefits” definition of

Wylie (1990)	Four 2-digit manufacturing; annual; 1900–1929; U.S.		–0.52

informality, except for the study by Maloney and Nuñez Mendez (chap. 1 in this volume), which follows the ILO convention.

Measured by the extent of compliance with social security regulations in Latin America, noncompliance is substantial. According to IADB (2004), only 42.7 percent of all workers and 60 percent of all wage employees are contributing to such programs (see table 2). Among the countries covered in the individual studies of this volume, compliance as percentage of total employment is the highest in Chile and Uruguay and the lowest in Peru. Compliance tends to be higher among skilled workers, among workers employed in larger firms, and in the manufacturing and high-paying finance and business services sectors. In these latter sectors, the effect of regulations should be easier to detect. Compliance is higher when the burden of regulation is lower.

#### **I.4 The Impact of Labor Market Regulations**

This section summarizes the studies of the impact of labor market regulations that are presented in this volume and places them in the context of the literature on more economically developed countries. We distinguish between policies that alter employment levels (generating static costs) from policies that affect employment flows (generating dynamic transition costs). The essays contained in this book present evidence on both types of policies. We also report findings on the effects of temporary contracts and minimum wages.

##### **I.4.1 A Static Labor Demand-Labor Supply Analysis**

A convenient starting point from which to assess the impact of labor market regulations on employment levels is the standard neoclassical labor demand-labor supply framework. If mandatory legislation increases labor costs, economic theory predicts that a move up the labor demand function produces a fall in employment. The slope of the labor demand schedule provides a good measure of the policy-induced change in employment when governments or trade unions set labor costs administratively. The standard theory is silent about the effects of the regulation on unemployment because it depends on whether the displaced workers drop out of the labor force or attempt to seek new jobs.

Table 4 summarizes estimates of constant-output labor demand elasticities for Latin America. As noted by Hamermesh (chap. 11 in this volume), these estimates are comparable to those estimated for other countries.<sup>14</sup> Al-

14. A more comprehensive measure of the impact of regulations on employment is given by the total elasticity, which includes the possible scale effects of an increase in regulation including the entry and exit of firms due to changes in labor costs. Unfortunately, there is very little empirical evidence in this book regarding the magnitude of the total elasticity, although studies by Hopenhayn and Rogerson (1993) and Nicoletti and Scarpetta (2003) suggest that entry and exit decisions are an important component of the response to regulation.

though labor demand studies abound, we focus on those studies that use disaggregated industry or individual firm data to infer the labor demand parameters, because models fit on such data produces more reliable estimates of underlying production parameters than models fit on data at higher levels of aggregation (Hamermesh 1993). Comparisons across types of workers indicate that labor demand elasticities are larger for blue-collar than for white-collar workers, suggesting a lower impact of regulations on the employment rates of the latter. Estimates of labor demand for Latin America tend to be somewhat lower than those obtained for other countries of the world, especially those estimated for Peru and Mexico. (See the estimates from industrial countries in the lower panel of the table.) Nonetheless, all estimates are between 0 and  $-1.5$ , and most of them cluster between  $-0.2$  and  $-0.6$ , well within the range for worldwide estimates reported by Hamermesh (1993) for output-constant labor demand elasticities.<sup>15</sup> This range of estimates implies that a 10 percent increase in labor costs will result in a sizable decline in employment, between 2 percent and 6 percent.

The preceding analysis assumes that the cost of regulations is entirely paid by employers. However, when the supply of labor is not perfectly elastic, part of the increase in labor costs will be compensated by lower wages, reducing the disemployment effect of the regulations. Alternatively, workers may not perceive the cost of regulation as a tax, because higher contributions pay for improved job benefits, which are valued. In this case, workers will be willing to pay for this benefit, reducing their wage demands. This wage offset would also contribute to lessening the impact of regulations on employment.

How likely is it that the costs of labor market regulations are shifted to workers in Latin America? Before reviewing the existing evidence, it is important to note important features of Latin American labor markets. First, high evasion implies that the relevant labor supply to the formal sector in developing countries is likely to be more elastic than in developed ones. Thus, if workers have access to similar jobs in both the formal and informal sectors, the possibilities of shifting costs to workers are lessened, resulting in a high elasticity of labor supply to formal-sector firms that comply with regulations. Second, as previously noted, in some countries minimum wages are quite high, both absolutely and in relation to the average wage, and this reduces the scope for wage shifts (see figure 2). Moreover, Maloney and Nuñez Mendez (chap. 1 in this volume) show piling up of workers at minimum wage levels, suggesting that compliance with the minimum wage is substantial even in the so-called “informal” sectors so that wage shifting will be attenuated in countries with a binding minimum

15. Hamermesh (1993) reports a range between  $-0.15$  and  $-0.75$  and an average estimate of  $-0.45$ .

wage that also affects the informal sector. Third, although most social security programs in the region are restricted to covered workers, and this tightens the link between contributions and benefits, the dismal financial condition of some social security systems and the high degree of discretion exercised by governments over the determination of benefits weaken this link. In this respect, the recent social security reforms aimed at privatizing pensions should strengthen the relationship between benefits and costs in many countries of the region.

Several empirical studies have attempted to measure the impact of mandatory benefits on employment rates. Gruber (1994) analyzes the effects of insurance for workplace injuries and mandated maternity benefits in the United States and finds that a large share of the cost is shifted to wages, with only minor disemployment effects. In contrast, Kaestner (1996) examines the effect of unemployment insurance contributions on the employment of U.S. youth and finds large disemployment effects and little wage shifting.

For developing countries, there is some evidence on the magnitude of wage shifts predating the studies collected in this volume. MacIsaac and Rama (1997) assess the fungibility of the cost of mandated benefits in Ecuador. In 1994, the year they study, Ecuador had one of the most cumbersome labor legislation regimes in Latin America. Beyond mandated contributions to social security programs, the law also mandated payment of thirteen-, fourteen-, fifteen-, and sixteen-month payments for separation at various times of the same year. MacIsaac and Rama's analysis suggests that while labor market regulations increase labor costs, part of the increase is shifted to workers in the form of lower base wages. Thus, for an average Ecuadorian worker, social security contributions and other mandated benefits amount to a large share of the base wage. However, workers whose employers comply with regulations earn on average only 18 percent more than workers at noncompliant firms. This difference is explained by a 39 percent reduction in the base earnings of workers in compliant firms. Interestingly, these reductions are not uniform across firms; they are smaller in larger firms and essentially zero in the public sector and in unionized firms.

Mondino and Montoya (chap. 6 in this volume) and Edwards and Cox-Edwards (1999) explore this topic for Argentina and Chile, respectively, by comparing wages of workers who have access to social security programs with wages of uncovered workers. In Argentina, Mondino and Montoya (chap. 6 in this volume) find that during the period 1975–1996, wages of noncovered workers were 8 percent higher than the wages of covered workers. Considering that employee-paid payroll contributions average 40 percent of the payroll, the share of contributions paid by workers is around 20 percent of total labor costs. In Chile, Edwards and Cox-Edwards (1999) find evidence of a larger wage shift. In 1994, cash wages for workers cov-

ered by mandatory pension, health, and life insurance were 14 percent lower than wages for noncovered workers. Since, in that year, social security contributions amounted to 20 percent of wages and were nominally paid by workers, their estimates suggest that about 70 percent of the cost of social security contributions were absorbed by workers, while the other 30 percent fell on employers. Gruber (1997) reports evidence of an even larger wage shift in the aftermath of the 1981 pension reform in Chile. The 1981 reform reduced employer-paid labor taxes and increased taxes paid by employees. In addition, the funding of some programs was shifted to general revenue. Using this tax change as a “natural experiment” and data on individual firms’ payments in labor taxes and wages, he seeks to determine whether lower employer-paid labor taxes are associated with higher wages within a firm. His results suggest a full shift of payroll taxes to wages and no effect on employment.<sup>16</sup>

Marrufo (2001) examines the 1997 reform in Mexico, which, as in Chile, transformed the pay-as-you-go pension system into an individual retirement accounts (IRA) system. She finds evidence of substantial employment reallocation between noncovered and covered sectors, suggesting that the labor supply to covered sectors is fairly elastic. However, she also finds evidence of a wage shift in response to a reform that ties benefits to taxes collected. Decomposing the effect of the reforms into the effect of a tax reduction and the effect of tying benefits to contributions, she finds that increasing social security taxes reduces wages by 43 percent of the tax increase, while increasing benefits decreases wages by 57 percent of the value of benefits.

An important factor determining the extent of wage pass-through is whether minimum wages bind. Maloney and Nuñez Mendez (chap. 1 in this volume) document that the minimum wage binds in Colombia. This explains the weak pass-through effects reported by Cárdenas and Bernal (chap. 4 in this volume) for Colombia. At the same time, the minimum wage is less binding, and pass-through effects may be more substantial in Mexico and Chile, and this may explain the Marrufo (2001) and Gruber (1997) results.

All in all, the available evidence suggests that at least part of the cost of

16. Measuring the impact of such an “experiment” is complicated by many factors. (See the discussion in Edwards and Cox-Edwards 2000.) First, although payroll taxes declined, worker contributions increased. If measured wage payments by firms include employee contributions, then a decline in employer-paid taxes will be associated with higher measured wages due to higher employee-paid contributions. Second, measurement error in wages biases his estimates toward finding full shifting, as he reports. The quality of his instruments is questionable, and he is forced to make strong assumptions to circumvent a severe measurement error problem. Third, at a time when social security reform made work benefits more attractive, he estimates that wages were rising. The only way that wages can rise to match the decreased employer taxes in an environment with an improved link between employee contributions and benefits is if labor supply is perfectly inelastic to covered sector firms, which seems implausible.

nonwage benefits is passed on to workers in the form of lower wages, and, therefore, the employment cost of such programs will be lower than what is predicted by the elasticity of the labor demand. Combining wage-shift and labor demand estimates indicates that a 10 percent increase in nonwage labor costs can lead to a decline in employment rates ranging between 0.6 and 4.8 percent, with most of the evidence shaded toward the high end of this spectrum.

Given the significance of these estimates for policy decisions, it is important to estimate them as accurately as possible. In this regard, the room for improvement in the literature is still large. As they stand, they might overestimate or underestimate the true employment impact depending on which of the following two effects dominates. On the one hand, the reported estimates are based on constant-output labor demand elasticities, which do not consider the employment effects of regulations through a negative effect on the scale of production of existing firms and on entry and exit decisions of firms. From this perspective, the reported range of estimates provides a lower bound on the disemployment effects of regulation. Moreover, the estimates of the wage shift in MacIsaac and Rama (1997), Mondino and Montoya (chap. 6 in this volume), and Edwards and Cox-Edwards (1999) only include the cost of social security programs, but do not include the cost of other regulations such as job security or vacation time. Once the cost of these regulations is taken into account, the computed wage shift could be lower than what we report above, and, therefore, the estimated effects of those costs on employment would be larger.

On the other hand, studies comparing wages of covered and noncovered workers performed using a cross-section of workers, such as most of the ones discussed above, may underestimate wage shifts and overestimate employment costs. It is necessary to model selection into covered sectors. This is because unobserved personal characteristics correlated with social security affiliation might explain higher wages in covered sectors.<sup>17</sup> If this correlation is substantial, it will lead to an underestimation of wage differences between covered and uncovered workers, and hence reduce estimates of the fraction of wage costs shifted to workers. This concern highlights the importance of the Marrufo (2001) study because she controls for sectoral self-selection bias and still finds substantial evidence of wage shifting. If her selection adjustments to the Mexican data are typical of what would be found in other Latin American countries, the weight of the evidence in this book and the literature on firm entry in response to incentives suggest that the studies reported in this volume underestimate the disemployment effects of regulation.

17. For instance, if workers covered by social security programs also happen to be more productive, then they will also have higher wages. Yet, higher wages are explained by unobserved productivity and not by social security affiliation.

#### I.4.2 Job Security Provisions Alter Hiring and Firing Decisions

Regulations affecting transition costs are not adequately analyzed within a simple static labor demand–labor supply framework. Dismissal costs and other regulations not only increase labor costs, but also alter firms' firing and hiring decisions. The importance of dismissal costs in Latin America is clearly shown in figure 5. Where nonwage labor costs are low relative to those of OECD countries, dismissal costs tend to be very high. These costs make Latin American labor markets less flexible than OECD markets and likely impair productivity and adaptation to new technology and trade patterns as they do in Europe (see Heckman 2003). It is thus important to assess the impact, if any, that such policies have on the functioning of the labor market.

##### *Theoretical Discussion*

To analyze the full impact of job security provisions requires a more complex framework that encompasses dynamic decisions of firms. Bertola (1990) and Bentolila and Bertola (1990) develop dynamic partial-equilibrium models to assess how a firm's firing and hiring decisions are affected by dismissal costs. In the face of a given shock, the optimal employment policy of a firm involves one of three state-contingent responses: (1) dismissing workers, (2) hiring workers, or (3) doing nothing. Appendix B presents a simple two-period model of labor adjustment that summarizes the main ideas in this literature.

In the face of a negative shock and declining marginal value of labor, a firm might want to dismiss some workers. However, it faces a dismissal cost in most regulatory regimes in LAC. This cost has the effect of discouraging firms from adjusting their labor force, resulting in fewer dismissals than the number of dismissals that would occur in a scenario in the absence of such costs. Conversely, in the face of a positive shock, firms might want to hire additional workers but would take into account that it would be costly for some workers to be fired if future demand declined. This potential cost acts as a hiring cost, effectively reducing the creation of new jobs in a relatively healthy economy. The net result is lower employment rates in expansions, higher employment rates in recessions, and lower turnover rates as firms hire and fire fewer workers than they would in the absence of adjustment costs.

Adjustment costs produce a decline in employment variability associated with firing costs. The implication of these models for average employment is ambiguous. In particular, whether average employment rates increase or decline as a result of firing costs depends on whether over the cycle the decline in hiring rates more than compensates for the reduction in dismissals. Simulations reported in Bertola (1990) and Bentolila and Bertola (1990) suggest that average employment in a given firm is likely to increase when firing costs increase. However, these results are quite sensi-

tive to different assumptions about the persistence of shocks, the elasticity of the labor demand, the magnitude of the discount rate, and the functional form of the production function. Less persistent shocks and lower discount rates produce larger negative effects of job security on employment because both factors reduce hiring relative to firing (Bentolila and Saint-Paul 1994; Bertola, 1992). Furthermore, a higher elasticity of the demand for goods implies a larger negative effect of job security on employment rates. In addition, when investment decisions are also considered, firing costs lower profits and discourage investment, increasing the likelihood that they reduce the demand for labor (Risager and Sorensen 1997).

The Bertola (1990) and Bentolila and Bertola (1990) analyses focus on employment rates in a “representative” firm without considering the impact of firing costs on the extensive margin, that is, on how firing costs affect the creation and destruction of firms. Hopenhayn and Rogerson (1993) develop a general equilibrium model based on the U.S. economy. The partial equilibrium framework of Bertola (1990) is embedded in their model as part of a general equilibrium framework in which jobs and firms are created and destroyed in every period in response to firm-specific shocks. In the context of their model, Hopenhayn and Rogerson (1993) find that increasing firing costs in the United States would lead to an increase in the average employment of existing firms as a consequence of the reduction in firings. However, they also find that such a policy would result in lower firm entry and lower job creation in newly created firms. These final two effects could potentially offset the increase in employment in existing firms, and they would thus reduce overall employment rates.

The recent literature has also emphasized the possible impact of job security regulations on the composition of employment. Kugler (chap. 3 in this volume) proposes a model in which job security regulations provide incentives for high turnover firms to operate in the informal sector. This decision would entail producing at a small, less efficient scale in order to remain inconspicuous to tax and labor authorities. In this framework, high job security costs paid by formal sector firms would likely increase informality rates. Pagés and Montenegro (1999) develop a model in which job security provisions, which depend on tenure, bias employment against young workers in favor of older ones. As severance pay increases with tenure, and tenure tends to increase with age, older workers become more costly to dismiss than younger ones. If wages do not adjust appropriately, negative shocks result in a disproportionate share of layoffs among young workers. Therefore, job security based on tenure results in lower employment rates for the young, relative to older, workers because it reduces hiring and increases layoffs for young workers. This effect has also been found in studies of European employment (Heckman 2003).

Finally, it is important to understand that not all components of dismissal costs may have the same effect on employment and unemployment

rates. Thus, in principle, there is an important conceptual distinction between advance notice and indemnities, which are state contingent and affect the cost of adjustment to different states, and seniority pay provisions, which are paid in all states and do not affect transitions. The latter are more comparable to other nonwage costs such as vacation and other mandatory benefits.

The existing evidence regarding the impact of employment protection is abundant but inconclusive. Table 5 from Addison and Teixeira (2001) summarizes the current literature. While Addison and Grosso (1996), Grubb and Wells (1993), Lazear (1990), Heckman and Pagés (2000), Nickell (1997), and Nicoletti and Scarpetta (2001) find a negative relationship between job security provisions and employment, other studies, such as Addison, Teixeira, and Grosso (2000), (Organization for Economic Cooperation and Development [OECD] 1999), Garibaldi and Mauro (1999), and Freeman (2002) do not find evidence of such a relationship. The evidence on the effects of job security on unemployment is equally ambiguous. Some studies find a positive link between job security and unemployment (Addison and Grosso 1996; Elmeskov, Martin, and Scarpetta 1998; Lazear 1990), while others find no effect (Blanchard 1998; Heckman and Pagés 2000; Nickell 1997). Our own estimates at the end of this chapter give reasons for these mixed findings. All these studies are based on the analysis of aggregates of cross-country time series data with little variation in regulatory policies. The studies presented in this volume surmount some of these difficulties by studying episodes of major labor reform using large micro-data sets. Using disaggregated data for single countries, Mondino and Montoya (chap. 6 in this volume) and Saavedra and Torero (chap. 2 in this volume) find a large negative relationship between employment protection and employment. The studies presented in this volume contribute substantially to a literature that analyzes the consequences of reforms. Recent studies for OECD countries using disaggregated data suggest a negative effect of job security regulations on employment. Autor, Donohue, and Schwab (2003) estimate the effects of recent common law wrongful discharge doctrines adopted by courts across states in the United States that limit employment at will. They find that the wrongful discharge doctrine has a negative impact on employment to population rates in state labor markets. Similarly, Kugler, Jimeno, and Hernanz (2002) find that in Spain a combination of a reduction in payroll taxes and the reduction of dismissal costs increased the employment of workers on permanent contracts. Finally, Acemoglu and Angrist (2001), and the earlier work of Deleire (2000), examine the effects of the Americans with Disabilities Act (ADA), which outlaws discrimination against the disabled in hiring, firing, and pay on the employment rate of workers with disabilities. The Acemoglu and Angrist findings and prior work by Deleire (2000) suggest that the passage of the act reduced employment for disabled workers.

Table 5 Effects of Employment Protection on Employment and Unemployment: Selected Studies

Study	Sample	EP Measure	Outcome Indicator(s)	Other Variables	Methodology	Finding
Lazear (1990)	20 countries; 1956–1984	Severance pay due blue-collar workers with 10 years of service; time-varying measure	Employment population ratio, unemployment rate, average hours worked per week	Quadratic time trend and, in some specifications, controls for population of working age and growth in per capita GDP (interacted with EP measure)	Pooled time-series/cross-section estimates; selective corrections for fixed effects, random effects, and autocorrelation	In favored specifications, EP raises unemployment and reduces employment participation and hours.
Addison, Teixeira, and Grosso (2000)	As above	As above	As above	As above, but uses full Lazear specification	Fixed and random effects, with correction for autocorrelation, plus FGLS estimates	EP is statistically insignificant.
OECD (1993)	OECD 19 countries; 1979–1991	Severance pay and notice periods combined across blue-collar and white-collar workers; moment-in-time indicator	Long-term unemployment	UI benefit duration; ALMP expenditures divided by UI benefit expenditures	Pooled time-series/cross-section estimation	EP has positive effects on jobless duration, especially in southern Europe.
Grubb and Wells (1993)	11 EU countries; 1989	Authors' own indicators of ORDW, RDSM, RFTC, and RTWA	Employment; self-employment; part-time work; temporary work; agency work	None	Simple cross-section regressions	ORDW reduces employment, increases self-employment, and reduces part-time work. RDSM (RFTC) increases (decreases) temporary work. RTWA but not RDSM reduces temporary agency work.

*(continued)*

Table 5 (continued)

Study	Sample	EP Measure	Outcome Indicator(s)	Other Variables	Methodology	Finding
Scarpetta (1996)	17 OECD countries; 1983–1993	OECD strictness ranking for regulation of dismissal averaged over regular and fixed-term contracts (OECD 1994, Table 6.7, panel B, col. 2)	Structural unemployment, plus separate regressions for youth unemployment, long-term unemployment, and nonemployment rates	ALMP calculated as expenditure on active measures per person relative to output per capita; summary index of UI benefits (OECD 1994, chapter 8); union density; union coordination, employer coordination, and their sum; centralization of collective bargaining; tax wedge; proxy for product market competition; real interest rates; output gap	Random effects, feasible generalized least squares (FGLS)	EP raises structural unemployment, with stronger effects for youth and long-term unemployment. EP increases nonemployment rate.
Elmeskov, Martin, and Scarpetta (1998)	19 OECD countries; 1983–1995	OECD (1994, table 6.7, panel B, col. 2) ranking, but modified to take account of changes since late 1980s: two-observation, time-varying indicator	Structural unemployment	ALMP (as above); UI benefits (as above); union density; dummies for the degree of coordination on the employer and union sides; dummies for degree of centralization of collective bargaining; tax wedge; output gap, minimum wage relative to average wage	Random effects, FGLS	EP raises structural unemployment but interaction effects are important. EP not statistically significant in either highly centralized/coordinated or decentralized bargaining regimes.

Nickell (1997)	20 OECD countries; 1983–1988 and 1989– 1994	OECD (1996, table 6.7, panel B, col. 5) ranking; also use of labor standards mea- sure covering in ad- dition to EP working time, minimum wages, and employee representation rights (OECD, 1994, table 4.8, col. 6)	Employment- population ratio for whole working-age population and for prime-age males; Overall labor supply (defined as actual annual hours divided by normal annual hours multiplied by employment- population ratio); Log unemployment rate and component short- and long-term rates	UI benefit replace- ment rate; UI benefit duration in years; union density; union coverage index; sum of indices of union and employer coordi- nation; instrument for ALMP expendi- ture; tax wedge; change in inflation	GLS random effects using two cross sections	EP reduces overall employment rate but not that of prime-age males. EP also reduces overall labor supply. For unemployment, EP effect is negative but statistically insignificant. EP re- duces short-term unemployment and increases long-term unemployment. Coefficient estimate for worker labor standards variable is statistically in- significant in unemployment regres- sion.
Nickell and Layard (1999)	As above	As above	As above, plus mea- sures of labor and total factor produc- tivity growth, 1976– 1992	As above, plus owner-occupat- ion rate as a negative proxy for geographic mobility	As above; OLS for analysis of produc- tivity growth	As above; EP is positive and statisti- cally significant in labor and total factor productivity equations, but effect vanishes with correction for initial productivity gap.

Table 5 (continued)

Study	Sample	EP Measure	Outcome Indicator(s)	Other Variables	Methodology	Finding
OECD (1999)	19 OECD countries; 1985–1990, 1992–1997	OECD (1999, table 2.5) measures for late 1980s and late 1990s; Single overall indicator and also separate indicators for regular employment, temporary employment and collective dismissal; In some specifications further disaggregations for regular and temporary employment	Log unemployment rate, log employment-population ratio, and changes in unemployment and employment; For unemployment: separate results for prime-age males, prime-age females, youth, and low-skilled; For employment: separate results for prime-age males, prime-age females, youth, share of self-employment, share of temporary employment, and temporary employment share in youth employment	UI benefit replacement rate; UI benefit maximum duration; ALMP expenditures as percentage of GDP; degree of centralization of collective bargaining; degree of coordination of collective bargaining; trade union density; trade union coverage; tax wedge; output gap	Two-period panel estimated by random effects, GLS (changes in levels model estimated by OLS)	Irrespective of the form of the indicator, EP coefficient estimate is statistically insignificant for overall employment. It is positive and statistically significant for prime-age male unemployment (overall indicator only). For all other demographic groups EP is statistically insignificant. Further, changes in EP do not affect changes in unemployment for other than prime-age females, where the effect is negative and statistically significant (strictness of EP with respect to regular employment). For employment, the coefficient estimates for EP are negative but statistically insignificant for overall, prime-age female, youth, and temporary employment. Otherwise they are positive and in the case of self-employment statistically significant (overall EP measure and its regular employment variant). Further, changes in EP have statistically insignificant effects for overall employment and for all demographic groups. For self-employment and the share of temporary employment, some statistically significant negative effects are observed.

Garibaldi and Mauro (1999)	21 OECD countries; 1980–1998	OECD (1994, table 6.5, panel B, col. 5) ranking: Moment- in-time measure	Average growth in total civilian em- ployment	Average change in in- flation; average total taxation as share of GDP; average pay- roll taxes as share of GDP; average UI benefit net replace- ment rate for an un- employed worker (OECD 1994, chap- ter 8); union density; index of the coordi- nation collective bargaining; time dummies	Random effects, GLS; six-year averages of data (1980–1985, 1986–1991, 1992–1997)	There is a strong negative associa- tion between EP measure and em- ployment growth in cross section (for 24 out of 27 cases), but in panel re- gressions the association is less pre- cisely estimated and is statistically significant in one of five specifica- tions only.

Table 5 (continued)

Study	Sample	EP Measure	Outcome Indicator(s)	Other Variables	Methodology	Finding
Nicoletti and Scarpetta (2001)	20 OECD countries; 1982–1998	Two indicators of the stringency of the regulatory apparatus: the first is EP per se, and is based on the time-varying OECD (1999, table 2.5) measure; the second is a measure of the degree of product model regulation and is both static (based on Nicoletti, Scarpetta, and Boylaud 1999) and time varying (based on the authors' evaluation of regulation and market conditions in seven energy and service industries, 1970–1998)	Nonagricultural employment rate	Public employment rate; tax wedge union density; dummy variables for high and intermediate bargaining based on a summary indicator combining centralization and coordination; UI benefit replacement rate composite measure (OECD 1994, chapter 8); and the output gap	Fixed effects without product market regulation indicator; random effects with static product market regulation indicators and two stage regression approach, the second state involving regression of fixed country effects on the static product market regulation indicator. Also fixed effects panel estimates with time-varying EP and product market indicators	In initial fixed effects specification, EP is associated with a statistically significant reduction in employment. When EP enters in interaction with the coordination of collective bargaining dummies, its effects are negative and statistically significant for both intermediate and high coordination. The same results are obtained for the random effects and second state regressions. In each case, the negative effect on employment is stronger in countries with an intermediate degree of coordination. The effect of the static product market regulation variable is statistically significant and negative. Finally, for the fixed effect panel regressions, EP is negative and statistically significant in the basic specification. In interactive form, however, the negative coefficient estimate for EP is only statistically significant for the intermediate coordination measure. In interaction with the coordination measure, the product market regulation variable is negative throughout, but is statistically significant for low and intermediate coordination.

Di Tella and MacCulloch (1999)	21 OECD countries; 1984–1990	World Competitiveness Report data; indicator of flexibility (see text); Time-varying measure with five data points	Employment-population ratio; participation rate; unemployment rate; long-term unemployment rate; and average hours worked per week. For the first two variables, disaggregations by gender are provided.	UI benefit composite measure (OECD 1984, chapter 8), plus level of GDP. Selective results are also provided for a specification that includes union coverage, a dummy for decentralized collective bargaining, and degree of home ownership.	Random effects, least squares dummy variable (LSDV) with country fixed effects, and time fixed effects, and generalized method of moments (GMM) estimates for each outcome indicator.	Statistically significant positive association between flexibility indicator and overall employment-population ratio across all specifications. By demographic group this effect is much stronger for females than for males. Parallel results are obtained for the participation rate. Some evidence that flexibility increases average hours worked. The association between flexibility and the unemployment rate is negative throughout but not always statistically significant. The results for long-term unemployment are less precisely estimated.

Table 5  
(continued)

Study	Sample	EP Measure	Outcome Indicator(s)	Other Variables	Methodology	Finding
Heckman and Pagés (2000)	41 countries from LAC and OECD; 1980–1997 (max)	Authors' own cardinal measure based on severance pay, notice interval, and compensation for unfair dismissal (see text); Two-period time-varying measure	Employment: total, prime-age male, prime-age female, youth, and self-employment. Unemployment: total, prime-age male, prime-age female, youth, and share unemployed for more than 6 months.	Level of GDP, GDP growth, and two demographic controls, namely, female participation rate and proportion of the population aged 15–24 years	Pooled cross-section/time series, random effects, and fixed effects; results for full sample and separate samples of OECD and Latin-American nations.	EP effect is negative and statistically significant for total employment for each estimating procedure. Similar results obtained for males and youth—but not females—the impact of EP on male employment being half the total employment effect and the youth effect is almost double the average effect. EP effects for females and self-employment vary widely across estimating procedure. The results for unemployment depend on methodology and there is no statistically significant effect of EP on longer-term unemployment. Disaggregation by broad national grouping reveals that employment effects of EP by demographic group are negative and mostly statistically significant. The exception is females in the Latin-American grouping. The effects on EP on unemployment are nearly always positive and stronger for the OECD grouping.

Freeman (2002)	23+ countries; 1970–1990	Fraser Institute index of economic freedom (see text); time-varying measure with 6 data points	Level of log GDP per capita, log employment-population ratio, log GDP per employee; and unemployment rate; also changes in levels for the first three variables	Squared freedom index term (in some specifications); country dummies; time dummies	Cross section and “panel” estimates	Countries with a high degree of economic freedom have higher GDP per capita, high employment-population rates, high GDP per employee, and low unemployment—at least in terms of levels. With the exception of unemployment these results do not survive the inclusion of country fixed effects. Estimating GDP per capita in levels and change form for a sample of less developed countries produces statistically significant positive coefficient estimates for the freedom indicator in cross-section and panel estimates.

*(continued)*

Table 5 (continued)

Study	Sample	EP Measure	Outcome Indicator(s)	Other Variables	Methodology	Finding
Blanchard and Wolfers (2000)	20 OECD countries; 1960–1999; 8 five-year averages of data	Static and time-varying measures; static measure taken from Nickell (1997); time-varying measure taken from Lazear (1990) and updated	National unemployment rates (i.e., non-standardized). Basic argument is that unemployment can be explained by shocks which interact with labor market institutions. Shocks are first modeled as common and unobservable and then as country specific.	Basic specification uses 7 (other) labor market institutions taken from Nickell (1997); alternative specification(s) uses two measures of UI benefits (authors' own calculations) that are deployed in fixed and time-varying form	Nonlinear least squares with time effects are interacted with fixed institutions/time-varying institutions; robustness checks offered; nonlinear least squares with country-specific observable shocks (total factor productivity growth, the real rate of interest, and a labor demand shift measure) that are interacted with all 8 labor market institutions; as before, estimates provided for fixed and time-varying institutions	Shock-EP interaction terms point to amplification of the effects of adverse shocks. Essentially the same is true for the remaining institutional variables with two exceptions. The exceptions are coordination of collective bargaining and active labor market policies, which ameliorate the effects of adverse shocks. In general, much weaker interaction effect and poorer fit when static EP (and UI) measures replaced by their time-varying counterparts.

Source: Addison and Teixeira (2001).

Notes: EP = employment protection; UI = unemployment insurance; ALMP = active labor market policy; ORDW = restrictions on overall employee work; RDSM = restriction on dismissal of regular workers; RFTC = restrictions on fixed-term contracts; RTWA = restrictions on temporary work agencies.

*Empirical Evidence for Latin America and the Caribbean*

The essays assembled in this volume assess the impact of job security regulation on employment and turnover rates in LAC and provide the first systematic evidence of its impact on the labor market. Several studies assess the impact of job security on turnover rates in the labor market. Changes in turnover are measured using changes in the duration of jobs (tenure), the duration of unemployment, and rates of exiting out of employment and unemployment.<sup>18</sup> Higher employment exit rates indicate more layoffs (or more quits), while higher exit rates out of unemployment and into formal jobs indicate higher job creation in the formal sector. Other studies examine the impact of job security on employment rates. The definition of employment used in the empirical studies varies, depending on the country being analyzed. In general, most studies focus on employment in large firms, although some also examine more aggregated measures of employment. In addition, a small group of studies also examine the impact of job security on the composition of employment. See table 6 for an overview of the empirical evidence for LAC presented in this volume.

*Turnover Rates*

As predicted by most theoretical models, the bulk of empirical evidence reported in this volume confirms that less-stringent job security tends to be associated with higher turnover and greater flexibility in the labor market. Kugler (chap. 3 in this volume) analyzes the impact of the 1990 labor market reforms in Colombia. She finds that a reduction in job security costs reduces average tenure and increases employment exit rates.<sup>19</sup> This decline is significantly larger in the formal sector, which is covered by the regulations, than in the uncovered or informal sector. In addition, the increase is greater in large firms than in the small ones. Her results show similar patterns within tradable and nontradable sectors, providing a clear indication that the decline in tenure cannot be attributed to contemporary trade reforms. The increasing use of temporary contracts explains only part of the increase in formal turnover rates because job stability also declined for workers employed at permanent jobs.<sup>20</sup>

Kugler also finds a decline in the average duration of unemployment

18. These studies estimate hazard rates. The hazard rate is defined as the rate at which a given spell of employment or unemployment ends in a given period conditional on having lasted a given period of time in the spell (e.g., one month, one year).

19. In this study tenure is measured by the duration of incomplete employment spells.

20. In her study, Kugler performs two types of analyses. First, she uses a difference-in-differences estimator to analyze whether changes in average duration of employment (unemployment) are significantly different in the formal and informal sectors. Second, she estimates an exponential duration model to control for changes in demographic covariates, pooling data from before and after the reform and using interaction terms to assess the differential impact on the formal and informal sectors.

Table 6 Summary of Existing Evidence on the Impact of Job Security (JS) Costs in Latin America

Study	Country	Data	Results
		<i>A. Studies that Analyze Exit Rates Into and Out of Employment</i>	
Kugler (chap. 3 in this volume)	Colombia	Household data	Decline in JS leads to reduction in employment and unemployment duration; some effect due to deregulation of temporary contracts but not all.
Saavedra and Torero (chap. 2 in this volume)	Peru	Household data	Lower JS leads to lower average tenure; higher decline in formal sector; hazard rates increase just at the end of probation period.
Barros and Corseuil (chap. 5 in this volume)	Brazil	Employment Surveys, administrative data, and household surveys	Hazard rates for short durations declined but hazard rates for longer durations increased after an increase in job security. No effects either on adjustment costs or wage elasticities.
Hopenhayn (chap. 9 in this volume)	Argentina	Household data Rotating Panel	Deregulation of temporary contracts leads to increase in hazard rates; hazard rates for short spells (1–3 months) increase by 40% and for 3–6 months spells by 10%.
		<i>B. Studies that Analyze Average Employment and Unemployment</i>	
Kugler (chap. 3 in this volume)	Colombia	Household data on employment	Decline in JS in 1990 brings a decline in unemployment rates. This is based on computing the net effect of changes in hazard rates, in and out of unemployment, induced by the reduction in JS.
Saavedra and Torero (chap. 2 in this volume)	Peru	Firm and sector level data; 1986–1997	They include a direct measure of JS regulations in labor demand function. They estimate a negative and statistically significant coefficient, which is larger (in absolute value) in the more regulated period.
Mondino and Montoya (chap. 6 in this volume)	Argentina	Panel of manufacturing firms; does not account for firm creation	As Saavedra and Torero (this volume), they include a direct measure of JS in labor demand. They also find a negative effect of JS on LD.

Table 6 (continued)

Study	Country	Data	Results
Barros and Corseuil (chap. 5 in this volume)	Brazil	Monthly establishment-level data; 1985–1998; manufacturing; firms employing 5 or more workers	Two step procedure: First, find parameters for labor demand (LD) function for every month; then see whether those parameters change with labor reforms and other development. They find no effect of JS on LD parameters.
Downes, Mamingi, and Antoine (chap. 10 in this volume)	Barbados Trinidad; Jamaica	Aggregated employment. Annual; covers large firms (> 10 emp)	The effects of JS on employment are statistically insignificant and the signs are positive in some cases.
Pagés and Montenegro (1999)	Chile	Household data on employment; annual; 1960–1998	Not a significant effect of JS on aggregated employment but important effect on its composition.
Marquéz (1998)	Cross-country	Cross-section data for LAC and OECD countries	Rank indicator of JS; not significantly associated with lower employment once GDP per capita is accounted for.
Marquéz (1998)	Cross-country	<i>C. Studies that Analyze the Composition of Employment</i> Cross-section data for LAC and OECD countries	Self-employment rates are positively associated with JS even after accounting for differences in GDP per capita.
Montenegro and Pagés (chap. 7 in this volume)	Chile	Household survey data; 1960–1998	Job security is associated with lower employment rates for young workers, female and unskilled workers, and higher employment for older and skilled workers.

after the reforms. In addition, exit rates out of unemployment increase more for workers who leave unemployment by going into the formal sector than they do for those who exit into informal jobs. As with average tenure, her results show quite similar patterns across sectors and a higher exit rate toward larger firms. Finally, only two-thirds of the increase in the rate of entry into unemployment can be attributed to higher use of temporary contracts. The rest is explained by increased exit rates into permanent jobs in the formal sector.

Saavedra and Torero (chap. 2 in this volume) conduct a similar study, evaluating the impact of the 1991 reform in Peru. Like the reform in Colombia, the 1991 Peruvian reform considerably reduced the cost of dismissing workers. Their analysis shows a consistent decline in average tenure from 1991 onward, suggesting higher exit rates from employment. As in the Kugler study, the decline is significantly more pronounced in the formal sector than it is in the informal sector. In addition, the tenure patterns were quite similar across economic sectors, suggesting that these findings cannot be explained by the trade reforms that took place in the early 1990s.

In contrast to these findings, Barros and Corseuil (chap. 5 in this volume) find little evidence that the substantial 1988 Brazilian Constitutional reform altered employment exit rates. In that year, the cost of dismissing workers was raised, and, therefore, a reduction in exit rates would be expected as a result. (Many other reforms were also put in place as well.) Their results indicate that aggregate employment exit rates decline in the formal sector relative to the informal sector for short employment spells (two years or less), but increase for longer spells. Their measured increase in exit rates for long spells could be driven by the special characteristics of the Brazilian system. In this system, employers contribute 8 percent of a worker's wage to the worker's individual account. In case of involuntary dismissal, the worker can claim the principal, the compounded interest rate, and a penalty paid by the firm, which in the 1988 reform was raised from 10 percent to 40 percent of principal plus interest. In the case of a voluntary quit, the worker receives nothing. This asymmetry in the treatment of termination induces workers to force dismissal or to collude with firms to obtain the funds accumulated in the account. It can be argued that the 1988 reform greatly increased the incentives to force dismissals, particularly for workers with longer tenures. This may explain the increase in exit rates for workers with longer employment spells.

These three studies use the informal sector as a control group unaffected by the reforms. Their credibility hinges on the validity of this assumption. Kugler shows that estimates based on formal-informal sector comparisons are likely to be biased. However, such comparisons are still valid under certain conditions—at least as tests of the null hypothesis of no effect of the

reform.<sup>21</sup> When viewed as a whole, these studies provide evidence that dismissal costs and other employment protection mechanisms reduce worker reallocation in the labor market. Unfortunately, these studies do not identify whether reduced worker reallocation is due to reduced layoffs, lower quits, or a mix of both.

Some studies in this book assess the impact of regulations on the speed of adjustment using the length of the lag (the speed of adjustment) as an alternative measure of the constraints faced by firms. The intuition supporting this is based on the original work of Holt et al. (1960).

Let  $n_t^*$  be the optimal level of employment at date  $t$  determined by some implicit (usually static) theory. Let the cost of being out of equilibrium,  $c_t^0$ , be quadratic in deviations of current employment from optimal employment:

$$(2) \quad c_t^0 = \gamma_0(n_t^* - n_t)^2 \quad \gamma_0 > 0$$

The greater the discrepancy between employment at  $t$  and optimal employment, the greater the cost. There is also a cost of adjustment,  $c_t^a$ , which is also assumed to be quadratic in the adjustment from  $n_{t-1}$  to  $n_t$ :

$$(3) \quad c_t^a = \gamma_a(n_t - n_{t-1})^2$$

Minimizing the sum of these costs produces an optimal labor demand  $n_t$ :

$$n_t = (1 - \lambda)n_t^* + \lambda n_{t-1},$$

where

$$\lambda = \frac{\gamma_a}{\gamma_a + \gamma_0}.$$

The greater the cost of adjustment, the bigger the value of  $\lambda$ . Abraham and Houseman (1993) and many others use this method to assess the effect of different regulatory regimes across countries on adjustment costs, while others interact  $\lambda$  with measures of regulations to assess whether the speed of adjustment increases or declines when the regulatory environment is changed. Cárdenas and Bernal (chap. 4 in this volume), Barros and Corseuil (chap. 5 in this volume) and Saavedra and Torero (chap. 2 in this volume) use this methodology to examine whether the speed of adjustment increased or declined after labor reforms. In the study of Saavedra and Torero, their estimated interaction term suggests that more stringent regu-

21. Kugler shows that lower severance pay may induce high-turnover informal firms to move to the formal sector. Assuming either no overlap in the distribution of turnover between covered and uncovered firms or that entry to the covered sector comes from the high-end—or at least from the end that is higher than the formal sector—this shift results in higher turnover in both the formal *and* the informal sector. Higher turnover in the informal sector biases the difference-in-differences estimator downward. Therefore, a positive estimate still provides substantial evidence of increased turnover in the formal sector.

lations reduce the speed of adjustment, particularly in the prereform period, when regulation was very stringent. In the other two studies, this methodology is unable to identify any changes in adjustment due to reforms. This is particularly relevant in the study of Cárdenas and Bernal on Colombia because other methodologies based on duration data (Kugler, chap. 3 in this volume) show clear effects of regulation on adjustment. Addison and Teixeira (2001) indicate that “none of the implementations of this (adjustment cost) model in core OECD countries were able to detect a discernible impact of job security regulations on the speed of employment adjustment.” In the concluding section of this paper, we discuss why the lag coefficient is not a reliable measure of the regulatory costs, especially when applied to cross-country data.

### *Average Employment*

The available evidence for LAC countries shows a consistent, although not always statistically significant, negative impact of job security provisions on average employment rates. Saavedra and Torero (chap. 2 in this volume) and Mondino and Montoya (chap. 6 in this volume) use firm-level panel data to estimate the impact of job security on employment in Peru and Argentina, respectively. Both studies estimate labor demand equations in which an explicit measure of job security appears on the right-hand side of the equation, and both find evidence that higher job security levels are associated with lower employment rates.<sup>22</sup> In the case of Peru, Saavedra and Torero find that the size of the impact of regulations is correlated with the magnitude of the regulations themselves. Thus, the impact is very high at the beginning of their sample (1987–1990), coinciding with a period of very high dismissal costs (see their table 4). Afterward, and coinciding with a period of deregulation, the magnitude of the estimated coefficient declines after a new increase in dismissal costs, only to increase again from 1995 onward. Their estimates for the long-run elasticities of severance pay are very large (in absolute value). Between 1987 and 1990, a 10 percent increase in dismissal costs is estimated to reduce long-run employment rates by 11 percent, keeping wages constant. In subsequent periods, the size of the effect becomes smaller but is still quite large in magnitude (between 3 and 6 percent). In Argentina, the estimated long-run elasticity of a 10 percent increase in dismissal costs is also between 3 and 6 percent.<sup>23</sup>

22. The data for the Peruvian study covers firms with more than ten employees in all sectors of the economy. The Argentinean study only covers manufacturing firms. Given the nature of these surveys, these studies analyze formal employment rather than employment as a whole. The data used in these two studies does not capture job creation by new firms, because both panels are based on a given balanced panel census of firms, which does not adjust for attrition.

23. The methodology used by these studies might lead to upward biased estimates of the elasticity of employment to job security. Thus, for example, Mondino and Montoya construct explicit measures of job security based on

Kugler (chap. 3 in this volume) computes the net impact of the Colombian 1991 labor reform on unemployment rates. Using unemployment and employment exit rate estimates before and after the reform, she finds that the reforms cause a decline in unemployment between 1.3 and 1.7 percentage points. Thus, as in Mondino and Montoya (chap. 6 in this volume) and Saavedra and Torero (chap. 2 in this volume), Kugler's estimates of the impact of deregulation indicate that the positive impact of reduced labor costs on hiring outweighs the negative impact of reduced severance costs on firing, resulting in a decline in unemployment rates.

Heckman and Pagés's (2000) analysis of cross-section time series aggregates also finds evidence of a negative impact of employment protection on employment. However, the evidence presented at the end of this chapter suggests that their results for Latin America are not robust, although their results for OECD Europe are robust. The fragility of their estimates for Latin America, based on aggregate data, suggests the value of using more disaggregated data in reaching sharp conclusions.

Other studies find negative, but statistically less precisely estimated, effects of job security on average employment rates. Pagés and Montenegro (1999) find that job security has a negative but statistically insignificant effect on overall wage-employment rates in Chile. Similarly, Marquéz (1998), using a cross-section sample of Latin American and OECD countries, finds a negative but insignificant coefficient of job security on aggregate employment rates. Table 6 summarizes the various estimates of job security on employment.

Downes, Mamingi, and Antoine (chap. 10 in this volume) also use aggregate time series data to examine changes in the labor demand associated with changes in the regulatory framework in three Caribbean countries. Their inconclusive results are typical of an entire literature. They use an indicator variable that measures periods with more or less stringent regulations. Their estimates do not capture changes in labor demand before and after the reform. However, as in the case in most of the OECD-based literature, their sample variation in regulations and institutions may be too limited and the level of aggregation too great to capture any effects of regulation on employment.

$$JS_j = \delta_j T_j P_j SP_j,$$

where  $\delta_j$  is the average layoff rate in sector  $j$ ,  $T_j$  is average tenure in sector  $j$  for a time period  $t$ ,  $P_j$  is the share of firms in sector  $j$  for time period  $t$  that are covered by regulations, and  $SP_j$  is the mandatory severance pay in sector  $j$ , given average tenure  $T_j$ . This measure provides variability across sectors and periods, and, therefore, it yields a more precise estimation of the impact of job security than before-after types of comparisons. Yet, such a measure may also be correlated with the error term in a labor demand equation because both layoffs and the tenure structure of a firm might be correlated with its employment level. However, robustness analyses reported in Mondino and Montoya suggest that not considering some of this variability still produces positive and statistically significant estimates for the coefficient of the job security measure.

*The Composition of Employment*

Economists have paid relatively more attention to studying the effects of job security on the level of employment and unemployment than to studying the effects of such policies on the distribution of jobs. However, a few studies shed some light on the impact of job security on the composition of employment in LAC. Marquéz (1998) constructs a ranking of the relative severity of labor market regulations (including workweek, contract, and other regulations besides job security provisions) for LAC and OECD countries and uses it to estimate the effects of job security on the formal and informal distribution of employment. He finds that across countries, more stringent regulations coincide with a larger percentage of self-employed workers. In a study of Chile, Montenegro and Pagés (chap. 7 in this volume) use repeated cross-section microdata spanning forty years of data and substantial variation in labor market policies. They control for year effects that are common across workers, as well as for the differential effects of the business cycle and other labor market policies on each demographic group. They find that more stringent job security measures reduce the employment rates of youth and the unskilled, while increasing the employment rates of older and skilled workers. Their results also suggest that job security regulations increase the self-employment of women and unskilled workers, relative to other demographic groups. This evidence is consistent with evidence in Bertola (2001) and Heckman (2003) that job security provisions protect the relatively privileged workers at the expense of the less advantaged ones. In a review of the recent OECD literature, relying on cross-country time series analysis, Addison and Teixeira (2001) reach similar conclusions, stating that while prime-age male employment rates have not been affected by job security provisions, the employment rates of other groups, most notably younger workers, have been affected.

#### I.4.3 Temporary Contracts

Hopenhayn (chap. 9 in this volume) discusses the impact of temporary contracts on the Argentine labor market. Such contracts were introduced following the Spanish model. He finds that these contracts induce an increase in hiring and a substitution away from long-term employment toward short-term employment. So, in the short run, these contracts remove one barrier from the labor market and make it more fluid. At the same time, they tend to promote turnover. Hopenhayn finds that the average hazard rate for the first three months out of employment increased by 30 percent and for tenure above three months by 10 percent. While temporary contracts promote fluidity, they reduce firm attachment and the incentive of firms to invest in workers. Alonso-Borrego and Aguirregabiria (1999) document that in Spanish labor markets, the effect of temporary contracts is to reduce investment in workers and hence to produce lower quality (less-skilled) workers in the long run.

#### I.4.4 Minimum Wages

Maloney and Nuñez Mendez (chap. 1 in this volume) present novel estimates of the impact of minimum wages on wage distributions and employment. Their evidence demonstrates convincingly that minimum wages are binding in many Latin American countries and have substantial effects on employment and wage distributions. An important finding in their analysis is that both covered and uncovered sectors (“formal” and “informal” sectors) respond in similar fashion to wage minimums. The informal sector does not show the downward wage flexibility that traditional models of labor market dualism predict. Another important finding is that minimum wages percolate much more widely across wage distributions in Latin America than they do in the United States. There are substantial effects of minimum wages on wages far up in the distribution of wages. Their study puts to rest the claim that minimum wages are innocuous, even in countries with large “informal” sectors.

Montenegro and Pagés (chap. 7 in this volume) study the effects of minimum wages on the distribution of employment in Chile. They find that, like job security provisions, minimum wages reduce the employment probabilities of the young and the unskilled, relative to older and more skilled workers. Not surprisingly, as suggested in other studies for developed countries, their results indicate that minimum wages are particularly binding for young unskilled workers. However, their results also indicate an adverse effect of the minimum wage on prime-age unskilled workers. Minimum wages adversely affect disadvantaged workers of all ages.

We next turn to a pooled time series cross-country study of the impact of regulation on employment. The fragility and sensitivity of the estimates for the Latin American region that we find highlight the benefits of the micro-data analysis reported in this volume.

### **I.5 Evidence from a Cross-Section Time Series Sample of LAC and OECD Countries**

In this section, we summarize and expand on some of the main results of our recent work, updating our earlier paper (Heckman and Pagés 2000). We use time series of cross sections of countries, and we exploit the substantial variability in labor laws in Latin America to estimate their effects on employment and unemployment. These studies serve to place the chapters in this volume within the broader context of a literature that almost exclusively focuses on time series of cross-section averages of countries. Unfortunately, few empirical regularities emerge when an honest sensitivity analysis is conducted. Nonetheless, a few robust regularities do appear. Payroll taxes reduce employment and (less robustly) in OECD countries, job security regulation reduces employment.

### I.5.1 The Data

Labor market studies focusing on developing countries are hampered by serious data problems. Thus, labor market variables contained in most cross-country databases suffer from a lack of comparability and reliability. To overcome these problems, we construct a new data set that includes OECD and LAC countries. For OECD countries, we collect employment and unemployment data from the OECD statistics. For the Latin American sample, we directly construct the same indicators out of a large set of Latin American household surveys. See appendix A for a more detailed description of the employment and unemployment variables as well as the countries and years used to obtain the LAC data. Population variables are obtained from the United Nations (UN) population database while GDP measures are from the World Bank development indicators. To characterize labor market regulations, we use the set of measures summarized in table 4, defined for each year and country.

Our joint sample collects more than 400 data points from thirty-eight countries; twenty-three in the OECD and fifteen in the LAC. (Mexico is included in the Latin America sample although it belongs to the OECD.) We analyze country means and do not disaggregate further. The sample is an unbalanced panel covering the period 1983–1999. Table 7 reports summary statistics of our data for both our whole sample and for the sub-regional ones.<sup>24</sup> There are large differences between the OECD and the LAC samples. The GDP per capita measures tend to be substantially lower in the LAC than in the OECD region. Conversely, GDP growth is lower in the latter. Indemnities for dismissal and seniority pay are higher in Latin America than in OECD countries, while advance notice provisions and social security contributions are lower. There are important differences in labor market aggregates as well. On average, employment rates are higher in the LAC region than in OECD countries. The reverse is true for unemployment rates. The LAC region also displays a lower percentage of the working-age population in the twenty-five to fifty-four-year-old and the fifty-five to sixty-five-year-old brackets than OECD countries and a higher share of the population in the fifteen- to twenty-four-year-old age group. By constructing our own data set from individual household-level surveys, we are guaranteed that all of the labor market variables are comparable and reliable. One drawback of our data is that for the LAC sample, we only have a few time series observations per country (usually six or seven), and not necessarily from consecutive years.

Our objective is to relate our measures of regulations to employment

24. Table 7 reports the data used in the baseline specification (see also table 8, column [1]). In the specifications where regulations are entered one to one, the number of observations used is larger because we have more data on some regulations than on others. Restricting the sample size to be equal to the one used in the baseline specification does not alter any of the results.

**Table 7** Summary Statistics of Sample used in Baseline Regression

Variable	Mean	Standard Deviation	Min.	Max.

<sup>a</sup>Regulatory variables measured in multiples of monthly wages.

and unemployment outcomes. Although we perform multivariate analyses, it is interesting to examine the bivariate relationship between regulations and employment. This is particularly easy for regulations such as job security provisions that, within our sample, change at most once or twice per country. In figures 8 and 9, we graph employment before and after reforms for countries that experienced job security reforms. The graphs for LAC should be interpreted with caution because they have been interpolated from incomplete time series data.

There is little evidence that reforms that reduced job security increased employment rates in Colombia. There is also not much evidence that reforms that increased job security had a deleterious effect on employment in Brazil, Chile, or Nicaragua. However, there is some evidence indicating that reforms that liberalized labor markets in Peru increased employment rates, while reforms that increased labor market rigidities reduced employment. For Germany, our data suggest that employment declined at a slower rate after a reform that increased job security, while in Spain and the United Kingdom the opposite seems to be true after liberalization. These figures suggest that periods of less stringent job security regulations coincide with higher employment rates in some countries, while the reverse is also true in other countries. The data presented in these figures, however, fail to control for contemporaneous changes in economic activity or other factors that could be correlated with employment and labor reforms. In the next section, we perform an empirical analysis in an attempt to control for contemporaneous effects that may be correlated with reforms, employment, and unemployment outcomes.

### 1.5.2 Methodology and Results

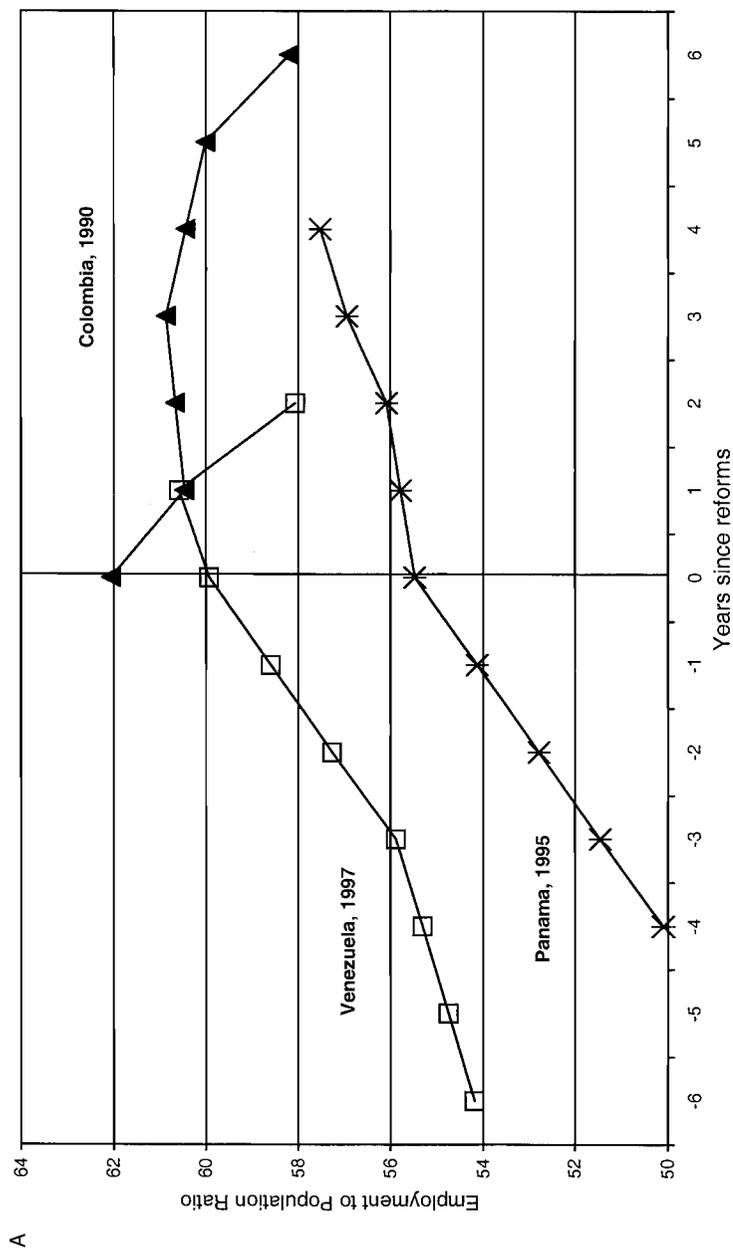

To relate labor market regulations to employment and unemployment outcomes, we estimate the following model:

$$Y_{it} = \alpha_i + \beta_1 \mathbf{X}_{it} + \beta_2 g_{it} + \beta_3 \text{GDPPC}_{it} + \beta_4 \mathbf{Z}_{it} + \varepsilon_{it},$$

where  $Y_{it}$  is a labor market variable (employment or unemployment) of country  $i$  at period  $t$ ,  $\alpha_i$  denotes a country fixed effect,  $\mathbf{X}_{it}$  denotes a vector of employment regulation variables,  $g_{it}$ , and  $\text{GDPPC}_{it}$  denote GDP growth and (log of) GDP per capita, respectively,  $\mathbf{Z}_{it}$  is a vector of demographic controls, and  $\varepsilon_{it}$  is a mean zero error.

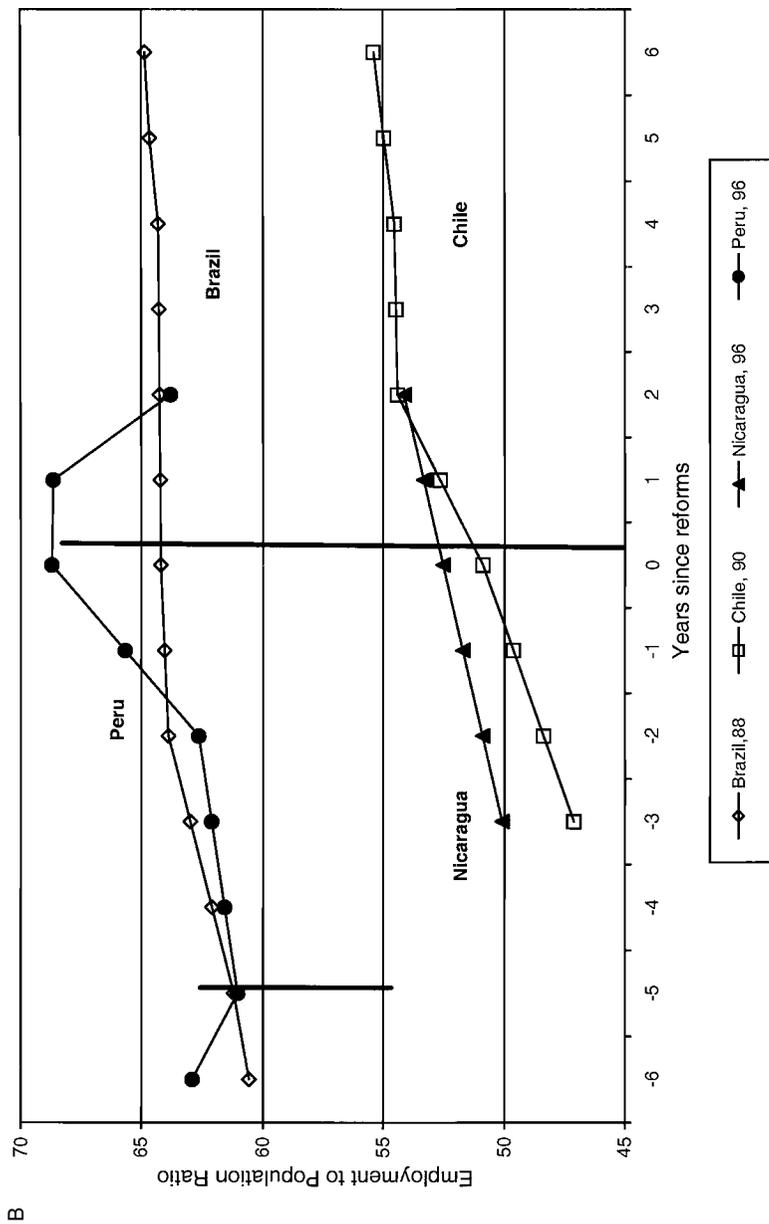

Given the nature of the data with incomplete gaps, we decided not to average observations from a given period to control for business cycle effects, as is often done in OECD studies. Instead, we control for the state of the business cycle in a given year using GDP growth.<sup>25</sup> Although a large part

25. The GDP growth is obtained from the World Bank development indicators. It turns out that deleting or including this variable has no important effect on our empirical conclusions. Deleting or including GDP per capita (PPP adjusted) does not alter our results, either.

of our variation is cross sectional, we use fixed-effects estimates to control for unobserved variables that may be correlated with measures of regulation across countries. In addition, we control for demographic changes that may be correlated with employment and unemployment rates as well as regulatory variables that change over time. Finally, we use GDP per capita (adjusted by PPP) to control for differences in levels of country economic activity across years.<sup>26</sup> We estimate a reduced form model to investigate whether periods of high nonwage labor costs stemming from advance notice, indemnities for dismissal, severance pay, or social security contributions are associated with lower employment or higher unemployment rates. We thus estimate an average net effect of labor laws as they operate through intermediate variables, which we do not include in the regression. We do not estimate a theoretically more appropriate state-contingent labor demand specification because we lack the information on the firm-specific state of the product market confronting individual firms. Therefore, we only attempt to identify the effect of labor laws through their effect on expected (across labor market states) labor cost. This is a severe limitation. However, what we offer is an improvement over the existing literature on cross-country time series that does not quantify labor costs. Appendix B discusses conceptually more appropriate specifications of labor demand functions.

26. We control for GDP growth *and* GDP per capita (PPP adjusted) because we have few data points per country and they are not necessarily contiguous, so we cannot use the simple averaging method employed in OECD studies to control for business-cycle effects.

<sup>a</sup>*P*-value of test that all regulations are jointly equal to zero.

\*\*\*Significant at the 1 percent level.

\*\*Significant at the 5 percent level.

Table 8 displays our estimates for employment in the overall and regional samples. In these and subsequent results, we compute standard errors that are robust to heteroscedasticity. Throughout this analysis, we extend social security data to yearly frequencies because this information is only available biannually. We do so either by interpolating or by inputting each missing data value with the value from the former year. The results of our empirical analysis are robust across methods. Also, the results do not vary when we consider only the original biennial data. However, in this case, the number of available observations drops substantially.

The coefficients on GDP growth have the expected positive signs and are statistically significant for the overall sample. The coefficients on the demographic variables are positive, suggesting that countries with larger percentages of their working age population above age twenty-five tend to have higher employment rates. However, none of the coefficients on the de-

mographic variables are statistically significant at conventional levels. A higher GDP per capita tends to coincide with higher employment to population rates. However, this estimated effect is not precisely determined.

Our main interest is on measuring the effect of the labor market regulations. We find that once we expand our sample to include a larger number of OECD and LAC countries, the strong negative effect on employment of indemnities for dismissal reported for the pooled sample in Heckman and Pagés (2000) disappears. This is somewhat surprising because not only do we expand the set of countries and periods for which we can construct the measure, but we also revise some of the variables used in our previous analysis to more accurately model the laws. We still estimate a negative, statistically significant coefficient for indemnities in the OECD specification, and this is an important contribution to the European debate on the impact of regulations. This evidence suggests a significant lack of robustness of the estimated effect of regulations that we explore in detail.

With regard to the rest of the regulations, we find a positive, although not statistically significant, coefficient on advance notice cost both in the joint and in the subregional samples. Because seniority pay regulations only exist in Latin America, we cannot identify the impact of these regulations in the OECD sample. However, we find positive coefficients for this variable both in the LAC and in the pooled sample. Moreover, the coefficient in the joint sample is statistically significant at the 5 percent level. The estimated coefficient suggests that an increase in payments equivalent to one month's pay (in expected present value) *increases* employment rates by 1.12 percentage points. One might argue that the strong association between contributions and benefits associated with these types of schemes contributes to an expansion of labor supply increasing overall employment rates. However, the coefficients on advance notice and on indemnities are also positive. In contrast to these results, our estimates suggest a negative effect of social security contributions on employment both in the joint and the subregional samples. (Recall that this is the total contribution of employers and workers.) This effect is statistically significant. According to our estimates, a reduction in the social security contributions from the OECD to the LAC average (see table 4) would increase employment by 3.25 percentage points for the coefficients from the joint sample or by 4.26 percentage points if the OECD coefficient is used (table 8, columns [1] and [6], respectively).

Because there is substantial correlation among our measures of labor market regulation, we also estimate specifications that include these measures one at a time.<sup>27</sup> The number of observations used in each regression

27. The correlation coefficient between advance notice, indemnities for dismissal, and seniority pay is between 0.15 and 0.21 (in absolute value) and statistically significant. Social security contributions are positively and significantly correlated with advance notice, but the correlation with the other measures is close to zero and not statistically significant.

varies because there are countries for which we do not have information for all the regulation measures. The results are unchanged if we restrict all regressions to have the same observations than the ones used in column (1). Adding the regulation measures separately tends to produce smaller coefficients for each of them, suggesting that there are important complementarities that are not captured by the one-at-a-time specifications. We strongly reject the hypothesis that the four measures are not jointly significant (last row, table 8) and therefore include them together in the remaining analysis.

Table 9 presents the estimates for unemployment. As for employment, indemnities for dismissal have a strong positive effect on unemployment in the OECD sample but no effect in the Latin America or the joint sample. The coefficient on advance notice is negative in the overall and OECD samples, but not in the LAC sample. However, the coefficient is not statistically significant in any sample. The coefficient on seniority pay is also

\**P*-value of test that all regulations are jointly equal to zero.

\*\*\*Significant at the 1 percent level.

\*\*Significant at the 5 percent level.

positive, suggesting that these schemes increase labor supply. However, the coefficient is not statistically significant. Finally, and consistent with our results on employment, we find that higher social security contributions are associated with higher levels of unemployment in the three samples considered. Our point estimates suggest that reducing social security contributions from the OECD to the LAC average reduces unemployment by 2.54 percentage points if we use the estimate for the joint sample or 3.11 percentage points if we use the OECD one. As with the case of employment, adding the regulatory measures one at a time produces smaller coefficients for each of the measures. As before, we reject the hypothesis that the coefficients of the four variables are jointly equal to zero, and, therefore, we will include them in the rest of the unemployment analysis.

Our results in tables 8 and 9 suggest that not all regulations have the same effect on employment and unemployment rates. Because all regulations are measured in multiples of monthly wages, we can compare the coefficients of the four regulations studied and assess whether they have similar effects. In table 10 we report the results of testing the hypothesis of equality of coefficients. We reject the null hypothesis of identical coefficients for the four measures in the employment, but not in the unemployment, specifications. Interestingly, we are also able to reject the hypothesis that social security payments exert the same effect on employment as seniority pay, despite the fact that both variables imply mandatory contributions defined as a fraction of wages. Perhaps because contributions to finance seniority pay are capitalized in individual accounts, the link between contributions and payments is strengthened, and this reduces or eliminates the “tax” effect. Instead, our results suggest that social security contributions tend to be perceived as taxes on labor and, therefore, reduce the demand of labor above and beyond a possible reduction in the supply of labor. Moreover, we reject the hypothesis that indemnities for dismissal and seniority pay have the same coefficient or that all components of job security (advance notice, indemnities for dismissal, and seniority pay) have the same coefficient. When we impose this (incorrect) constraint on the data, we obtain a positive but not statistically significant coefficient on job security regulations, while the coefficient on social security regulations remains negative and statistically significant.

Finally, although we reject the hypothesis that all four regulations have the same effect on employment, imposing this constraint yields a negative, statistically significant coefficient on employment and a positive, statistically significant coefficient on unemployment. Moreover, the size of the coefficients is very similar to the ones reported in tables 8 and 9 for social security. This is not surprising, because social security regulations constitute the lion’s share of the total cost of regulations.

In summary, our results suggest that not all regulations have the same effect on employment rates. Thus, while social security contributions are

negatively associated with employment (and positively associated with unemployment), the effect of job security measures on employment is ambiguous. While in the joint and LAC samples, advance notice and indemnities for dismissal have positive, although not statistically significant coefficients, the coefficient on indemnities in the OECD sample is negative and statistically significant at conventional levels. Seniority pay is positively associated with employment, and the coefficients on this variable are statistically significant in most specifications. We also reject the hypothe-

sis that the coefficients on seniority pay and the coefficients on the rest of the components of job security are the same. These differences in results across regions, specifications, and samples, relative to our previous work, suggest a lack of robustness that we further explore. Before turning to a robustness analysis, we first consider the evidence on the shifting of the payroll tax.

### *Wage Shifts*

What is the estimated wage pass-through implied by our coefficients on social security contributions? The social security effect is a robust finding of our aggregate country analysis and so is worth exploring further. Define  $\alpha$  as the elasticity of employment with respect to the cost of labor. Assume that social security taxes are expressed as a percentage of wages. Writing labor demand as a function of wages inclusive of taxes in log linear form, we obtain

$$\ln \text{EMP}(\text{SS}) = \alpha \ln[W(\text{SS})(\text{SS})] + C,$$

where  $\text{SS}$  is the fraction of wages marked up by social security and  $W(\text{SS})$  is the wage which depends on  $\text{SS}$  through equilibrium shifting effects, and  $C$  is a constant standing in for all other factors. Taking derivatives with respect to the  $\text{SS}$  markup, we obtain

$$\frac{\partial \ln \text{EMP}(\text{SS})}{\partial \ln \text{SS}} = \alpha \left( \frac{\partial \ln W(\text{SS})}{\partial \ln (\text{SS})} + 1 \right)$$

Solving for  $\frac{\partial \ln W(\text{SS})}{\partial \ln \text{SS}}$ , we obtain

$$\frac{\partial \ln W(\text{SS})}{\partial \ln \text{SS}} = \frac{1}{\alpha} \left( \frac{\partial \ln \text{EMP}(\text{SS})}{\partial \ln \text{SS}} - \alpha \right).$$

To estimate the wage shift, we estimate  $(\partial \ln \text{EMP}(\text{SS})) / (\partial \ln \text{SS})$  from a specification with the same control variables as the specification reported in table 8, column (1), but where the dependent variable is in logs, advance notice, indemnities for dismissal, and seniority pay are defined in logs, and social security contributions are defined as fractions of gross wages, and we use  $\ln(\text{SS})$  as a regressor. Finally, the elasticity of labor demand to labor costs,  $\alpha$ , is assumed to be within the ranges of estimates reported in table 4 and consistent with the estimates reported in these studies. With all of these elements, we obtain the estimates presented in table 11.<sup>28</sup>

We find that the elasticity of employment with respect to social security contributions is  $-0.7$  for the whole sample, around  $-1$  for the OECD sample and  $-0.447$  for Latin America. This implies that increasing social

28. Hamermesh (1993) reports a range of elasticities between  $-0.15$  and  $-0.7$ . We constrain wage effects of  $\text{SS}$  in table 11 to be nonpositive.

**Table 11** Estimates of Wage Pass-Through for Different Labor Demand Elasticities

	Labor Demand Elasticity	Whole Sample	OECD Sample	Latin American Sample
$\frac{\partial \ln \text{Emp}}{\partial \ln \text{SS}}$		-.702 (0.293)**	-1.048 (0.381)**	-.447 (0.270)
$\frac{\partial \ln W}{\partial \ln \text{SS}}$	-0.15	0	0	0
$\frac{\partial \ln W}{\partial \ln \text{SS}}$	-0.7	0	0	-.36
$\frac{\partial \ln W}{\partial \ln \text{SS}}$	-1.2	-.415	-.12	-.62

*Notes:*  $\partial \ln \text{Emp}/\partial \ln \text{SS}$  is obtained from a regression in which the dependent variable is computed in logarithms and all regulatory variables are also computed in logs. The other control variables used in table 8 are used here. Social security contributions are defined as logarithms of the fraction of the contribution rate, that is we use  $\ln(\text{SS})$ . Standard errors are in parentheses. The other three rows are obtained from the formula in the text, using alternative values of  $\alpha$ , as shown in the first column of the table. When estimated effects on wages are positive, they are constrained to be zero.

\*\*Significant at the 5 percent level.

security contributions by 10 percentage points will lower employment by 7 percent in the overall sample, 10 percent in the OECD and 4.5 percent in Latin America. These are large numbers. They also imply that for a large range of labor demand elasticities, the estimated pass-through is zero, particularly for the OECD sample. Thus, for a labor demand elasticity of  $-0.7$ , the pass-through is zero in OECD and 36 percent in Latin America. Although this larger pass-through in Latin America is at odds with the presumption of a very elastic labor supply to the formal sector, it is consistent with a much higher wage flexibility in Latin America than in industrial countries, due to greater inflation in the region (see IADB 2004). All in all, this evidence suggests that part of the cost of regulations is borne by workers but that social security contributions tend to be perceived as taxes on labor. Increasing social security taxes leads to substantial costs in terms of reductions in employment and increases in unemployment.

### 1.5.3 The Effect of Recent Social Security Reforms

Our negative coefficients on social security contributions suggest that the benefits associated with these contributions are valued at less than 100 percent of their cost. An interesting question is whether the recent wave of pension reforms in Latin America have contributed to strengthen the link between contributions and benefits as well as to increase the size of the wage pass-through. This is especially relevant because most reforms transformed pay-as-you-go systems into full or partial capitalization systems.

**Table 12** The Effect of Pension Reforms on Employment and Unemployment

Notes: See table 8. See table A.1 for a definition of Reform variable.

\*\*\*Significant at the 1 percent level.

\*\*Significant at the 5 percent level.

To examine this possibility we create a dummy variable, Reform, which, for each country, takes the value of zero in the period prereform and 1 from the period of reform onward (see appendix A for a full description of the periods of reform). We add this variable and an interaction of reform with the cost of social security payments to our baseline specifications (tables 8 and 9 column [1]). Our results suggest contemporaneous positive effects of pension reforms on employment. (See table 12.) However, it is unclear whether this positive effect is associated with the reforms themselves or with other factors. Thus, we find a positive and statistically significant coefficient on the Reform variable, suggesting an increase in employment rates in the postreform period. However, the interaction term with social security re-

form is negative and statistically significant, indicating that social security taxes have larger disemployment effects after the reforms. This higher disincentive could be due to the mixed effects resulting from the transition to the new system. As workers move from the pay-as-you-go to the capitalization system, contributions to social security finance individual accounts and, in many instances, the pensions of those left in the old system. The contribution to fund the old system is likely to be viewed as a pure tax on employment.

#### I.5.4 Robustness

The results reported in this section are based on larger samples and depart substantially from those reported in Heckman and Pagés (2000).<sup>29</sup> Unfortunately, a lack of robustness to changes in specification or sample size is all too common in the cross-section time-series literature that uses aggregate data. Given this potential weakness, we investigate whether our new results are robust to changes in estimation method, measures of regulations, specification and sample size, as well as to the exclusion of outliers.

Given the limited variance of the job security variables, it is interesting to compare our fixed effects coefficients with the results obtained from estimating our main equation using random effects (RE; see table 13). We reject the hypothesis of consistency of the RE estimator for employment in the joint sample at 10 percent. The most substantial difference is the considerably smaller magnitude of the coefficient on indemnities for the OECD sample in the RE model. While in the OECD sample we still find a negative effect of indemnities on employment and a positive effect on unemployment, these effects are no longer statistically significant at conventional levels. The coefficient on advance notice is now positive and statistically significant in the employment regressions and negative and statistically significant in the unemployment regressions. The size and significance of the social security contribution coefficients are robust to the change in method of estimation.

In unreported results available upon request, we also examine whether our results are robust to alternative measurements of the cost of regulations that do not require assumptions about discount or layoff rates. Following Lazear (1990), we measure job security regulations as the mandatory amount (in multiples of monthly wages) that should be paid to a worker who is dismissed after ten years of tenure. A major disadvantage of this measure is that it only reflects job security in one point of the job security tenure schedule. In our samples, both his measure and our measure yield similar results.

29. We are greatly indebted to David Bravo and Sergio Urzua, who made us aware that adding Chile to the original sample used in Heckman and Pagés (2000) substantially changes our earlier conclusions.

*Notes:* See table 8 for explanations of abbreviations. Robust standard errors in parentheses. Columns (1) and (4) include a dummy variable that identifies the region, and which takes the value equal to 1 if the country is in Latin America and zero otherwise. PPP = purchasing power parity US\$ adjusted; LAC = Latin American and Caribbean.

\*\*\*Significant at the 1 percent level.

\*\*Significant at the 5 percent level.

We also assess the sensitivity of our results to the inclusion or exclusion of additional control variables such as year effects, region-specific year effects, time trends, and region-specific time trends. The results on the effect of social security contributions on employment and unemployment are very robust to changes in specification. Other results are less robust. For instance, in a specification with region-specific year-fixed effects, the coefficient on seniority pay is still positive, but it is no longer statistically significant at conventional levels. Adding or deleting either growth rates or GDP levels does not change our conclusions.

Important differences also arise when we assess the sensitivity of our baseline results to changes in sample size. In particular, we find that both

the coefficients on advance notice provisions and indemnities for dismissal are sensitive to the inclusion/exclusion of some countries in the sample, while the coefficients on social security payments and seniority pay do not change. For instance, excluding Germany from the sample greatly increases the coefficient on advance notice in the baseline employment specification. Similarly, excluding Brazil or Peru changes the coefficient on indemnities for dismissal in the employment regressions.

Finally, we check whether our results are robust to the exclusion of outliers, which are defined as those observations for which the difference in the regression coefficient when the  $i$ th observation is included and when it is not, scaling the difference by the estimated standard error of the coefficient, is larger than  $2/\sqrt{n}$  (Belsley, Kuh, and Welsch 1980). Our results confirm that there are no outliers that alter the coefficients for social security contributions. There are a few outliers that modify the coefficients on job security provisions (advance notice, indemnities, and seniority pay). However, they do not qualitatively alter our baseline results.

Taken as a whole, our results suggest that the negative (and statistically significant) association between social security contributions and employment, as well as a positive association between social security contributions and unemployment, is very robust to changes in estimation method, specification, regional sample, sample size, and outliers. The coefficients on our job security measures are much less robust. Thus, while the fixed effect (FE) estimates provide some evidence that in some OECD countries reducing indemnities results in higher employment rates, the evidence across countries provided by our RE estimates is less conclusive. One component of job security, seniority pay, is positively correlated with employment.

### 1.5.5 Endogeneity

It is often argued that labor reforms are put in place when labor market performance is poor. As demonstrated in the figure 3 plots, this is sometimes true for reforms in the LAC region. If a decline in employment rates (and an increase in unemployment rates) prompts a reduction in labor market regulations, then least squares estimates will be upward biased, potentially underestimating a negative relationship between job security or social security taxes and employment. Our baseline specification partly controls for the possibility of such reverse causality because the propensity for reform is partly captured by changes in the GDP or demographic conditions. Another source of concern is the timing of reforms. If labor reforms that liberalize the labor market are undertaken at particularly bad times, an estimated negative relationship between employment and regulations could just be the consequence of mean reversion.

In the results available on request, we address these issues in various ways. First, we attempt to control for differences in the propensity to reform at different points in time by including current and past GDP rates up

**Table 14** Correlation between Dependency Ratio and Social Security Contributions

	Social Security Payments (EPV)		
	Total	OECD	Latin America
Dependency ratio	112.10 (14.65)***	102.38 (14.97)***	283.6 (133.30)***
Country fixed effects?	Yes	Yes	Yes
<i>N</i>	514	411	86
<i>R</i> <sup>2</sup>	0.09	0.09	0.46

*Notes:* Dependency ratio computed as the ratio of the population 65 and older to the working age population (15–64). Robust standard errors in parentheses.

\*\*\*Significant at the 1 percent level.

to five lags. Because, presumably, bad employment outcomes are strongly associated with poor GDP outcomes, the inclusion of this set of variables will control for the propensity to reform. Second, we control for the timing of reforms by interacting changes in regulatory variables with a variable that measures the distance (in years) between the current year and the last business-cycle trough. Finally, we directly address the problem of reverse causality by using the dependency ratio, defined as the ratio of the population aged sixty-five and older to the population in the working age (fifteen to sixty-four), as an instrument for social security contributions.<sup>30</sup> Our results suggest that controlling for either the propensity or the timing of reforms does not alter the conclusions of our analysis.<sup>31</sup>

Regarding our instrumental variable estimates, table 14 indicates that in the three samples considered, social security contributions increase with the dependency ratio. The average dependency ratio in our sample is 0.17, while OECD and LAC are 0.19 and 0.08, respectively. The coefficients in table 14 suggest that if the dependency ratio increases in 1 percentage point, expected discounted social security contributions increase in 1.12 months for the total sample, 1.02 for the OECD, and 2.83 for Latin America. Moreover, our instrumental variable estimates (table 15) suggest that there is a causal relation between changes in social security contributions and changes in employment and unemployment rates, at least in the overall and OECD sample. In these two samples, IV estimates produce larger coefficients than the FE regressions. Instead, the Latin America IV esti-

30. The source of this data is the United Nations Population Statistics (United Nations Population Fund 1988).

31. Another way to control for endogeneity is to use the information in the figure 3 sequence to break out episodes of reform that were not preceded by major downturns (or upturns) of the economy from other episodes and analyze the latter. The problem with this approach in our sample is that it uses up too many scarce degrees of freedom.

**Table 15** Instrumental Variable Estimates

	Employment			Unemployment		
	Total	OECD	Latin America	Total	OECD	Latin America
AN	26.66 (16.26)	23.77 (13.51)	30.77 (24.61)	-15.72 (11.29)	-15.10 (10.01)	-12.73 (19.86)
ID	-1.08 (2.31)	-7.15 (2.38)***	2.33 (3.71)	1.73 (1.68)	5.80 (1.94)***	-1.64 (2.29)

*Notes:* All regressions include country fixed effects as well as GDP per capita (PPP adjusted), GDP growth, and the share of workers in working age population between twenty-five and fifty-four and fifty-five and sixty-four. We instrument Social Security contributions (measures in EPV) with the dependency ratio, computed as the ratio of the population sixty-five and older to the working age population (fifteen–sixty-four). Robust standard errors in parentheses. See table 8 for explanations of abbreviations.

\*\*\*Significant at the 1 percent level.

\*Significant at the 10 percent level.

mates yield coefficients with opposite signs to the ones obtained with the FE regressions. However, such coefficients are not statistically significant. The small number of observations available for Latin America is not sufficient to obtain precise IV estimates in this region.

### 1.5.6 Summary

Our analysis of pooled time series cross sections of countries underscores why the studies examining the impact of regulations in OECD countries based on such data have produced such ambiguous results. Lack of variation in the relevant policy measures and poor measures of regulation have hampered empirical analyses of the effect of regulations on labor market outcomes. To surmount these problems, we have expanded the number of countries comprising the LAC region, included more within-country variation, and improved the measures of regulation. Contrary to previously reported estimates, we have found little evidence of a systematic relationship between advance notice and indemnities for dismissal on employment or unemployment in our improved and expanded sample for Latin America. Estimates vary across countries, with some countries showing gains in employment after reducing job security and others showing little benefit to the employment rate or even employment reductions after such reforms, but no clear pattern emerges from the aggregates.

However, we find robust evidence that social security contributions are not fully shifted to workers. Payroll taxation tends to reduce employment and increase unemployment rates across samples and specifications. At the aggregate level, our analyses of reforms intended to increase the link between contributions and payments show mixed results.

## **1.6 Conclusions and Directions for Future Research**

Summarizing an entire school of thought, Freeman (2000, 3) writes that “the institutional organization of the labor market has identifiable large effects on distribution, but modest hard-to-uncover effects on efficiency.” This view is shared by many economists. However, the microevidence summarized in this volume suggests that mandated benefits and job security regulations have a substantial allocative impact both in Latin America and in OECD countries.

What policy lessons can be drawn from the essays in this volume? The evidence assembled in this volume suggests that labor market regulations are an inequality-increasing mechanism, because some workers benefit while many others are hurt. The benefits of programs funded with mandatory payroll contributions should be weighed against their costs in terms of employment. Funding such programs with general revenues does not necessarily reduce employment costs (see Nickell 1997), but strengthening the link between payments and benefits contributes to shifting the cost of such programs to workers, at least in the long run. Regulation acts unevenly across different groups in society. Young, uneducated, and rural workers are much less likely to enjoy coverage than older, skilled, and urban workers.

While the aggregate evidence on the effects of job security on the level of employment is inconclusive, the microstudies assembled here find a large and negative effect of job security on employment. Individual country studies based on microdata reduce the fragility and lack of robustness problems that pervade the cross section of countries’ time series literature.

### **1.6.1 Lessons For Future Research**

While these essays demonstrate that firms and workers respond to incentives in predictable ways and that regulation reduces employment and labor market turnover, more precise quantitative estimates would be desirable. We conclude with a discussion of the main areas in which future research could improve upon the current estimates.

#### *Incidence of Payroll Taxes and General Equilibrium*

Several essays in this volume take significant steps toward addressing whether workers accept lower wages if they receive mandated benefits. These estimates of incidence can be improved. Comparing the wages of covered and uncovered sectors to see if covered workers get lower wages, as

in Cárdenas and Bernal (chap. 4 in this volume) and several other essays in this volume, fails to control for self-selection into these sectors, which several studies in this volume have documented to be important. The method fails to adjust for general equilibrium effects arising from induced entry and exit and the willingness of workers to purchase benefits by accepting reduced wages.

The most comprehensive approach to the incidence question is the analysis of Marrufo (2001), which finds that controlling for self-selection and accounting for general equilibrium effects substantially affects estimates of tax incidence, and difference-in-differences estimates understate the true extent of wage adjustment. As argued by Kugler, the simple difference-in-differences method is downward biased so that the estimates reported in this volume are conservative.

#### *Dynamic Labor Demand*

The empirical models of labor demand estimated by the authors in this volume are traditional static models and dynamic labor demand models based on the assumption of symmetric adjustment costs. They abstract from the asymmetries in labor demand that are produced by severance and indemnity systems. Appendix B sketches out the main ideas in the asymmetric demand literature using a two-period model. Alonso-Borrego and Aguirregabiria (1999) develop the econometrics needed to estimate such models, but the methods remain to be implemented on LAC data. Given that all of the labor demand models estimated in this book assume symmetric adjustment costs, it would be productive to rework these studies using more advanced methods. As previously noted, the inconclusive evidence on the effect of job security on firm adjustment dynamics may be an artifact of the symmetry assumption.

In this class of models, it would also be useful to account for general equilibrium effects of entry and exit of firms. Hopenhayn and Rogerson (1993) demonstrate that, in principle, accounting for general equilibrium effects can reverse the predictions of partial equilibrium models.

#### *Accounting for Nonstationarity*

All of the duration models used to determine the impacts of regulation on labor market turnover assume stationary environments. Any student of Latin America knows how poor that assumption is. The high volatility of economic outcomes in Latin America suggests that this assumption does not adequately characterize the region. Accounting for nonstationarity more systematically would improve econometric estimates of behavioral parameters for the region.

#### *Accounting for the Effects of Regulation on Output*

All of the labor demand studies estimate output-constant wage elasticities. Abstracting from the potentially important econometric problem of

endogeneity of output, output-constant demand functions are more robust because they allow the analyst to abstract from product market adjustments to relative price changes. At the firm level, the output-constant effects of regulation understate the total effect of regulation if regulation raises the marginal cost of labor to the firm and costs cannot be shifted onto wages or other factor costs. The estimates reported here underestimate the full disemployment effects of deregulation in sectors adversely impacted. At the level of the national economy, the effects are more ambiguous because the burden of regulation may impact industries differently although it will still have efficiency losses by distorting sectoral allocations. In a closed economy, relative output prices adjust and will lead to an expansion of output in those sectors least impacted. So in those sectors, greater regulation may lead to greater employment. In an open economy facing world prices, when regulations are not accommodated by a downward adjustment of factor prices, regulation reduces output and accentuates reductions in employment.

A complete analysis of the impact of regulation would require accounting for both product market and factor market adjustments. The presumption is that a full account would produce disemployment effect of regulation on the overall economy, but not necessarily in each sector.

Notice, however, that even if wages adjust fully and there are no adverse effects of regulation on labor demand, regulation may still have substantial effects on the welfare of workers. If a job security mandate is offset by lower wages, worker welfare is not necessarily improved, at least not for all workers. It may be higher or lower depending on how much the mandate differs from what workers and firms would mutually agree upon in an unregulated environment.

#### *Accounting for Serial Correlation*

While most of the studies summarized in this volume measure the cost of regulations by elaborating direct monetary measures of their cost to employers, several authors use the length of the lag (the speed of adjustment) as an alternative measure of the cost of regulation facing the firm. The intuition supporting this is based on the original work of Holt et al. (1960), as previously described in section I.4.2.

In the simple model of equations (2) and (3), if we introduce an error term and an implicit theory of optimal employment as a function of the real wage,  $W_t$ , we obtain

$$(4) \quad n_t^* = a + bW_t + \varepsilon_t, \quad b \leq 0.$$

If  $\varepsilon_t$  is serially correlated, we obtain

$$(5) \quad \varepsilon_t = \rho\varepsilon_{t-1} + u_t,$$

where  $u_t$  has zero mean and is independently and identically distributed, and  $\rho$  is the first-order serial correlation. Analysts obtain a high estimated

value of  $\lambda$  (the coefficient on lagged labor) from a least squares estimation that does not correct for serial correlation because

$$(6) \quad n_t = (1 - \lambda)(a + bW_t) + \lambda n_{t-1} + (1 - \lambda)\varepsilon_t.$$

If  $1 < \lambda < 1$  and  $\rho > 0$ , ordinary least squares (OLS) estimates of  $\lambda$  are upward biased. An asymptotically unbiased estimator that accounts for this serial correlation is based on

$$(7) \quad n_t = (1 - \lambda)(1 - \rho)a + (1 - \lambda)b(W_t - \rho W_{t-1}) + (\lambda + \rho)n_{t-1} - \lambda \rho n_{t-2} \\ + (1 - \lambda)u_t,$$

which is derived from equation (6) by lagging it one period, solving for  $(1 - \lambda)\varepsilon_{t-1}$ , writing  $\varepsilon_t = \rho\varepsilon_{t-1} + u_t$  in equation (6) and substituting for  $\varepsilon_{t-1}$ . This bias is especially important in making cross-country comparisons where serial correlation coefficients may differ greatly across economies. For studies of regulations in a single country, this bias will not affect estimates of the relative cost of different reforms if the serial correlation pattern is invariant across reforms. However, no meaning can be attached to the absolute value of the lag coefficient.

This conventional model assumes symmetric hiring and firing costs. Yet even in the original Holt et al. (1960) study, this assumption was only introduced as a mathematically simplifying one that was contrary to their evidence. A more accurate description of the data from Latin America and other regions is that there are substantial asymmetric adjustment costs.

A measurement model accounting for asymmetric adjustment costs requires a new econometric approach. In work available on request, we consider a model of asymmetric hiring and firing costs based on Hopenhayn and Rogerson (1993). The coefficient on lagged labor is not necessarily monotonic in the cost of labor regulations. This may account for the ambiguous evidence on the impact of regulation on the cost of adjustment obtained from the conventional estimates.<sup>32</sup>

## 1.6.2 Taking Stock

Although there is clearly room for improvement, the body of evidence summarized in this chapter and reported in this book demonstrates that regulation matters, that the choice of labor market institutions matters, and that further labor reforms offer the promise of promoting both efficiency and equity across demographic groups in Latin America. They demonstrate the power of microdata to answer important questions when the evidence from cross-country macro time series is ambiguous.

32. The intuition behind this result is simple. Different serial correlation-fixed cost pairs produce the same lagged employment coefficient. This is also possible in the simple model (6). So it is possible that a regime with higher labor transition costs is also one with lower serial correlation in shocks and so would display a lower estimated lag and a faster adjustment rate. See Barbarino and Heckman (2003).

## Appendix A

### *Definitions and Sources of Variables Used in Section I.5*

For the empirical analysis described in section I.5, we build an unbalanced panel data covering the period 1983–1999. Table A.3 describes the variables and their sources. Table A.4 describes the countries and the years covered in our sample.

#### **Computation of Labor Market Regulation Measures**

##### Advance Notice and Indemnities for Dismissal

###### *OECD Countries*

We gather information on advance notice and indemnities for dismissal for OECD countries from the OECD *Employment Outlook* table 2.A.2, “Required Notice and Severance Pay for Individual Dismissal” (1999, 94–96), which summarizes the “case of a regular employee with tenure beyond any trial period, dismissed on personal grounds or economic redundancy but without fault.” For countries in which it is likely for individual dismissals to be considered “unjust” (measured as those countries to which the OECD gives a score of 2 or more in a 1–3 scale in table 2.A.4, 100)—that is, countries where a “transfer and or retraining to adapt to different work must be attempted prior to dismissal” and where “worker capability cannot be ground for dismissal”—we consider the information summarized in the table entitled “Compensation and Related Remedies Following Unjustified Dismissal.” From this table we see that, for this subset of countries, in at least one country unjust dismissals carry a much higher penalty. This is the case of Spain. We make this contingency explicit by computing the expected severance pay by assigning a 1/2 probability that a dismissal will be considered unfair and will carry the higher severance pay that the law mandates in this event. We obtain information on labor reforms from table 2.1 (OECD 1999, 53), which describes the main changes in legislation since the mid-1980s. We also compare the information described in OECD (1999) with that presented in Grubb and Wells (1993). If they diverge, we take the information in the latter to be valid up to 1993, while we take the information presented in OECD (1999) to be valid from 1997 onward. For the years in between, the index has a missing value. There are only four countries where there are some divergences between the former and the latter source. This is the case of Denmark, Greece, Netherlands, and Sweden. Finally, in countries where the law prescribes different severance pay and advance notice for blue- and white-collar workers, we compute the cost of dismissal as the unweighted average for the two groups. For Hungary, Ko-

rea, New Zealand, and Turkey, the job security measures only take non-missing values from 1990 onward because we could not find legal information for former years. To construct our index, we do not consider upper monetary limits. In addition, we do not consider benefits that firms pay or unions can obtain for their workers that exceed the legal mandatory. Finally, we do not consider what workers can get in courts if they sue their employers.

The following are individual country notes. In Australia, we consider the severance pay awarded to workers dismissed for redundancy. For Canada, we take the maximum of the severance pay and advance notice mandated by the federal and the local jurisdiction. In Greece, for white-collar workers, advance notice can be waived if full severance pay is given. We thereby assume that firms pay in full to avoid paying additional advance notice. In Ireland, the awarded severance pay depends on the age of the worker. We assume that workers receive 0.18 monthly wages per year worked, which corresponds to the (unweighted) average of half of one week per year worked (workers under the age of forty-one) and one week per year worked (workers over the age of forty-one). In Norway, after ten years of tenure, notice period increases with age. To capture this effect, we have increased notice period from three months to four and five in the case of individuals of more than fifteen years of tenure. For Spain, we adjust the severance pay obtained in case of just dismissal by the fact that many dismissals are considered unjust. We therefore weigh mandatory dismissals in case of just and unjust causes by a probability of 1/2 for each event.

### *Latin America*

We consider the legal information, summarized in tables A.1 and A.2, obtained from the Ministries of Labor of individual countries.

In Brazil, employers are required to deposit 8 percent of a workers' wage in individual workers' accounts, which accrue interest rates. In case of a firm initiated dismissal, firms are required to pay a worker severance pay that is a given fraction,  $\varphi$ , of what a worker owns in his individual account. The 1988 constitutional reform increased this share from 0.1 to 0.4 of the total amount in the fund. To compute the fraction of what is accrued in the individual fund, we assume that the interest rate equals the discount rate. Therefore, the indemnity is computed as

$$\text{Indemnities} = \sum_{i=1}^T \delta^{i-1} (1 - \delta)(i) \cdot \varphi,$$

where  $i$  denotes tenure at the firm,  $\delta$  is the per period probability of survival (equal to 0.88), and  $T$  denotes the maximum tenure of a worker in a firm, which is assumed to be equal to twenty. In Honduras, Jamaica, Nicaragua, and Dominican Republic, a constant advance notice equal to one month is assumed. In Peru, there were reforms in job security in 1991, 1995, and

Table A.1 Legislation Concerning Termination of Indefinite Contracts in 1987 and 1999

Country	Date of Reform	Advance Notice		Seniority Premium		Compensation if worker quits?

Trinidad and Tobago	None	2 months		0	0	0	0
Uruguay	None	0	No changes	$x \cdot N$	No changes	0	0
Venezuela	1997	1/4–3 months	No changes	$x \cdot N$	$2x \cdot N$	$x \cdot N$	$2x \cdot N$

Source: Ministries of Labor in Latin America and the Caribbean.

Notes: FUND: A certain fraction of a worker's wage is deposit in an individual account every month. The principal plus the interest can be withdrawn by the worker upon dismissal and in some cases, upon voluntary separation.  $x$  = monthly wages;  $N$  = years of tenure;  $r$  = interest rate of fund.

<sup>a</sup>Workers can choose between getting an unconditional payment after seven years in the firm, or getting a higher indemnity in case of dismissal. Most workers opt for the latter.

Table A.2 Legislation Concerning Indemnities for Dismissal in 1987 and 1999

Country	Date of Reform	Compensation for Dismissal Due to Economic Reasons		To whom do the reforms apply?	Upper limit to compensation for dismissal?	
		1987	1999		1987	1999

Notes: FUND: A certain fraction of a workers' wage is deposit in an individual account every month. The principal plus the interest can be withdrawn by the worker upon dismissal and in some cases, upon voluntary separation.

1996. Tables A.1 and A.2 only report the schedule as in 1990 and in 1999. See Saavedra and Torero (chap. 2 in this volume) for a more detailed description of the changes in the Peruvian labor code throughout the 1990s.

### Seniority Pay

Seniority payments only exist in Latin America. There are two kinds. In Brazil, Colombia, Ecuador, and Peru, workers deposit 1/12 of their monthly wages in individual accounts. In this case, seniority pay is computed as

$$\text{SenP} = \sum_{i=0}^T \beta^i,$$

where  $T = 20$ . This reflects the discounted value of a stream of payments equivalent to one month of pay per year. For Colombia, Kugler (chap. 3 in this volume) reports that before the 1990 labor reform, workers were entitled to one month of salary per year of work as a seniority fund upon separation independent of the cause of separation. However, partial withdrawals were allowed and deducted in nominal terms from the final payment, implying a “double retroactivity” with an estimated cost of 35 percent of the total payments of seniority pay in the manufacturing sector. We therefore apply a surcharge of 35 percent to the legislated schedule for seniority pay during the period before 1990.

Instead, in Venezuela and Panama, labor codes mandate a mandatory seniority payment that is computed as multiples of the last wage per year of work. In those cases, seniority pay is computed as

$$\text{SenP} = \sum_{i=1}^T \delta^{i-1} (1 - \delta) (\alpha_j \cdot i),$$

where  $\alpha_j$  denotes multiples of the last wage, and  $i$  denotes tenure at the firm. In Venezuela, the legal codes specified a seniority pay of one monthly wage per year of work ( $\alpha_j = 1$ ). After the 1997, seniority pay was increased to two monthly wages per year of work ( $\alpha_j = 2$ ). Notice that this formula assumes that the probability of worker turnover is identical to the probability of job turnover. Because, in general, worker turnover rates tend to be higher than job turnover rates, we also experimented with a probability of worker turnover equal to two times and three times the probability of job turnover. The cost of seniority pay declines with the rate of turnover (because the probability of surviving in the firm and obtaining larger amounts declines). Our estimated results are robust to different assumptions in the worker turnover rate.

### Social Security Regulations

Information provided by *Social Security Programs Throughout the World* (United States Social Security Administration 1983–1999). Social

Table A.3 Definitions and Sources of Variables Used in Section 5

Variable	Source	Description
Employment/Population	OECD Statistics and Household Surveys Data from Latin America	OECD: Employment to population. Data refers to people 15 and over, but in some countries, data refers to people who are between 15 and 66 (Denmark), 15 and 74 (Finland, Hungary), 16 and 17 (Iceland, Norway), 16 and 64 (Sweden), or 16 and older (Spain, United Kingdom, United States). See the methodological notes of labor force statistics at <a href="http://www.oecd.org">www.oecd.org</a> . National and/or European Labour Force Surveys are the main source for the Labor Force Statistics database. Latin America: Computed directly from Household Survey Data for the countries, years and sources listed in table A.4. Employment to population rate for workers 15–65. Are considered employed all workers that declared having a job in the week of reference. It also includes unpaid workers. National data except in Argentina, Bolivia, and Uruguay.
Unemployment	OECD Statistics and Household Surveys Data from Latin America	OECD: Unemployment rate of people 15–64. National and/or European Labour Force Surveys are the main source for the Labor Market Statistics indicator (LMSI) database, OECD. Latin America: Percent of the labor force 15–65 that did not work in the period of reference but are actively looking for a job. National data except in Argentina, Bolivia, and Uruguay.
GDP growth	World Bank Development Indicators (2001)	Annual percentage growth rate of GDP at market prices based on constant local currency. Aggregates are based on constant 1995 U.S. dollars. GDP measures the total output of goods and services for final use occurring within the domestic territory of a given country, regardless of the allocation to domestic and foreign claims.

GDP per capita, PPP (current international \$)	World Bank Development Indicators (2001)	GDP per capita based on purchasing power parity (PPP). GDP PPP is gross domestic product converted to international dollars using purchasing power parity rates. An international dollar has the same purchasing power over GDP as the U.S. dollar in the United States. GDP measures the total output of goods and services for final use occurring within the domestic territory of a given country, regardless of the allocation to domestic and foreign claims.
Share of WAP 25–54	United Nations Population Fund (1998)	Share of working age population 15 to 64 that are between 25 to 54 years old
Share of WAP 55–64	United Nations Population Fund (1998)	Share of working age population 15 to 64 that are 55 or older
Advance notice (AN)	Own construction	Expected discounted cost of providing mandatory AN measured in multiples of monthly wages
Indemnities for dismissal (ID)	Own construction	Expected discounted cost of providing mandatory ID measured in multiples of monthly wages
Seniority pay (SenP)	Own construction	Expected discounted cost of providing SenP measured in multiples of monthly wages
Social Security contributions (SSC)	Own construction	Expected discounted cost of providing mandatory advance notice measured in multiples of monthly wages
Social Security contributions (ss)	U.S. Social Security Administration (1983–1999)	Per period cost of SSC measures as a percent of monthly wages

Notes: See table 8 (col. [1]). Number of observations = 417.

security contributions include contributions by employers and employees to old age, disability and death, sickness and maternity, work injury, unemployment insurance, and family allowances programs. Because this information is only available biannually, we extend the data to yearly frequency in two alternative ways—by interpolating or by inputting each missing data value with the value in the former year. The results of our empirical analysis do not vary with the method used. The results also do not vary when we consider only the original biannual data.

For Argentina, we obtained direct information from the country. Rates apply to Buenos Aires. In all countries, we consider the rates applied to wage earners. We do not include contributions made by the government to fund social security programs. In cases where contributions differ across individuals, states, or industry risk, only one rate is chosen, and the choice varies somewhat across countries. However, the same criterion is used within countries across time. This somewhat reduces cross-country comparability but preserves across time comparability within countries.

### Social Security Reform

The variable Reform takes a value of 1 after a country has implemented a social security reform that totally or partially replaces a pay-as-you-go system by an individual capitalization system. Based on social security reforms information summarized in Lora and Pagés (2000), this variable takes the value of 1 in Chile on and after 1981, in Colombia on and after 1994, in Argentina on and after 1994, in Uruguay on and after 1996, in Mexico and Bolivia on and after 1997, and in El Salvador on and after 1998.

## Appendix B

### *Dynamic Demand Specifications*

All of the papers on labor demand in this volume ignore the asymmetric nature of labor adjustment costs. In this appendix, we explore the consequences of this asymmetry on labor demand. The main conclusion is that static and dynamic costs of labor have separate effects on labor demand, and in general no scalar index adequately summarizes these costs. In order to specify labor demand functions in the presence of asymmetric hiring and firing costs, it is convenient to use a two-period model. Such a model is implicit in Kugler (chap. 3 in this volume). Let  $f(\ell)$  denote output as a function of labor input  $\ell$ . Let  $\theta$  be a second period productivity shock. It is

We thank Jagadeesh Sivadasan for helpful comments on this appendix.

normalized against a first-period productivity shock of 1. We assume, for simplicity, that workers do not quit once they are hired.

Labor hired in period one is  $\ell_1$ . Labor employed in period two is  $\ell_2 = \ell_1 + \Delta$ .  $\Delta$  is thus the change in the stock of period-one labor. Spot wage  $W$  is assumed to be common in both periods, and is assumed to be exogenous to the firm. The cost of firing a worker is  $C$ . Offsetting this cost is the saving in wages. The cost of hiring a worker is the wage. Asymmetry arises when  $C \neq 0$ . Assume no discounting. Labor  $\ell_1$  is kept on in period two unless second-period demand shocks ( $\theta$ ) are sufficiently low. The firm maximizes profits

$$(B1) \quad f(\ell_1) - W\ell_1 + E[\theta f(\ell_1 + \Delta) - W(\ell_1 + \Delta) - C \text{Max}(-\Delta, 0)],$$

where the first-period labor productivity is normalized to 1.

We assume that the support of  $\theta$  is  $(0, \infty)$  and that  $\theta$  is an (absolutely continuous) random variable. If  $\theta \geq 1$  with probability 1, the firm in the second period wants  $\Delta \geq 0$ . Labor productivity has increased when  $\theta$  is bigger than its first-period value, which implicitly is set at 1.

The presence of second-period firing costs inhibits hiring in the first period. Thus, anticipating the possibility of an adverse shock in the second period, the firm hires less labor than it would hire in the first period in the absence of firing costs. If, for the sake of making an heuristic argument, we characterize the firm as myopically maximizing period-by-period profits, the firm acts as if the first-period productivity shock is less than 1 in making its first-period decisions and hires less labor than it would if there were no second-period firing costs. Letting  $\bar{\theta}$  be the value of the ‘‘as if’’ first-period productivity shock, if  $\theta > \bar{\theta}$  in period two, then  $\theta f'(\ell_2) = W$  and  $\ell_2 = [f']^{-1}(W/\theta) > \ell_1$ .

If  $\theta = \bar{\theta}$ , the firm stays put at  $\ell_1$  so that  $\ell_1 = \ell_2$  and  $\Delta = 0$ . If productivity is below  $\bar{\theta}$ , the firm may still keep its workforce at  $\ell_1 = \ell_2$  because it is costly to fire labor. We now determine the lower bound on  $\theta$  that gives rise to inaction. For a fixed  $\ell_1$ , the two required conditions for inaction ( $\Delta = 0$ ) are  $\theta f'(\ell_1) < W$ , so it pays in gross terms to get rid of a unit of  $\ell_1$ , and  $\theta f'(\ell_1) > W - C$ , so it does not pay in net terms. Thus the inequalities determining the zone of inaction are (for a given  $\ell_1$ )

$$W - C \leq \theta f'(\ell_1) \leq W.$$

The lower boundary  $\theta^*$  is  $(W - C)/(f'(\ell_1)) = \theta^*$ . Holding  $\ell_1$  fixed, raising  $C$  lowers the threshold  $\theta^*$ . Thus the zone of inaction for a given  $(\ell_1, C)$  is  $\theta^* \leq \theta \leq \bar{\theta}$ , where  $\bar{\theta} = W/(f'(\ell_1))$ .

The first order condition for  $\ell_1$  is  $f'(\ell_1) - W + E(\theta f'(\ell_1 + \Delta) - W) = 0$ , where  $\Delta = 0$  if  $\theta^* \leq \theta \leq \bar{\theta}$ ,  $\Delta < 0$  if  $\theta < \theta^*$ , and  $\Delta > 0$  if  $\theta > \bar{\theta}$ . From concavity,  $\ell_1$  is decreasing in cost  $C$ . Intuitively, firms with high firing costs hold back on hiring  $\ell_1$ . There is an option value of holding back on hiring

$\ell_1$  to avoid the cost of firing unwanted second-period labor. In order to characterize  $\ell_1$ , we must first characterize  $\Delta(\ell_1)$ .

### Second-Period (Conditional on $\ell_1$ ) Demand Functions

Letting  $\Delta^-$  denote the reduction in the stock of labor and  $\Delta^+$  be the expansion of such stock, we obtain the first-order condition for  $\Delta^-$  as

$$\theta f'(\ell_1 + \Delta^-) = W - C$$

or

$$\ell_1 + \Delta^- = (f')^{-1}\left(\frac{W - C}{\theta}\right).$$

Take  $\ell_1$  as given. Observe that if  $0 < \theta < \theta^*$ ,  $\Delta < 0$ . Define  $\varphi \equiv f'^{-1}$ . Observe that from concavity  $\varphi' < 0$ . Then

$$\ell_1 + \Delta^- = \varphi\left(\frac{W - C}{\theta}\right).$$

Observe that at  $\theta = \theta^*$ ,  $\Delta^- = 0$ . If  $\theta > \bar{\theta}$ ,  $\theta f'(\ell_1 + \Delta^+) = W$  and  $(\ell_1 + \Delta^+) = \varphi(W/\theta)$ . If  $\theta^* < \theta < \bar{\theta}$ , the firm operates at  $\ell_1$  and  $\Delta = 0$ . If  $\theta < \theta^*$ ,  $\theta f'(\ell_1 + \Delta^-) = W - C$  and  $\ell_1 + \Delta^- = \varphi[(W - C)/\theta]$ . Define  $g(\theta)$  as the density of  $\theta$ . Given  $\ell_1$ , expected demand in period two (averaged over the  $\theta$  states) is, for a given firm,

$$E(\ell_2 | W, C, \ell_1) = \int_0^{\theta^*} \varphi\left(\frac{W - C}{\theta}\right) g(\theta) d\theta + \ell_1 \int_{\theta^*}^{\bar{\theta}} g(\theta) d\theta + \int_{\bar{\theta}}^{\infty} \varphi\left(\frac{W}{\theta}\right) g(\theta) d\theta.$$

Thus

$$\begin{aligned} \frac{\partial E(\ell_2 | W, C, \ell_1)}{\partial W} &= \frac{\partial \theta^*}{\partial W} \varphi\left(\frac{W - C}{\theta^*}\right) g(\theta^*) + \int_0^{\theta^*} \frac{1}{\theta} \varphi'\left(\frac{W - C}{\theta^*}\right) g(\theta) d\theta \\ &\quad + \int_{\bar{\theta}}^{\infty} \left(\frac{1}{\theta}\right) \varphi'\left(\frac{W}{\theta}\right) g(\theta) d\theta + \ell_1 \left[ \frac{\partial \bar{\theta}}{\partial W} g(\bar{\theta}) - \frac{\partial \theta^*}{\partial W} g(\theta^*) \right] \\ &\quad - \left( \frac{\partial \bar{\theta}}{\partial W} \right) \varphi\left(\frac{W}{\bar{\theta}}\right) g(\bar{\theta}), \\ \frac{\partial E(\ell_2 | W, C, \ell_1)}{\partial C} &= \left( \frac{\partial \theta^*}{\partial C} \right) \varphi\left(\frac{W - C}{\theta^*}\right) g(\theta^*) - \int_0^{\theta^*} \frac{1}{\theta} \varphi'\left(\frac{W - C}{\theta}\right) g(\theta) d\theta \\ &\quad + \ell_1 \left[ \frac{\partial \bar{\theta}}{\partial C} g(\bar{\theta}) - \frac{\partial \theta^*}{\partial C} g(\theta^*) \right] - \frac{\partial \bar{\theta}}{\partial C} \varphi\left(\frac{W}{\bar{\theta}}\right) g(\bar{\theta}). \end{aligned}$$

Using the demand function,  $\varphi[(W - C)/\theta^*] = \ell_1$ , and  $\varphi(W/\bar{\theta}) = \ell_1$ ,

$$\frac{\partial E(\ell_2 | W, C, \ell_1)}{\partial W} = \int_0^{\theta^*} \frac{1}{\theta} \varphi'\left(\frac{W - C}{\theta}\right) g(\theta) d\theta + \int_{\bar{\theta}}^{\infty} \frac{1}{\theta} \varphi'\left(\frac{W}{\theta}\right) g(\theta) d\theta < 0,$$

and

$$\frac{\partial E(\ell_2 | W, C, \ell_1)}{\partial C} = -\int_0^{\theta^*} \frac{1}{\theta} \phi' \left( \frac{W}{\theta} \right) g(\theta) d\theta > 0.$$

The positivity of this final expression arises from the fact that as  $C$  increases, the firm is more risk averse ( $\theta^*$  falls) so that it is more likely that it hires labor in the second period.

If  $\theta$  is iid across firms in period 2, and independently and identically distributed (i.i.d.) across time, then the mean conditional (on  $\ell_1$ ) labor demand function is not a direct function of  $W + \Pr(0 < \theta < \theta^*)C$ , which, in this simple framework, is the measure of labor cost used in Heckman and Pagés (2000) and in the empirical analysis of section I.5. In fact, the model predicts that

$$\frac{\partial E(\ell_2 | W, C, \ell_1)}{\partial W} + \frac{\partial E(\ell_2 | W, C, \ell_1)}{\partial C} < 0$$

so that  $\partial E(\ell_2 | W, C, \ell_1) / \partial W$  is larger in absolute value than  $\partial E(\ell_2 | W, C, \ell_1) / \partial C$ , although they are of opposite signs.

This analysis suggests that empirical specifications of labor demand functions should use  $C$  and  $W$  separately.  $W$  corresponds to static costs as defined in the text.  $C$  corresponds to costs of adjustment. The OLS regressions of conditional (on  $\ell_1$ ) demand functions do not identify the standard substitution terms used in static demand analysis.

One way to avoid problems with direct estimation of labor demand functions is to estimate production functions. These can be used to derive the demand functions given fixed costs without directly estimating demand functions with fixed costs.

### First-Period Demand Functions

These are obtained by substituting each state-contingent  $\ell_2 = \ell_1 + \Delta$  demand function into expression (B1) and maximizing with respect to  $\ell_1$ . As in the analysis of the second period demand function,  $W + \Pr(0 < \theta < \theta^*)C$  is not an appropriate marginal price in any state. Substituting into expression (B1) and making the dependence of  $\Delta^-$  and  $\Delta^+$  on  $W, C, \ell_1$  explicit, we obtain total profits (as perceived in the first period) as

$$\begin{aligned} & f(\ell_1) - W\ell_1 \\ & + \int_0^{\theta^*} \{ \theta f[\ell_1 + \Delta^-(W, C, \ell_1, \theta)] - (W - C)\Delta^-(W, C, \ell_1) - W\ell_1 \} g(\theta) d\theta \\ & + \int_{\theta^*}^{\bar{\theta}} [\theta f(\ell_1) - W\ell_1] g(\theta) d\theta \\ & + \int_{\bar{\theta}}^{\infty} \{ \theta f[\ell_1 + \Delta^+(W, C, \ell_1)] - W[\ell_1 + \Delta^+(W, C, \ell_1)] \} g(\theta) d\theta. \end{aligned}$$

Assuming an interior solution, and using the envelope theorem,

$$f'(\ell_1) - W + \int_0^{\theta^*} \{\theta f'[\ell_1 + \Delta^-(W, C, \ell_1, \theta)] - W\} g(\theta) d\theta \\ + \int_{\theta^*}^{\bar{\theta}} [\theta f'(\ell_1) - W] g(\theta) d\theta = 0,$$

so the first period demand obtained as the solution to this equation  $\ell$  is a function of  $W$  and  $C$  separately and not  $W + \Pr(0 < \theta \leq \theta^*)C$ . Observe, trivially, that the  $\ell_1$  obtained as a solution of this first-order condition is lower than the  $\ell_1$  obtained when  $C = 0$ . This rationalizes our choice of  $\bar{\theta} < 1$  in the heuristic solution outlined above.

Mandate-Based Health Reform and the Labor Market: Evidence from the Massachusetts Reform  
Jonathan T. Kolstad and Amanda E. Kowalski  
NBER Working Paper No. 17933  
March 2012  
JEL No. I11,I28

**ABSTRACT**

We model the labor market impact of the three key provisions of the recent Massachusetts and national “mandate-based” health reforms: individual and employer mandates and expansions in publicly-subsidized coverage. Using our model, we characterize the compensating differential for employer-sponsored health insurance (ESHI) -- the causal change in wages associated with gaining ESHI. We also characterize the welfare impact of the labor market distortion induced by health reform. We show that the welfare impact depends on a small number of “sufficient statistics” that can be recovered from labor market outcomes. Relying on the reform implemented in Massachusetts in 2006, we estimate the empirical analog of our model. We find that jobs with ESHI pay wages that are lower by an average of \$6,058 annually, indicating that the compensating differential for ESHI is only slightly smaller in magnitude than the average cost of ESHI to employers. Because the newly-insured in Massachusetts valued ESHI, they were willing to accept lower wages, and the deadweight loss of mandate-based health reform was less than 5% of what it would have been if the government had instead provided health insurance by levying a tax on wages.

# 1 Introduction

The 2010 United States national health reform and the 2006 Massachusetts state health reform both focus on expanding health insurance coverage to near-universal levels. These “mandate-based” reforms rely on three key provisions to expand coverage: a mandate that employers offer coverage or pay a penalty, a mandate that individuals obtain coverage or pay a penalty, and expansions in publicly-subsidized coverage. While regulatory policy has long relied on mandates (for example, command and control regulation of technologies to reduce pollution), public policies that mandate that individuals purchase privately-supplied goods have little precedent. As we demonstrate, mandate-based policy has the potential for greater efficiency in achieving policy goals if the individuals who gain insurance through their employers value the coverage that they receive.<sup>1</sup>

In this paper, we model and then estimate the relationship between ESHI and the labor market, allowing us to assess the impact of health reform on welfare. First, we extend the Summers (1989) model of a full-compliance employer mandate to incorporate the key features of the national and Massachusetts health reforms. Using this model, we characterize the compensating differential for ESHI — the causal change in wages associated with gaining ESHI — and we derive a set of sufficient statistics that capture the impact of the reforms on the labor market and on welfare. Although these sufficient statistics arise from a set of potentially complex and difficult-to-measure structural parameters that determine individual health insurance and labor supply decisions, we can recover them from easily measured changes in labor market outcomes. Our extensions of the Summers (1989) model incorporate more sources of variation in labor market outcomes, enriching the model’s empirical content. Furthermore, our extensions allow us to capture interactions between policy provisions. For example, Summers (1989) gives us the intuition that an employer mandate reduces deadweight loss relative to a tax, but that intuition does not hold if there is already an individual mandate in place.

Using variation induced by the Massachusetts health reform — which mirrors the national reform in all of the elements of our model — we estimate the empirical analog of our model. We first estimate the compensating differential for health insurance. Our empirical strategy relies on exogenous shifts into and out of ESHI induced by reform. Using longitudinal data on wages, employment, and hours worked, we study changes in labor market outcomes for individuals who switch to and from ESHI over the reform period. We incorporate variation between Massachusetts and other states to control for national trends, and we incorporate individual fixed effects to control for time-invariant attributes that determine an individual’s labor market outcomes. We also incorporate variation in firm size to allow some firms to be exempt from the employer mandate and to control for variation in the Massachusetts labor market that is unrelated to the reform. Combining all of these sources of variation and the reform allows us to obtain causal estimates of the compensating

---

<sup>1</sup>The question of whether the federal government can implement the individual mandate is the critical legal question that has led to court challenges of the national reform. Although the federal government’s authority to tax is not questioned, court challenges focus on its authority to mandate the purchase of a private good under the Commerce Clause. We do not comment on the constitutionality of the individual mandate. Rather, we inform the choice of policy instrument by focusing on the efficiency of mandate-based policy relative to traditional tax-based policy.

differential associated with health insurance.

Building on the estimated compensating differential for health insurance, we estimate the sufficient statistics that determine the welfare impact of health reform. Specifically, our model allows us to recover the cost of ESHI to employers, the underlying worker valuation of ESHI, the labor supply and demand elasticities, and the magnitude of the behavioral responses to the policy parameters of the Massachusetts reform (the employer and individual mandates and subsidies). Once we demonstrate that these parameters are sufficient statistics for welfare analysis, we use our estimates to compute the deadweight loss associated with the mandate-based insurance expansion in Massachusetts. We also compare our estimated deadweight loss to the deadweight loss of a counterfactual tax-based insurance expansion that would involve levying a wage tax to pay for the provision of health insurance directly.

We find a compensating differential for ESHI that is of the expected theoretical sign and slightly smaller in magnitude than the full cost of health insurance, suggesting high average valuation of the benefit among the newly-insured. Consistent with the large decline in wages, we find a small hours differential between jobs with and without ESHI, also suggesting high average valuation of the benefit among the newly insured. Apart from our theoretical contributions, our findings contribute to the empirical literature on the incidence of fringe benefits, with health insurance as the largest of those benefits. Typically, the endogeneity of fringe benefits and labor market outcomes leads researchers to find wrong-signed compensating differentials for fringe benefits (see Gruber (2000) and Currie and Madrian (1999) for reviews); most studies find that individuals who receive more fringe benefits also receive higher wages. Existing studies that do not find wrong-signed compensating differentials for health insurance rely on *incremental* changes in the cost of health insurance, such as premium increases due to the addition of mandated maternity benefits (Gruber (1994)) or increasing malpractice costs (Baicker and Chandra (2005)). By using variation from the Massachusetts reform, we find a compensating differential for the *full* cost of health insurance; individuals who receive ESHI receive wages that are lower by approximately the amount their employer spends on ESHI.

Translating our estimated compensating and hours differentials into sufficient statistics for welfare analysis, we find that mandate-based reform is a relatively efficient way to expand coverage. Our main estimate suggests that mandate-based coverage expansion in Massachusetts resulted in a deadweight loss due to distortion of the labor market that was only 5% of the distortion associated with instead providing health insurance through a tax on wages. We examine the robustness of our estimates to a variety of alternative specifications. Although our estimates vary, they always show that that mandate-based reform is substantially more efficient than tax-based reform because our finding that individuals value ESHI is very robust.

The paper proceeds as follows: Section 2 discusses the provisions of Massachusetts and national reforms that are likely to affect the labor market. Based on these provisions, Section 3 develops a theory of mandate-based health reform that we use to characterize the compensating differential for ESHI and the welfare impact of mandate-based health reform relative to tax-based health reform; Sections 4 and 5 discuss identification and estimation of the model. Section 6 introduces the data.

Section 7 presents results and discusses robustness, and Section 8 concludes.

## 2 Massachusetts Health Reform, the ACA, and the Labor Market

The Massachusetts health reform, passed in April 2006, and the federal Patient Protection and Affordable Care Act (the “ACA”), passed in March 2010, contain a number of similar provisions that are likely to affect the labor market. We provide a side-by-side comparison in Appendix A. First, both reforms include a “pay-or-play” employer mandate, which requires employers to offer health insurance or pay a penalty. Unlike traditional full-compliance mandates, pay-or-play mandates allow for noncompliance and an associated penalty. The Massachusetts reform requires employers with 11 or more full-time employees to offer their workers the option to purchase health insurance coverage. Health coverage options must, at minimum, include a plan that allows employees to purchase health insurance using pre-tax wages and employers must contribute at least 33% of the value of the premium or they will be assessed a penalty. This penalty is equal to \$295 per employee per year. Compliance has been high. Only approximately 4.6% of employers large enough to be subject to the penalty (0.5% of all employers) paid it from 2007 to 2010 (Massachusetts DHCFP (2011b)).<sup>2</sup>

The ACA incorporates a similar pay-or-play employer mandate, but it defines large employers as those with 50 or more full-time employees (Kaiser Family Foundation (2010a)). The ACA also requires that coverage options be affordable, such that the insurance offered pays at least 60% of covered expenses and the employee is not required to pay more than 9.5% of family income for individual coverage (Burkhauser et al. (2011)). If the employer does not offer options for coverage, the penalty assessed is \$2,000 per full-time employee, excluding the first 30 employees. If the options do not meet the definition of affordable, the employer must pay \$3,000 for any employees who enroll in insurance via an exchange and receive a tax credit, also excluding the first 30 employees (Kaiser Family Foundation (2010)).

The second keystone of both reforms is the individual mandate to purchase insurance. The Massachusetts health reform incorporated an individual mandate requiring nearly all residents to purchase health insurance deemed to meet or exceed a specific value (called “minimum creditable coverage”), or pay a penalty if they could have purchased affordable coverage but did not.<sup>3</sup> The penalty in Massachusetts for those who are unable to demonstrate they have coverage when they

<sup>2</sup>In addition, employers are subject to a separate “free rider surcharge” penalty if they do not offer a plan that allows employees to purchase health insurance using pre-tax wages and instead an employee receives care through the state’s uncompensated care pool. The compliance cost for employers to avoid this penalty is minimal — they need only set up a plan without contributing anything to it. Accordingly, zero employers were liable for the free rider surcharge in fiscal years 2008 and 2009 (Massachusetts DHCFP (2011a)).

<sup>3</sup>See Kaiser Family Foundation (2009) and Raymond (2007). Individuals are automatically exempt from the individual mandate penalty in Massachusetts if they have a gap in creditable coverage of three months or less in a given calendar year, if they claim a religious exemption, or if their annual income is under 150% of the Federal Poverty Level (effectively because the lowest cost Connector plan would be free for them). Other individuals can file for an exemption based on affordability using the Certificate of Exemption Application, which also provides details on the definition of “minimum creditable coverage.” (The application is available at <https://www.mahealthconnector.org/portal/binary/com.epicentric.contentmanagement.servlet.ContentDeliveryServlet/FindInsurance/Individual/Affordability2520Calculator/2011CertificateofExemption.pdf> accessed December 1, 2011.)

file their taxes is equal to 50% of the cost of the least generous (Bronze) plan available in the Massachusetts health insurance exchange (the Connector).<sup>4</sup> Compliance with the individual mandate in Massachusetts has been high — over 97% of tax filers submitted the tax form to comply with the individual mandate in 2008, and less than 2% reported any spell of uninsurance (Massachusetts Health Connector and Department of Revenue (2010)). The ACA has similar requirements, mandating that individuals purchase qualifying coverage or pay penalties, which will be phased in beginning in 2014. The ACA penalty is the higher of \$695 per uninsured member of the household (up to three) or 2.5% of household income.

The third cornerstone of both reforms is the establishment of subsidized coverage for those with incomes too high to qualify for fully subsidized Medicaid coverage. In Massachusetts, this coverage is offered by the state at no premium to those with incomes below 150% of the federal poverty level (FPL) (\$27,795 for a family of three in 2011).<sup>5</sup> Those earning less than 100% of FPL have access to traditional Medicaid (MassHealth) or fully subsidized CommCare, depending on categorical eligibility. Individuals between 100 and 150% of FPL receive CommCare coverage but do not pay a premium. Individuals between 150 and 300% of FPL (\$27,795 to \$55,590 for a family of three) can purchase coverage through the Connector (CommCare plans) with subsidies that decline with income. Similarly, the ACA expands Medicaid eligibility to all those with incomes below 133% of poverty (\$24,707 for a family of three).<sup>6</sup> It also extends subsidized coverage higher up the income distribution to 400% of poverty (\$74,120 for a family of three).

### 3 A Model of Mandate-Based Health Reform and the Labor Market

In this section, we incorporate the three key features of the ACA and the Massachusetts reform into a model of mandate-based health reform and the labor market. Using our model, we characterize the compensating differential for health insurance and the welfare impact of health reform. Our model extends the model pioneered by Summers (1989) (hereafter called the “Summers model”) and subsequently used by Gruber and Krueger (1991), Gruber (1994), Buchmueller et al. (2011), and Anand (2011), among others. Our extensions capture the salient features of the Massachusetts and national reforms that affect the labor market, bringing the model closer to actual policy. By taking all of the key features of the Massachusetts and national reforms into account, we enrich the empirical content of the model and contribute to the literature on the impact of health reform

---

<sup>4</sup>According to the Massachusetts Connector website in 2010, in the zip code 02138 (Cambridge, MA), the cost of a Bronze plan for a family in Cambridge with two 40-year-old parents was \$11,000 annually. For a couple with two individuals aged 35, the Bronze plan cost \$6,600 annually. A 31-year-old purchasing a Bronze would expect to pay \$2,868.

<sup>5</sup>In the 48 contiguous states and the District of Columbia, the 2011 poverty line is \$10,890 for a single individual, and it grows by \$3,820 for each additional family member (Federal Register (2011)).

<sup>6</sup>Effectively, eligibility will be extended to 138% of poverty because there is a special deduction of income under 5% of poverty (Kaiser Family Foundation (2010a)).

on the labor market.<sup>7</sup> These extensions also allow us to capture the interactions between policies yielding additional insight. Specifically, we explore the intuition that an employer mandate reduces deadweight loss relative to a tax and find that it does not hold if there is already an individual mandate in place.

### 3.1 The Model

We begin by characterizing labor supply and demand when some firms do and others do not provide ESHI. A representative firm sets wages to maximize profits, resulting in the following labor demand function:

$$L_D^t = L_D^{ESH I,t}(w + b)ESH I_t + L_D^{NoESH I,t}(w + \rho_t b)(1 - ESH I_t).$$

Willingness to demand hours of work  $L$  in period  $t$  is a function  $L_D^{ESH I,t}$  or  $L_D^{NoESH I,t}$  of the monetary hourly wage  $w$ , and other arguments, depending on an indicator for whether the firm provides health insurance  $ESH I_t$  at time  $t$ , which is exogenous for now.<sup>8</sup> If the firm provides health insurance, labor demand depends solely on the cost of employing an individual in dollar terms — wages and the dollar cost to the employer of a standard health insurance benefit  $b$ . If the firm does not provide health insurance, labor demand depends on the wage and the per-worker penalty  $\rho_t b$  for not complying with the employer mandate.

A representative individual chooses how many hours to work to maximize utility, resulting in the following labor supply function:

$$L_S^t = L_S^{ESH I,t}(w + \alpha b + \lambda_t b - \mu_{xt} b)ESH I_t + L_S^{NoESH I,t}(w)(1 - ESH I_t).$$

Willingness to supply hours of work  $L$  in period  $t$  is a function  $L_S^{ESH I,t}$  or  $L_S^{NoESH I,t}$  of the hourly wage  $w$ . For an individual with ESHI, given by the indicator  $ESH I_t$ , which is exogenous for now, labor supply is also a function of the cost to the employer for a standard health insurance benefit  $b$ , scaled by the amount that an individual values a dollar of ESHI relative to a dollar of wages,  $\alpha$ , and policy parameters in place at time  $t$ : the individual penalty for not having health insurance  $\lambda_t$ , and the subsidy  $\mu_{xt}$  available on the individual health insurance market, which varies in generosity based on income group  $x$ . In the individual's choice problem, several factors can affect the underlying valuation of ESHI relative to a dollar of wages  $\alpha$ . For example, canonical insurance theory demonstrates that willingness to pay for insurance is determined by an individual's wealth, health risk, risk preferences, and the available insurance contract (see Arrow (1963) and Rothschild and Stiglitz (1976)). Furthermore, there is a tax preference for ESHI, so we expect an individual's marginal tax rate to affect his willingness to pay for ESHI. Rather than modeling these factors individually, we model only  $\alpha$ , which is a sufficient statistic for welfare analysis in the spirit of

<sup>7</sup>Krueger and Kuziemko (2011) consider the implications of the ACA on coverage for the uninsured, Pohl (2011) considers the implications of the ACA for the labor supply of single mothers, and Heim and Lurie (2012) consider the implications of the Massachusetts reform for the self-employed.

<sup>8</sup>We develop the model relying on the simplifying assumption that we can measure  $L$  in hours of work, ignoring the potential difference between the extensive and intensive margin of employment. We relax this assumption in our empirical implementation.

Chetty (2009). If the worker values ESHI, he is willing to work for lower wages in a job that provides ESHI, and  $\alpha$  captures the full magnitude of the downward shift in the individual's supply curve in the absence of an individual penalty or a subsidy.

The individual penalty augments the individual's underlying valuation of ESHI, shifting his labor supply curve further downward — even if the individual does not value health insurance on its own merits, he will value it at least as much as the penalty that he must pay for not having it. We generally expect  $\alpha + \lambda \leq 1$ .<sup>9</sup> A subsidy, like the individual mandate, only affects an individual's labor supply if he does obtain health insurance through his employer. However, in the face of a penalty, he is more willing to work for ESHI instead of wages; in the face of a subsidy for health insurance outside of employment, he is less willing to work for ESHI instead of wages. In addition to examining the underlying valuation, the penalty, and the subsidy individually, we can capture the entire shift in the labor supply curve associated with ESHI. The resulting sum,  $\alpha + \lambda - \mu_x$ , which we call the “penalty-and-subsidy-inclusive valuation” is an important sufficient statistic for our analysis.

The inclusion of intertemporal variation (indexed by  $t$ ) in the model captures the impact of introducing health reform, allowing assessment of changes in policy as well as tying the model to the empirical setting. We model the impact of health reform by specifying two values of  $t$ : *Before* and *After*. The employer mandate, the individual mandate, and the subsidies are not in place before reform such that  $\rho_{Before} = \lambda_{Before} = \mu_{x,Before} = 0$ , but they are in place after reform such that  $\rho_{After} = \rho$ ,  $\lambda_{After} = \lambda$ , and  $\mu_{x,After} = \mu_x$ . The policy parameters of health reform are the only time-varying elements of the model.

Figure 1 depicts a graphical representation of the model, assuming that  $L_D^{ESHI,t}$  and  $L_D^{NoESHI,t}$  have the same linear functional form and that  $L_S^{ESHI,t}$  and  $L_S^{NoESHI,t}$  have the same linear functional form (the linear functional form is an approximation to a general nonlinear functional form). The labor market equilibrium  $(w, L)$  in period  $t$  is the intersection of labor supply and labor demand. There are two potential equilibria in each period  $t$ , conditional on whether the individual

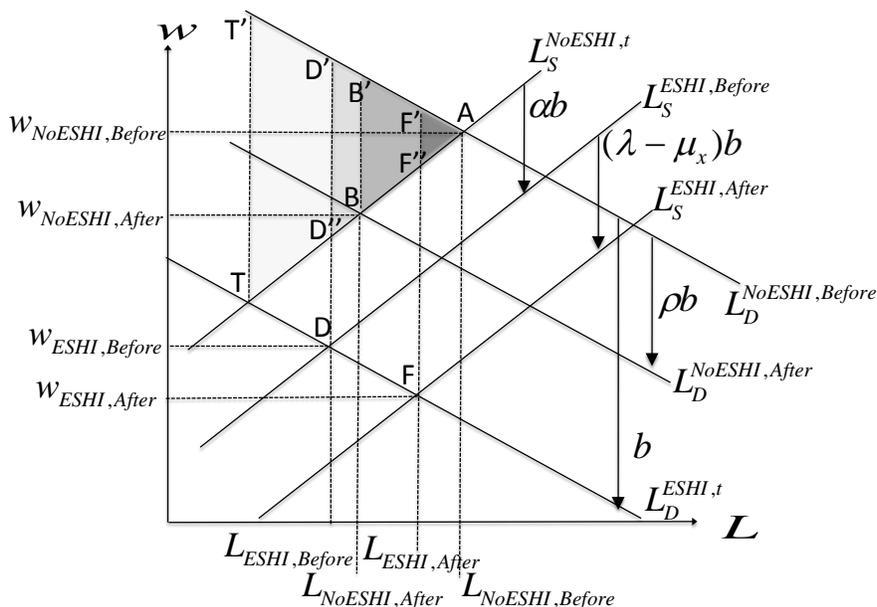

---

<sup>9</sup>We do not expect the individual penalty to increase the total valuation of health insurance for an individual who already values it fully. Therefore, we specify that the magnitude of  $\lambda$  is affected by the underlying valuation  $\alpha$  and the statutory penalty  $\Lambda$  as follows:

$$\lambda = \begin{cases} \Lambda, & \text{for } \alpha \leq 1 - \Lambda \\ 1 - \alpha, & \text{for } 1 - \Lambda \leq \alpha \leq 1 \\ 0, & \text{for } \alpha > 1 \end{cases}$$

In the first case,  $\alpha$  is small, so  $\lambda$  takes on its statutory value, and the penalty-inclusive valuation, which we define as  $\alpha + \lambda$ , is less than 1. In the second case,  $\lambda$  is large enough to augment  $\alpha$  until the penalty-inclusive valuation is full. In the third case, which we see as very unlikely, the individual's underlying valuation of health insurance is higher than the cost to the employer. Such a case could arise if an individual cannot access health insurance outside of employment, perhaps because of pre-existing conditions that are excluded on the individual market. Such a case could also arise if health insurance through the employer is cheaper than other insurance, which is likely because of the tax-preference for employer-sponsored health insurance and because employers have more negotiating power than individuals. In this case, the penalty-inclusive valuation of health insurance is his underlying valuation, and the penalty has no impact. We define the subsidy similarly so that it cannot reduce an individual's penalty-and-subsidy-inclusive valuation beyond zero.

Figure 1: Graphical Model

receives health insurance through the employer:  $D$  and  $A$  are the equilibria for individuals with and without ESHI before the reform, respectively;  $F$  and  $B$  are the equilibria for individuals with and without ESHI after the reform, respectively.

The Summers model is a special case of our model with only two equilibria and a different policy intervention. Before the policy intervention, there is only one equilibrium at  $A$  — no jobs include ESHI. The policy intervention consists of a mandate that all employers must provide health insurance, and it is not a pay-or-play mandate, so there is full compliance with the mandate. After the policy intervention, there is only one equilibrium at  $D$  — all jobs include ESHI.

### 3.2 Characterization of the Compensating Differential for ESHI

Using our model, we can characterize the compensating differential for health insurance, defined as the causal difference in wages between jobs with ESHI and jobs without ESHI. We can also characterize the corresponding hours differential using hours lieu of wages. We first characterize the compensating and hours differentials in terms of differences between labor market equilibria, and then we characterize them in terms of sufficient statistics.

The first panel of Table 1 presents the compensating differential for health insurance in terms of differences between equilibria in the first column and sufficient statistics in the third column. The second panel presents the analogous hours differential. These expressions follow directly from the geometry of Figure 1.<sup>10</sup> We represent the slope of the labor supply curve with  $s$  and the slope of the labor demand curve with  $d$  (these slopes become elasticities if we specify  $w$  as the logarithm

<sup>10</sup>To obtain the compensating and hours differentials before the reform, consider  $D'$ . Wages at  $D'$  are equal to  $w_D + b$ . Because  $D'$  and  $A$  are on the demand curve, we can express the slope of the demand curve as the difference in wages at these two points, divided by the difference in hours at these two points:

Table 1: Compensating and Hours Differentials

Compensating Differential	$t$	Sufficient Statistics	Coefficients
$w_D - w_A$	Before - Before	$\frac{s-\alpha d}{d-s} b$	$\beta_8 [ + \beta_{8e} ]$
$w_F - w_B$	After - After	$\frac{(1-\rho)s-(\alpha+\lambda-\mu_x)d}{d-s} b$	$\beta_1 + \beta_8 [ + \beta_{1e} + \beta_{8e} ]$
$w_D - w_B$	Before - After	$\frac{(1-\rho)s-\alpha d}{d-s} b$	$\beta_8 - \beta_{11} [ + \beta_{8e} ]$
$w_F - w_A$	After - Before	$\frac{s-(\alpha+\lambda-\mu_x)d}{d-s} b$	$\beta_1 + \beta_8 + \beta_{11} [ + \beta_{1e} + \beta_{8e} ]$
Hours Differential	$t$	Sufficient Statistics	Coefficients
$L_D - L_A$	Before - Before	$\frac{1-\alpha}{d-s} b$	$\gamma_8 [ + \gamma_{8e} ]$
$L_F - L_B$	After - After	$\frac{1-\rho-(\alpha+\lambda-\mu_x)}{d-s} b$	$\gamma_1 + \gamma_8 [ + \gamma_{1e} + \gamma_{8e} ]$
$L_D - L_B$	Before - After	$\frac{1-\rho-\alpha}{d-s} b$	$\gamma_8 - \gamma_{11} [ + \gamma_{8e} ]$
$L_F - L_A$	After - Before	$\frac{1-(\alpha+\lambda-\mu_x)}{d-s} b$	$\gamma_1 + \gamma_8 + \gamma_{11} [ + \gamma_{1e} + \gamma_{8e} ]$

of wages and  $h$  as the logarithm of hours).

The rows of each panel show different expressions for the compensating and hours differentials, depending on the timing of the comparison between individuals with ESHI and individuals without ESHI. The second column indicates the time periods being compared: the first row is the differential before the reform, the second is the differential after the reform, the third is the differential between those with ESHI before the reform and those without ESHI after the reform, and the fourth is the differential between those with ESHI after the reform and those without ESHI before reform. The differential before the reform is equivalent to the corresponding differential from the Summers model. It is a special case of the other three expressions with the policy parameters set to zero. Analysis of the impact of health reform on the labor market, however, requires the policy parameters. We will be particularly interested in the compensating differential for those who switch from not having ESHI before the reform to having it after the reform. For those individuals, shown in the expression in the last row of the each panel, if the penalty-and-subsidy-inclusive valuation is full ( $\alpha + \lambda - \mu_x = 1$ ), then the absolute value of the compensating differential is equal to the amount of the benefit (ESHI decreases wages by  $b$ ), and the hours differential is zero (ESHI does not distort hours worked).

Given the expressions in Table 1, we can use the compensating and hours differentials for those who switch to ESHI after reform to learn about the valuation of ESHI. If the compensating differential is equal to the cost of the benefit and the hours differential is zero, then we can infer that the penalty-and-subsidy-inclusive valuation is full. Previous studies based on the Summers

$$d = \frac{(w_D + b - w_A)}{(L_D - L_A)}.$$

Next, consider a point directly below  $A$  on the  $L_s^{ESHI, Before}$  curve. We can express the slope of the supply curve as follows:

$$s = \frac{(w_D - (w_A - \alpha b))}{(L_D - L_A)}.$$

We obtain the compensating and hours differentials by solving this system of equations.

model have stopped at this point because they only have enough variation to identify the valuation if it is full. If the compensating differential is less than the cost of the benefit, and the hours differential is nonzero, then they cannot infer the magnitude of the penalty-and-subsidy-inclusive valuation beyond stating that it is not full. However, as we discuss in Section 4 on identification, the additional sources of variation in our model extend the empirical content of the Summers model, allowing us to identify the penalty-and-subsidy-inclusive valuation, regardless of the true magnitude.

### 3.3 Characterization of the Welfare Impact of Health Reform

Using our model, we can also derive the impact of health reform on employer and employee welfare. To do so, we first characterize the welfare impact of health reform in terms of sufficient statistics. We then express the sufficient statistics in terms of differences between labor market equilibria, showing that our key sufficient statistics for the welfare impact of health reform are functions of compensating and hours differentials.

#### 3.3.1 Sufficient Statistics for the Welfare Impact of Health Reform

Distortions to the labor market occur when workers are willing to work for wages lower than the market wage and employers are willing to hire workers for more than the market wage, but the transaction does not occur. Summing the area of the employer and employee surplus from the transactions that would have occurred in the absence of the policy, we can express the combined deadweight loss of the policies of mandate-based health reform  $m$  as follows:

$$DWL_m = \frac{b^2}{2(s-d)} ((1 - (\alpha + \lambda - \mu_x))^2 ESHI_{After} + \rho^2 (1 - ESHI_{After})). \quad (1)$$

If we know the values for all of the terms in this equation, we can calculate the welfare impact of mandate-based health reform. Thus, these terms are sufficient statistics for the welfare-impact of mandate-based health reform. Graphically, the welfare impact corresponds to a weighted combination of the two overlapping triangles shown in Figure 1. The deadweight loss is the triangle given by  $F'AF''$  if the representative individual has ESHI after the reform, and the deadweight loss is equal to the triangle given by  $B'AB$  if he does not. As shown, the deadweight loss for individuals without ESHI is smaller, but the relative magnitudes of the triangles can reverse, depending on the magnitudes of the policy parameters. If the employer penalty is equal to zero and the full cost of ESHI and the penalty-and-subsidy-inclusive valuation is full ( $\alpha + \lambda - \mu_x = 1$ ), then there is no deadweight loss associated with health reform.

Using this expression, we can compare the deadweight loss of mandate-based reform to the deadweight loss of alternative policies. This approach can be applied to a comparison of any policy, provided we can express the key policy elements in terms of labor market equilibria. We focus on comparison of the deadweight loss from mandate-based reform to the deadweight loss from a tax-based reform that relies on a wage tax to finance a single payer or “Medicare for all” program. The

is the relevant welfare comparison if the government has already decided to expand health insurance coverage — as in the case of Massachusetts and the ACA — and is looking for the most efficient way to do so. To compare these policy options, we begin by computing the deadweight loss of a tax. Suppose that before the tax-based reform, there are no penalties or subsidies. No employers provide health insurance to their employees, such that the initial labor market equilibrium is a point  $A$ . Now suppose that the government levies a tax  $\tau$  on employers to provide health insurance (the incidence is the same if the government instead levies the tax on employees). Suppose for now that the tax is equal to the cost of providing a standard health insurance benefit  $b$ . As shown in Figure 1, labor demand shifts downward by  $b$ , and holding labor supply constant, the new labor market equilibrium is at point  $T$ . Following Summers (1989), the key assumption about tax-based reform is that it does not induce a shift in labor supply. The deadweight loss of the tax-based reform is the shaded region given by the triangle  $T'AT$ :

$$DWL_{\tau} = \frac{\tau^2}{2(s-d)}.$$

Taking the ratio of the deadweight loss of mandate-based reform to the deadweight loss of tax-based reform, allowing  $b \neq \tau$  gives:

$$\frac{DWL_m}{DWL_{\tau}} = \frac{b^2}{\tau^2} ((1 - (\alpha + \lambda - \mu_x))^2 ESHI_{After} + \rho^2 (1 - ESHI_{After})). \quad (2)$$

This equation characterizes the welfare of the combined features of mandate-based reform relative to a tax-based reform in terms of a small number of sufficient statistics: the cost  $b$  that employers pay for ESHI compared to the necessary tax revenue  $\tau$  for the same benefit; the penalty-and-subsidy-inclusive valuation,  $\alpha + \lambda - \mu_x$ , for individuals who have ESHI after reform; the employer penalty  $\rho$  for individuals who do not have ESHI after reform; and the fraction of individuals with ESHI after reform,  $ESHI_{After}$ . Since the same individuals would be covered by both mandate-based and tax-based reform, underlying health risk is invariant to the plan. Thus the ratio of  $b$  and  $t$  is just the relative loading cost of ESHI and government-provided health insurance.

Welfare in the Summers model is a special case of welfare in our model. We can capture the ratio of the full-compliance mandate in the Summers model to a tax using equation (2) with no penalties or subsidies ( $\lambda = \mu_x = 0$ ), and all agents in ESHI after reform ( $ESHI_{After} = 1$ ). We can represent the deadweight loss of the full-compliance mandate with a single triangle,  $D'AD''$ , which is smaller than the triangle associated with a tax if  $\alpha > 0$ . This special case yields the theoretical contribution of Summers (1989): an employer mandate reduces deadweight loss relative to a tax.

However, the addition of an employer mandate does not always reduce deadweight loss relative to a tax. If there is already a pay-or-play individual mandate in place, the addition of a full-compliance or a pay-or-play employer mandate weakly decreases welfare. Consider the case where there is already an individual pay-or-play mandate in place, but there is no employer penalty. The deadweight loss is given by equation (1) with  $\mu_x = \rho = 0$ . Because there is no employer penalty, there is no distortion if the individual does not have ESHI. Adding a full-compliance

mandate weakly increases the deadweight loss because the individual must have ESHI and the associated distortion; zero distortion without ESHI is no longer possible. Likewise, adding a pay-or-play mandate weakly increases the deadweight loss because the individual now has a distortion associated with a positive  $\rho$  if he does not have ESHI. Our analysis demonstrates that it is important to consider the interactions between policies when assessing welfare.

### 3.3.2 Sufficient Statistics in Terms of Labor Market Equilibria

Building on the compensating and hours differentials, we can express most of the sufficient statistics in equations (1) and (2) in terms of differences in wages and hours between the four labor market equilibria depicted in Figure 1. Our derivation follows directly from the geometry of the figure. For example, we compute the slope of the labor supply curve by comparing equilibrium  $A$  to equilibrium  $B$ , and we compute the slope of the labor demand curve by comparing equilibrium  $D$  to equilibrium  $F$ , as shown in the first two rows of Table 2. In the subsequent rows of the table, we express all other sufficient statistics in terms of the slope of the labor supply and demand curves as well as differences between the equilibria.

Table 2: Sufficient Statistics

Sufficient statistics	Wages and Hours	Coefficients
$s$	$\frac{w_B - w_A}{L_B - L_A}$	$\frac{\beta_{11}}{\gamma_{11}}$
$d$	$\frac{w_F - w_D}{L_F - L_D}$	$\frac{\beta_1 + \beta_{11} [+ \beta_{1e}]}{\gamma_1 + \gamma_{11} + [\gamma_{1e}]}$
$\rho$	$\frac{d(L_B - L_A) - (w_B - w_A)}{b}$	$\frac{d(\gamma_{11}) - (\beta_{11})}{b}$
$b$	$d(L_F - L_A) - (w_F - w_A)$	$d(\gamma_1 + \gamma_8 + \gamma_{11} + [\gamma_{1e} + \gamma_{8e}]) - (\beta_1 + \beta_8 + \beta_{11} [+ \beta_{1e} + \beta_{8e}])$
$\alpha$	$\frac{s(L_D - L_A) - (w_D - w_A)}{b}$	$\frac{s(\gamma_8 [+ \gamma_{8e}]) - (\beta_8 [+ \beta_{8e}])}{b}$
$\lambda - \mu_x$	$\frac{s(L_F - L_D) - (w_F - w_D)}{b}$	$\frac{s(\gamma_1 + \gamma_{11} [+ \gamma_{1e}]) - (\beta_1 + \beta_{11} [+ \beta_{1e}])}{b}$
$\alpha + \lambda - \mu_x$	$\frac{s(L_F - L_A) - (w_F - w_A)}{b}$	$\frac{s(\gamma_1 + \gamma_8 + \gamma_{11} [+ \gamma_{1e} + \gamma_{8e}]) - (\beta_1 + \beta_8 + \beta_{11} [+ \beta_{1e} + \beta_{8e}])}{b}$

We can characterize the entire welfare impact of health reform given by equations (1) and (2) with these sufficient statistics and two others: a value for  $ESHI_{After}$ , and a ratio of  $b$  to  $t$ . From the table, we see that two of the key sufficient statistics — the cost of the benefit  $b$  and the penalty-and-subsidy-inclusive valuation  $\alpha + \lambda - \mu_x$  — are functions of the compensating and hours differentials from before to after the reform.

## 4 Identification

In this section, we develop the empirical analog of our model. In the previous section, we have shown that we can express the compensating differential for ESHI and the welfare impact of health reform in terms of differences between the four labor market equilibria in our model. In this section,

we first discuss how we can use the Massachusetts reform to identify the differences between the equilibria empirically. We then discuss the implications for identification of the compensating differential and the welfare impact of health reform.

#### 4.1 Identifying Differences Between Labor Market Equilibria

We can use the Massachusetts reform to identify the differences between labor market equilibria. The simplest approach would require only eight data points from within Massachusetts: average wages and hours for jobs with and without ESHI before and after reform. We could use these data points to plot the four labor market equilibria depicted in Figure 1. We could then calculate the compensating differential for ESHI and the sufficient statistics for the welfare impact of health reform given in Table 2.

However, additional sources of variation are available, and incorporating them into the model can be valuable in two respects. First, we can identify the differences between labor market equilibria more convincingly, given empirical considerations that are as yet outside our model. Second, we can choose to identify more labor market equilibria. Consider the sources of variation that allow us to identify the differences between labor market equilibria more convincingly. We incorporate variation between Massachusetts and other states to control for factors that shift labor supply and demand nationally for reasons that are unrelated to Massachusetts health reform. We also incorporate variation within individuals over time to control for a myriad of worker characteristics that shift labor supply and demand for a given individual for reasons that are unrelated to Massachusetts health reform.

In addition, we incorporate variation between small and large firms to control for Massachusetts-specific factors that could shift labor supply and demand after the reform in Massachusetts, but that are unrelated to health reform. Because small firms are exempt from the employer mandate, small firms that do not provide health insurance should not shift their labor demand from before to after the reform, and equilibrium  $B$  should correspond with equilibrium  $A$ . To the extent that equilibrium  $B$  does not coincide with equilibrium  $A$  for small firms, there could be Massachusetts-specific factors that affect the labor market differentially after the reform that are not due to the reform itself. Given empirical evidence, we control for these factors in our preferred specification.

Finally, we incorporate variation in subsidy amounts to identify more labor market equilibria. This variation allows us to identify separate equilibria for individuals for different subsidy amounts. With these equilibria, we can separately identify  $\lambda$  from  $\mu_x$ , and we can identify a different value of  $\mu_x$  for each income eligibility group  $x$ . However, because using this variation requires us to divide the data into small groups based on income eligibility thresholds, we do not use this variation in our primary specification. We extend the model to incorporate variation in subsidy amounts and discuss the associated results in Online Appendix OA1.

For convenience, when we refer in our notation and discussion to a specific equilibrium, we are referring to that equilibrium after netting out differences with the control groups. For example, when we refer to the ESHI equilibrium after the reform (equilibrium F), we imply that we have

already netted out the difference between Massachusetts and other states, the difference within individuals over time, and in our preferred specification, the difference by firm size.

## 4.2 Identification of the Compensating Differential for ESHI

Recall that Table 1 expressed the compensating and hours differentials as differences between labor market equilibria. Therefore, because we can identify differences between labor market equilibria we also identify the compensating and hours differentials. However, identification of some differences between labor market equilibria comes from more plausibly exogenous variation, implying that we identify some differentials more convincingly than others.

The most convincing identification comes from changes in ESHI status for a given individual induced by the reform. Less convincing are the first two differentials in Table 1 that rely on changes in ESHI status for a given individual *within* the period either before or after reform. The changes in ESHI status that identify these compensating differentials could be endogenous if individuals gain ESHI when they get a better job that includes health insurance. Empirically, consistent with the existing literature, we do not find negative compensating differentials using variation that does not rely on the reform, even after incorporating individual fixed effects, suggesting that ESHI switches that are not due to reform could be endogenous (Gruber (2000) and Currie and Madrian (1999)). However, the reform provides a source of exogenous variation in ESHI status that we can use to identify the differentials in the last two rows of Table 1. We can identify the compensating and hours differentials between equilibrium  $D$  and equilibrium  $B$  using individuals who switch out of ESHI from before to after the reform because they become eligible for subsidies on the individual market. However, subsidies only affect individuals with certain incomes, and all other individuals will have an incentive to switch into ESHI because of the individual and employer mandates. Therefore, the last compensating and hours differentials in Table 1, which compare equilibrium  $F$  and equilibrium  $A$ , will be the best identified.

## 4.3 Identification of the Welfare Impact of Health Reform

If the differences between the labor market equilibria are identified, we can calculate the sufficient statistics using the expressions in Table 2. However, as discussed above, some differences between labor market equilibria are identified more convincingly than others. Therefore, some sufficient statistics are identified more convincingly than others. Specifically, the sufficient statistics that can be derived from a labor market equilibrium before the reform and another labor market equilibrium after the reform with a different ESHI status are the best-identified. Fortunately, these sufficient statistics are the most important for welfare analysis.

From Table 2, we see that we can identify the penalty-and-subsidy-inclusive valuation  $\alpha + \lambda - \mu_x$  and the cost of the benefit  $b$  using individuals who transition from not having ESHI before the reform to having ESHI after the reform (equilibrium  $A$  to equilibrium  $F$ ) and values for  $d$  and  $s$ . The differences between these two equilibria are our best-identified measures of the compensating and hours differentials. Therefore, the penalty-and-subsidy-inclusive valuation and the cost of the

benefit will be the best-identified sufficient statistics.

The other sufficient statistics are identified, but not as convincingly because they do not depend on changes in ESHI status induced by the reform. For example, we can identify the slope of the demand curve  $d$  by comparing individuals with ESHI before and after the reform; we can identify the slope of the supply curve  $s$  by comparing individuals without ESHI before and after the reform; and we can also identify the employer penalty  $\rho$  by comparing individuals without ESHI before and after reform, using a value for  $d$ . In practice, we estimate values for these parameters that do not accord well with values that we expect based on the literature and the empirical magnitude of the employer penalty. Given that these parameters are not convincingly identified and that their misspecification can affect the estimates of all the other sufficient statistics through the  $s$  and  $d$  terms in their derivations, we discard the empirical estimates and calibrate them. Reviewing the literature (for example Blundell and MaCurdy (1999); Hamermesh (1996)) suggests that reasonable magnitudes for labor supply and demand elasticities are 0.1 and -0.2 respectively. Because our primary specification is in levels (not logarithms) we convert these into slopes at the mean wage and hours. We also calibrate the employer penalty  $\rho$  such that the dollar value of the employer penalty  $\rho b$  is equal to the statutory penalty of \$295 per year.

Given that we calibrate some sufficient statistics, one might be tempted to calibrate most of our model using the statutory values of the policy parameters, rather than estimating any sufficient statistics. However, we prefer to estimate the sufficient statistics for several reasons. First, the individual's underlying valuation  $\alpha$  does not have a statutory value. Second, the behavioral response to the policy parameters might be smaller or larger than the statutory policy parameters because of interactions between them and the individual's underlying valuation (see footnote 9). Third, to the extent that we think the behavioral response to the policy parameter should be equal to the statutory value, we can compare the two values in an over identification test.

Because of difficulties with separate identification, we rely mostly on the parameters or sums of parameters that are best-identified:  $b$  and  $\alpha + \lambda - \mu_x$ . As shown, we can characterize the entire welfare impact of health reform given by equations (1) and (2) with these sufficient statistics and two others: a value for  $ESHI_{After}$ , which we estimate, and a ratio of  $b$  to  $t$ , which we can calibrate. However, separate estimates of  $\alpha$ ,  $\lambda$ , and  $\mu_x$  would allow us to analyze the welfare impact of the separate components of health reform independently, so we proceed in estimating them, keeping in mind that our identification poses challenges.

As shown in Table 2, identification of  $\alpha$  requires a value for  $s$  and the comparison of people with and without ESHI before reform. The inclusion of individual fixed effects should help to identify  $\alpha$  because we control for time-invariant factors that affect wages and benefits. However, any changes over time that affect both simultaneously will lead to bias. For example, if an individual without health insurance gets promoted to a job with higher wages and ESHI, we will estimate a negative value for  $\alpha$ , even if the individual values the benefit such that the true value of  $\alpha$  is positive. Such bias is precisely the problem that has hindered previous effort to identify compensating differentials, particularly the compensating differential for entire cost of ESHI. Our identification for the penalty-and-subsidy-inclusive valuation is compelling relative to our identification of  $\alpha$ , illustrating the

advantage of our approach over the existing literature.

We are similarly interested in separate estimates for  $\lambda$  and  $\mu_x$ . As shown in Table 2, identification of the difference  $\lambda - \mu_x$  requires a value for  $s$  and the comparison of people with ESHI before and after reform. To separately identify  $\mu_x$  from  $\lambda$ , and to identify different values of  $\mu_x$  for people eligible for different subsidy amounts, we can incorporate variation in subsidy amounts across income eligibility thresholds as we discuss in Online Appendix OA1.

## 5 Estimation

To estimate all of the relevant differences between labor market equilibria and sufficient statistics that we use to estimate the compensating and hours differentials and the welfare impact of health reform, we specify and estimate wage and hours equations of the following form:

$$\begin{aligned}
 Y_{it} = & [\beta_1 MA * ESHI * After * Large + \beta_8 MA * ESHI * Large + \beta_{11} MA * After * Large + \\
 & \beta_{12} ESHI * After * Large + \beta_{19} ESHI * Large + \beta_{22} After * Large + \\
 & \beta_{23} Large + \phi_g * Large + ] \\
 & \beta_{1[e]} MA * ESHI * After + \beta_{8[e]} MA * ESHI + \beta_{11[e]} MA * After + \\
 & \beta_{12[e]} ESHI * After + \beta_{19[e]} ESHI + \beta_{22[e]} After + \phi_s + \delta_i + \varepsilon_{it}, \tag{3}
 \end{aligned}$$

where  $Y_{it}$  measures wages  $w$  or hours  $L$  for individual  $i$  at time  $t$ . In our main specifications, we specify wages and hours in levels. The level specification allows us to capture the impact of the reform on the intensive margin of how many hours to work and the extensive margin of whether to work because we can include unemployed workers in the sample, specifying that they have wages and hours of zero. We also investigate robustness to specifying wages and hours in logarithmic form.  $MA$  is an indicator for the state of Massachusetts relative to other states,  $ESHI$  is an indicator for ESHI relative to the absence of ESHI,  $After$  is an indicator for the period after the reform relative to the period before the reform, and  $Large$  is an indicator for large firms or firms of unknown size relative to small firms that are exempt from the employer mandate. We begin with a baseline specification that excludes all bracketed terms, which reflect variation between large and small (exempt) firms with  $e$  coefficient subscripts. We include the bracketed terms in our preferred specification. We represent the coefficients of the wage equation with subscripted  $\beta$  coefficients, and we represent the corresponding coefficients of the hours equation with subscripted  $\gamma$  coefficients. The numbers of the coefficients convey that they are a subset of the coefficients of the full equation that we use to separately identify different values of  $\mu_x$ , which we present in Online Appendix OA1. We include state fixed effects  $\phi_s$ , with a state other than Massachusetts omitted, to control for differences in wages across states, and we include individual fixed effects  $\delta_i$ , to control for time-invariant differences across individuals, allowing for individual-specific shocks at time  $t$ ,  $\varepsilon_{it}$ . We include a time fixed effect  $After$  to control for changes in the labor market over time, and we convert all wages into 2006 dollars using the Consumer Price Index for all urban consumers

(CPI-U) to adjust for inflation. We do not include time fixed effects at a greater level of detail in our main specification because the calculation of our sufficient statistics requires a single period before reform and a single period after reform. In all specifications, we also allow for a “during” implementation period that is separate from the before and after periods.<sup>11</sup>

Our estimating equations are so simple that we can estimate them with ordinary least squares. The simplicity of the estimating equations is an advantage of our model relative to alternative structural models because robustness analysis is easier to implement, and the results are more transparent. Furthermore, because the functional form of these equations is relatively simple, we can interpret the coefficients directly as well as the combinations of coefficients that make up the sufficient statistics.

Although our estimating equations resemble differences-in-differences models, such models are typically used to identify a single coefficient after netting out differences with control groups. In our case, however, we are interested in identifying the four labor market equilibria of our model, from which we derive the compensating and hours differentials and the sufficient statistics for welfare analysis. To obtain the four labor market equilibria of our model, we combine several coefficients from the wage and hours equations, making our analysis richer than traditional difference-in-differences analysis.

### 5.1 Estimating the Compensating Differential for ESHI

The first step in estimating the compensating differential for ESHI is to express the four labor market equilibria of our model in terms of coefficients from the estimating equations. We express the wages associated with each equilibrium in Table 3. We can express the hours associated with each equilibrium with  $\gamma$  in place of  $\beta$ . We normalize  $w_A = 0$  and  $L_A = 0$  so that all equilibria are relative to the equilibrium without ESHI before reform. The derivation of these expressions is straightforward. For example, the difference in wages between equilibrium  $B$  and  $A$  (the equilibrium without ESHI after the reform relative to the equilibrium without ESHI before the reform) is  $\beta_{11}$ , the change in wages from after the reform to before the reform for individuals who remain without ESHI in Massachusetts, relative to individuals in other states who remain without ESHI over the reform period. In the preferred specification, which includes the bracketed terms in equation (3),  $\beta_{11}$  also reflects the difference between individuals in large firms and individuals in small exempt firms, thus controlling for Massachusetts-specific factors after reform.

Table 3: Wages in Terms of Coefficients

$w_A$	NoESHI, Before	0
$w_B$	NoESHI, After	$\beta_{11}$
$w_D$	ESHI, Before	$\beta_8 [ + \beta_{8e} ]$
$w_F$	ESHI, After	$\beta_1 + \beta_8 + \beta_{11} [ + \beta_{1e} + \beta_{8e} ]$

<sup>11</sup>To simplify exposition, we omit the terms that correspond to the during period from equation (3). In all of our models, we include a term for the during period that corresponds to each term for the after period. We represent the coefficients on during period terms with corresponding  $d$  superscripts.

The next step in estimation of the compensating differential for ESHI is to express the compensating differentials in terms of coefficients. The last column of Table 1 expresses the compensating and hours differentials in terms of coefficients, which we can replace with estimated coefficients.

Our preferred measure of the compensating differential,  $w_F - w_A$ , is the sum of several coefficients:  $\beta_1 + \beta_8 + \beta_{11}$  [ $+\beta_{1e} + \beta_{8e}$ ]. These coefficients reflect the change in wages observed for individuals who switch from not having ESHI before the reform to having it after the reform, relative to individuals who have the same switch in ESHI status from before to after reform in other states. The coefficients in the preferred specification also control for Massachusetts-specific wage changes after reform using variation by firm size.

If there were no employer penalty ( $\rho = 0$ ), we could simplify our preferred estimate of the compensating differential to  $\beta_1$  [ $+\beta_{1e}$ ]. The employer penalty reduces potential sources of identification for the compensating differential because it affects the labor market equilibrium for workers *without* ESHI after the reform in Massachusetts. If the only impact of the reform were to change the labor market equilibrium for workers with ESHI after the reform, which would be the case if there were no employer penalty, workers without ESHI after the reform could provide an additional control group for workers with ESHI after the reform. Thus, we could control for Massachusetts-specific shocks unrelated to health reform in Massachusetts that occur at the same time as the reform without having to incorporate variation in firm size. In that case, the specification without firm size interactions would simplify into a traditional difference-in-differences-in-differences specification in which  $\beta_1$  would reflect the compensating differential for ESHI. Instead of being part of the estimated compensating differential, the coefficient  $\beta_{11}$  would control for Massachusetts-specific shocks coincident with reform, and the coefficient  $\beta_8$  would control for time-invariant differences between individuals with ESHI and individuals without ESHI in Massachusetts relative to other states. The disadvantage of having an employer penalty of zero in terms of identification would be that we would no longer have any labor supply shifters, so we could not identify the slope of the labor supply curve  $s$ .

Because the Massachusetts reform included a positive statutory employer penalty, even though it was small relative to the cost of ESHI, we prefer the expression  $\beta_1 + \beta_8 + \beta_{11}$  [ $+\beta_{1e} + \beta_{8e}$ ] for the compensating differential. However, because the statutory employer penalty was small, the compensating differential could, in practice, be very similar to  $\beta_1$  [ $+\beta_{1e}$ ]. In the model without firm size interactions, as the employer penalty goes to zero,  $\beta_8$  and  $\beta_{11}$  should approach zero and  $\beta_1$  should approach the magnitude of the compensating differential. Thus, when we examine the coefficients of our model, we expect  $\beta_1$  to be large and negative, and we expect  $\beta_8$  and  $\beta_{11}$  to be close to zero. Further, we expect  $\beta_8$  to be negative because as we have shown in Table 3,  $\beta_8$  gives the position of equilibrium  $D$ , which according to our model, should be to the lower left of equilibrium  $A$ . We also expect  $\beta_{11}$  to be negative because we have shown that  $\beta_{11}$  gives the position of equilibrium  $B$ , which should also be to the lower left of equilibrium  $A$  if there is a positive penalty. If our estimated  $\beta_8$  is positive, we will not trust our identification of the compensating differential identified by  $w_D - w_A$ , and we will continue to prefer the expression for  $w_F - w_A$ . If our estimated  $\beta_{11}$  is positive, we will want to incorporate the firm size interactions

that control for Massachusetts-specific labor market changes coincident with reform.

## 5.2 Estimating the Welfare Impact of Health Reform

To estimate the welfare impact of health reform, the first step is to express the sufficient statistics in terms of coefficients. We have already expressed the sufficient statistics in terms of differences between labor market equilibria in the second column of Table 2 and the labor market equilibria in terms of coefficients in Table 3. Combining, we express the sufficient statistics in terms of coefficients in the third column of Table 2.

Next, we estimate the deadweight loss of mandate-based reform by replacing terms with their corresponding empirical estimates as follows:

$$DWL_m = \frac{\widehat{b}^2}{2(\widehat{s} - \widehat{d})} \left( (1 - (\alpha + \widehat{\lambda} - \mu_x))^2 E\widehat{SHI}_{After} + \widehat{\rho}^2 (1 - E\widehat{SHI}_{After}) \right). \quad (4)$$

We also estimate the ratio of the deadweight loss of mandate-based reform to the deadweight loss of tax-based reform as follows:

$$\frac{DWL_m}{DWL_\tau} = \left( \frac{\widehat{b}}{\tau} \right)^2 \left( (1 - (\alpha + \widehat{\lambda} - \mu_x))^2 E\widehat{SHI}_{After} + \widehat{\rho}^2 (1 - E\widehat{SHI}_{After}) \right), \quad (5)$$

where we use  $\widehat{\cdot}$  to denote the estimate that corresponds to each parameter. We obtain  $\alpha + \widehat{\lambda} - \mu_x$  and  $\widehat{b}$  by plugging the estimated values of the compensating and hours differentials and the calibrated values of  $\widehat{s}$  and  $\widehat{d}$  into Table 2. We calibrate  $\widehat{\rho}$  to reflect the statutory employer penalty in Massachusetts. For  $\widehat{b}/\tau$ , we assume that  $b = \tau$ . We later relax this assumption and assess robustness to assuming lower loading costs for health insurance provided through tax-based reform. The only remaining parameter is  $E\widehat{SHI}_{After}$ , which we estimate as the probability of having ESHI in Massachusetts after reform in our data.

## 6 Data, Summary Statistics, and Examination of Labor Market Trends before Reform

### 6.1 The Survey of Income and Program Participation

For our main analysis, we use the Survey of Income and Program Participation (SIPP), a nationally representative longitudinal survey covering households in the civilian non-institutionalized population.<sup>12</sup> Individuals selected into the SIPP sample are interviewed once every four months over a four-year panel, with each interview covering information about the previous four-month period,

<sup>12</sup>The SIPP is not designed to be representative within the state of Massachusetts; however, the SIPP is the best data available to us on other dimensions, so we proceed by focusing on within-individual variation. We have also run our main regressions in the restricted-access Medical Expenditure Panel Survey (MEPS) with state identifiers, but the MEPS is only approximately 15% of the size of the SIPP, with 160 individuals in Massachusetts, so sample size is not large enough for us to obtain reliable results.

resulting in person-month-level data. Interview months differ across individuals in the sample. Previous research has shown evidence of “seam bias” in the SIPP, whereby individuals tend to give the same responses during one interview for all four months associated with the interview period, but they do change responses from one interview to the next (see Chetty (2008)). To address seam bias, we restrict our data to the interview month in our regression specifications. We use weights in all summary statistics and regressions to account for SIPP’s sampling and response unit design.<sup>13</sup>

We use the full 2004 SIPP panel, which covers October 2003 to December 2007. The main limitation of this SIPP panel is that it does not extend for a long time after reform was fully implemented. Although we observe a relatively short period of responses after all of the aspects of the reform were in effect on July 1, 2007, we also observe a full year of responses during the implementation of the reform. Following our previous work, we refer to the period from July 2006 through June 2007 as the *During* period and the period from July 2007 forward as the *After* period. By doing so, we attain different estimates during the period in which it was initially rolled out and after the period in which it was fully implemented. Furthermore, open-enrollment periods for ESHI are generally in November, with new coverage starting in January. Thus, to satisfy the individual mandate in July 2007 by taking up ESHI, many individuals would have to start coverage in January 2007, well before our data ends at the end of December 2007.

Another limitation of the 2004 SIPP panel is that the sample size decreases over time, due primarily to interview reductions. Our group of interest is the population under age 65, without military health insurance or Medicare. In 2004, there are 91,771 unique individuals (716,606 observations) in this sample across states, of which 2,690 unique individuals (20,457 observations) are in Massachusetts. In 2007, there are 35,733 unique individuals (320,775 observations) in the sample, of which 847 unique individuals (7,513 observations) are in Massachusetts. However, we still have a large enough sample to find statistically significant results in our main specifications.

The SIPP allows us to construct our main dependent variables: hourly wages  $w$  and hours worked per week  $L$ . The SIPP allows respondents to report wages and hours for up to two jobs. Our main estimates rely on income and hours worked only in the primary job. Because the SIPP data only include monthly income, not monthly wages, we must divide income by a measure of hours worked to obtain monthly wages. However, because our model relies on separate movements in  $w$  and  $L$ , it would be problematic for both measures to reflect contemporaneous movements in

---

<sup>13</sup>Our main analysis uses data from the core content of the SIPP. We construct our data by appending the 12 individual-wave files from the 2004 panel and merging longitudinal weights onto the full file by individual person identifiers. Longitudinal panel weights account for people who were in the sample in wave 1 of the panel and for whom data were obtained (either reported or imputed) for every month of the panel. There are four panel weights associated with the 2004 SIPP panel; the first covers people present in waves 1-4, the second covers people in waves 1-7, the third covers people in waves 1-10, and the fourth covers people who have data for the whole sample (waves 1-12). The panel weighting scheme does not assign weights to people who enter the sample universe after wave 1 (panel weight=0 if the individual was not in the sample in wave 1, if they have missing data for one or more month(s), or both). In choosing the appropriate weights, there is a tradeoff between length of individual data and reductions in sample size associated with attrition. Our preferred specification does not use panel weights and instead uses individual weights, therefore maximizing the number of respondents. In results not reported, we re-estimate our main regressions using each panel weight. Reassuringly, the main coefficients of interest are relatively robust to these weight changes. Using weights 3 or 4 does lead to substantial loss of precision as the sample size falls when moving from longitudinal weight 1 to 4.

*L.* To get around this issue, which is related to the common division bias problem from the labor economics literature, we divide income by the average hours reported in the first four interviews (representing a 16-month period). Our regression estimates are robust to the alternative wage measures, likely because hours move infrequently.

## 6.2 Summary Statistics

Before proceeding to our regression results, we assess the empirical validity of comparing Massachusetts to other states by comparing labor market, health insurance, and demographic variables. We also compare labor market trends in Massachusetts and other states based on ESHI status, as required by our model. Our identification will be most convincing if labor market trends are similar in Massachusetts and other states before reform.

Our identification can also be convincing if we observe similar aggregate labor market trends in Massachusetts and other states *after* the reform. From prior research, we know that, while the reform resulted in a significant decline in the percentage of people without health insurance, only approximately 6 percentage points of the population gained health insurance coverage. Of those who gained coverage, roughly half gained ESHI and the other half gained subsidized coverage (Kolstad and Kowalski (2010)). While we do expect potentially large labor market impacts for individuals who switched ESHI status as a result of reform, even very large impacts for these individuals should only result in small changes in the aggregate labor market. To the extent that we do see changes in the aggregate labor market, they could reflect impacts of reform, or they could reflect factors unrelated to reform that differentially affected Massachusetts relative to other states after reform. If we are worried about the latter, we can incorporate variation by firm size.

We report summary statistics in Table 4. We compare the full population, the Massachusetts population, and the non-Massachusetts population before reform (October 2003 to June 2006) and after reform (July 2007 to December 2007). We exclude the during reform period for simplicity. In this table, we include all months, not just interview months. The sample size in each row is different, depending on data availability. In this table and throughout the paper, we deflate wages by the 2006 CPI.

The first row of the table shows our primary measure of  $w$ : weekly earnings divided by baseline hours per week, including zero wages for individuals without a paid job. Wages are higher in Massachusetts than they are in other states before and after reform. Netting out the change in wages in other states from before to after reform, as shown in the last column, hourly wages increased by \$1.83 in Massachusetts after reform on a base of \$17.86 before reform. This increase is significant at the 99% level. Excluding individuals without a paid job in the second and third rows of the table, we see that wages increased by \$0.30, 1.7% among the employed, which is less than the wage increase that we see in the full sample, suggesting that part of the wage increase we observe is driven by an increase in the number of people with paid jobs. Indeed, the probability of reporting a paid job increased by 4.5 percentage points in Massachusetts after reform on a base of 80% before reform.

Table 4: Summary Statistics

	Full Population		MA		Non-MA		MA-Non-MA
	Before	After	Before	After	Before	After	After-Before
w: Weekly earnings / baseline hours per week	13.87	14.60	17.86	20.39	13.78	14.47	1.829***

w and L measures include individuals without a paid job with w=0 or L=0, respectively, unless noted otherwise.

Results in the fourth row suggest that hours increased by 1.8 hours per week in our preferred measure of  $L$ , which includes zero hours for individuals without a paid job. However, the increase in hours appears to entirely reflect an increase in employment. Among individuals with a paid job, hours decreased by 0.20 hours per week on a base of 37.8 hours per week before reform, or by 0.2% in the logarithmic specification. The next row shows that by focusing on the first job only in our primary measure of  $L$ , we account for approximately 95% of hours in all jobs.

Taken together, these results suggest that Massachusetts experienced increased wages and increased hours overall, with some of the increase in wages and all of the increase in hours operating through increased employment. The increases in wages and hours that we observe are not consistent with the theoretical impact of an increase in ESHI for those who gained coverage, suggesting that mandate-based reform in Massachusetts had little if any impact on the aggregate labor market. To understand what is driving the labor market changes that we observe, we first examine the differences-in-differences impact on health insurance coverage in our sample, and then we examine wage trends at high frequency in Massachusetts and other states by ESHI status.

In the middle rows of Table 4, we compare insurance coverage in Massachusetts and other states. Massachusetts has higher insurance coverage rates than other states; approximately 92% of individuals under the age of 65 without Medicare or military health insurance in Massachusetts had some type of health insurance before reform, increasing to 96% after reform. Outside of Massachusetts, health insurance coverage increased slightly from 85% to 86% over the same period. The simple differences-in-differences estimate for the increase in coverage in Massachusetts due to

the reform is 3.5 percentage points; slightly lower but consistent with existing estimates (Long (2008); Kolstad and Kowalski (2010); Yelowitz and Cannon (2010)). ESHI coverage rose from 78% to 79% in Massachusetts from pre-reform to post-reform; coverage was steady at approximately 70% in non-Massachusetts states.

The final rows of Table 4 compare demographic characteristics in Massachusetts and other states. We see that roughly the same percent of individuals with paid jobs work for large firms in Massachusetts and other states (88% before reform). Massachusetts residents have higher incomes, so smaller numbers of individuals in Massachusetts qualify for Medicaid and CommCare under the Massachusetts reform thresholds. Other demographic characteristics reported look similar. We will control for time-invariant demographic characteristics in our regressions using individual fixed effects.

### 6.3 Wage Trends by ESHI Status

Figures 2 and 3 show wage trends over time by ESHI status in Massachusetts and other states, using the level of wages and the logarithm of wages, respectively. In these figures, as in the previous table, we use data from all months, not just interview months.

These figures give us several insights into the empirical relationship between ESHI and labor market outcomes in Massachusetts and other states. First, inside and outside of Massachusetts, wages are higher for jobs with ESHI than for jobs without ESHI, consistent with the literature that finds no compensating differential for ESHI. Second, within jobs with the same ESHI status, wages were higher in Massachusetts than other states before reform, but they were trending similarly. Massachusetts trends are noisier because they are based on a smaller sample of respondents. The trends are noisiest at the end of the sample period, when the sample size decreases. Third, after the reform, there is a barely visible increase in the slope of the Massachusetts trend lines relative to the trend lines outside of Massachusetts, which was reflected in our previous difference-in-differences estimates. Because of this issue, we incorporate variation by firm size in our preferred specifications.

Before incorporating variation by firm size, we explore the impact of incorporating longitudinal variation on wage trends by ESHI status for Massachusetts compared with other states. Because incorporating longitudinal variation places greater demands on the data, making the trend lines noisier, we combine each monthly response into mutually exclusive two-month periods. We run a regression analogous to our baseline (no bracketed terms) specification given by equation (3), where the only change is that we replace every instance of *After* with a vector of all two-month periods in our data, omitting only the last two-month period before reform (May-June 2006).

In Figure 4, we plot the vector of coefficients corresponding to  $\beta_{12}$  with the points connected by the dashed line labeled *ESHI*. This line gives the wage premium for jobs with ESHI relative to jobs without ESHI outside of Massachusetts. We define the wage premium as the empirical difference in wages between jobs with ESHI and jobs without ESHI; this might not be equal to the compensating differential in our model in the absence of adequate identification. We also plot the vector of coefficients corresponding to  $\beta_1$  with the points connected by the solid line labeled

Figure 2: Wage Trends, MA vs. Non-MA

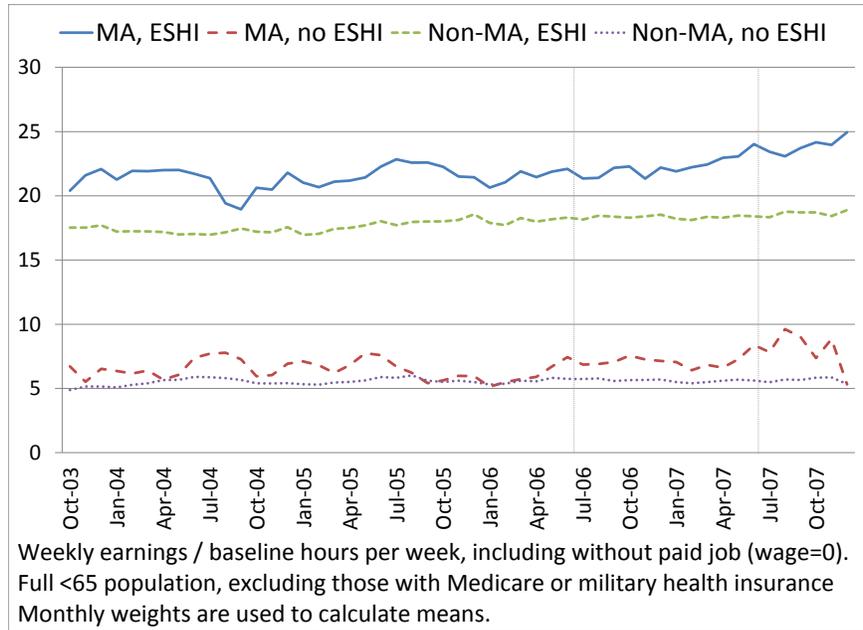

Figure 3: Log Wage Trends, MA vs. Non-MA

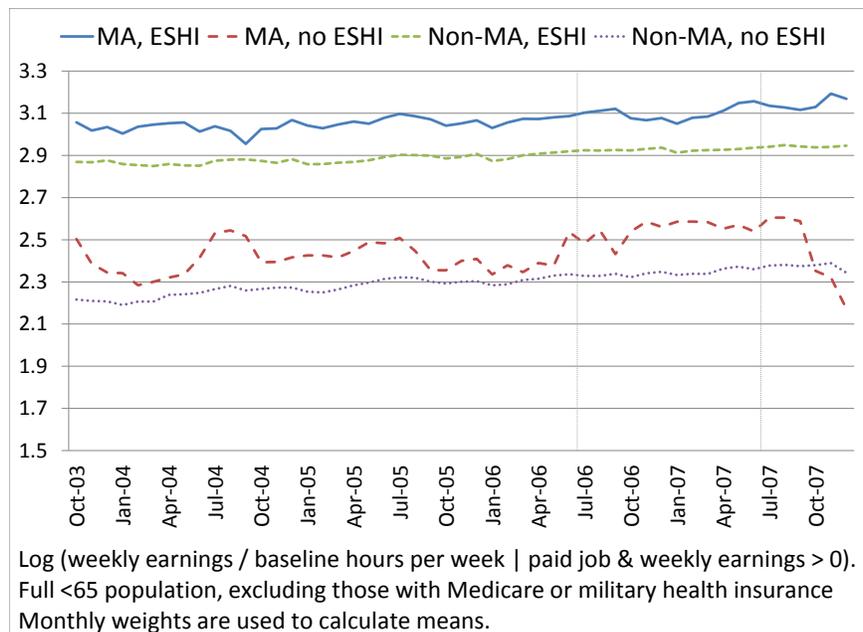

Figure 4: Longitudinal Wage Premium for Jobs with ESHI Relative to Jobs Without ESHI, MA vs. Non-MA

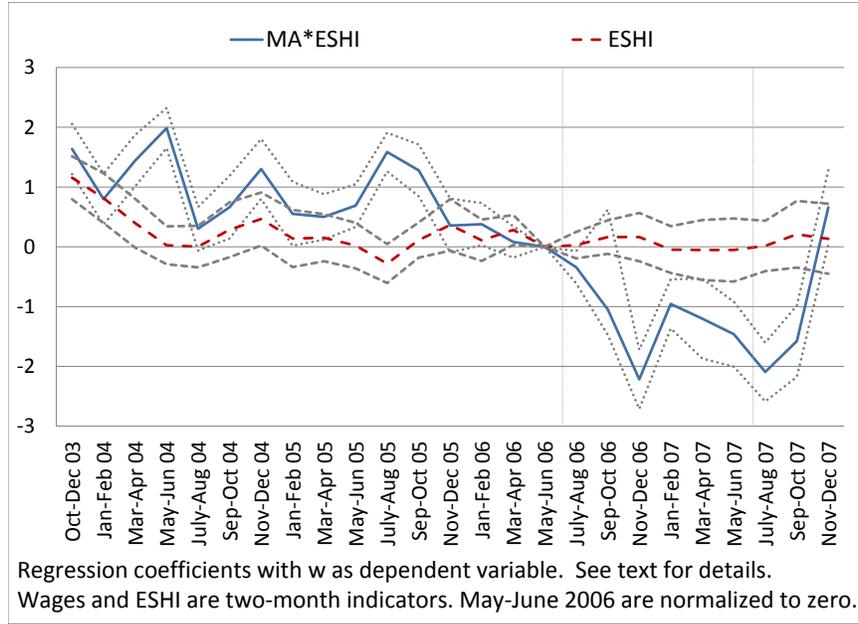

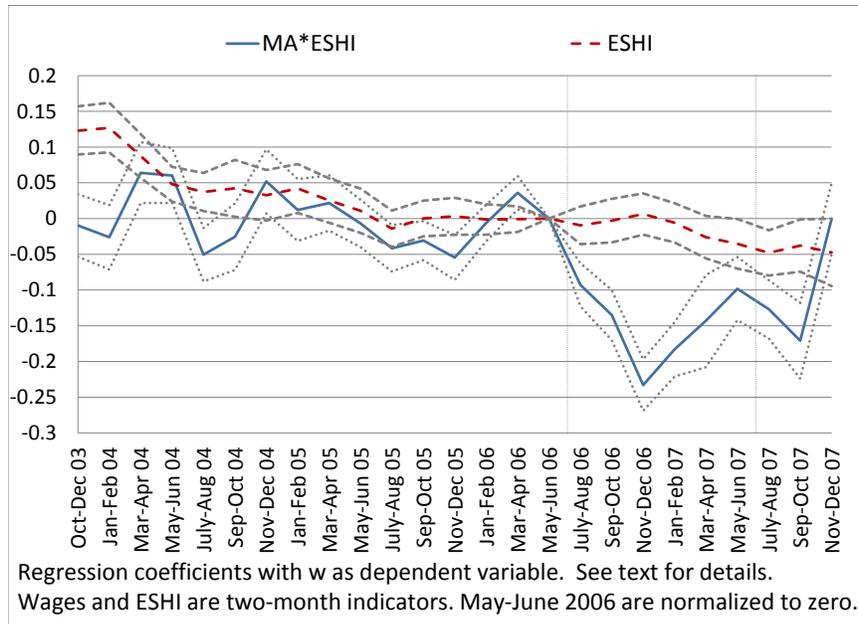

Figure 5: Longitudinal Log Wage Premium for Jobs with ESHI Relative to Jobs Without ESHI, MA vs. Non-MA

$MA * ESHI$ . This line gives the differential wage premium for ESHI jobs relative to jobs without ESHI in Massachusetts, relative to other states. We also show 95% confidence intervals for both lines, block clustered by state. In Figure 5, we plot the corresponding coefficients from a regression with the logarithm of wages as the dependent variable, estimated only on individuals with a paid job. Because individual fixed effects are included in the regressions, the coefficients corresponding to  $\beta_{12}$  are identified by people outside of Massachusetts who change ESHI status in the given period relative to the omitted period. The coefficients corresponding to  $\beta_1$  are identified by people within Massachusetts who change ESHI status in the given period relative to the omitted period or by people who move between Massachusetts and other states in the given period relative to the omitted period.

In the omitted period, the wage premium for jobs with ESHI relative to jobs without ESHI is normalized to zero. Outside of Massachusetts, we see that the wage premium for ESHI jobs increases over time in Figure 4. However, when we examine the log wage premium in Figure 5, we see a downward trend, suggesting that wages increase faster in jobs without ESHI, reflecting the secular increase in the cost of health insurance relative to inflation over this time period.

Within Massachusetts, as shown in Figure 4, the premium for ESHI jobs relative to jobs without ESHI is higher before the reform relative to other states. However, it trends similarly for individuals with paid jobs before reform, as shown in Figure 4. The similar trends in Massachusetts and other states before reform lend support to our identification strategy.

Following the passage of reform in Massachusetts, we see a striking shift in the relationship between ESHI and wages for individuals who switch ESHI status. There is a substantial drop in the wage premium for ESHI jobs relative to jobs without ESHI during and after the reform in Massachusetts relative to the period before the reform and relative to other states. This is true for all of the two-month periods after May-June of 2006 except for for the last two-month period, which shows a puzzling increase in both figures. The increase seems to be due to sizeable attrition from the sample in the last two months and not to a real increase in the wage premium. If we examine the underlying data more closely, we see that there are approximately 4,000 observations (with multiple observations for approximately 2,000 unique individuals) in Massachusetts in each two-month period before reform, and approximately 1,500 observations (about 725 unique individuals) in Massachusetts in each two-month period after reform, with the exception of the last two-month period, Nov to Dec 2007, in which there are only 511 observations (350 unique individuals). Our baseline regression, which pools all data within the before, during, and after periods separately, places little weight on the visible uptick in the very last two-month period because of the small sample size from which it is drawn.

Although the regression results formalize the magnitude of the decline in the wage premium after reform, we can learn something about the magnitude by examining Figures 4 and 5, keeping in mind that the last point gets the smallest weight. We should also keep in mind that we expect wages for jobs with and without ESHI to fall in Massachusetts after reform, and by analyzing coefficients that correspond to  $\beta_1$  only, we are assuming that there is no employer penalty. The true compensating differential that takes the employer penalty into account will be larger than

the effects we observe. In Figure 4, the magnitude of the decline in the wage premium for ESHI jobs in Massachusetts over the entire period during and after reform appears to be approximately \$2/hour, which corresponds to a roughly 10% decline in Figure 5. These figures provide the first evidence that the Massachusetts reform affected jobs with ESHI, as we predict in our model. They also signal that this can be an exogenous sources of variation that will be useful in identifying a compensating differential for ESHI.

## 7 Results and Discussion

We report results from the baseline wage and hours equations in Table 5, and we begin our analysis by examining the coefficients directly. Recall that  $\beta_1$  gives the compensating differential and  $\gamma_1$  gives the hours differential if we assume that there is no employer penalty and, therefore, individuals without ESHI in Massachusetts after reform provide an additional control group for individuals with ESHI in Massachusetts after reform. The estimated  $\beta_1$  tells us that hourly wages are \$2.61 lower for individuals with ESHI relative to individuals without ESHI, after the reform relative to before the reform, in Massachusetts relative to other states. This coefficient is statistically significant at the 99% level. Annualizing the decrease in hourly wages for a full-time worker, this coefficient implies that the compensating differential for ESHI is  $-5,426.72 (= -2.609 * 40 * 52)$  dollars per year. This compensating differential is of the expected sign, standing in contrast to much of the literature.

To get a sense of what we expect the magnitude of the compensating differential for ESHI to be, recall that the absolute value of the compensating differential will be equal to the cost of ESHI to employers  $b$  if the employer penalty  $\rho$  is equal to zero and the penalty-and-subsidy-inclusive valuation  $\alpha + \lambda - \mu_x$  is full. Before estimating  $b$  using our model, we calculate a comparison estimate from the Kaiser Family Foundation 2007 Survey of Employer Health Benefits (Kaiser Family Foundation (2007b)). The average 2007 premium was \$4,355 for an individual plan and \$11,770 for a family plan (all amounts converted to 2006 dollars). The average employer contribution was 85% for an individual and 73% for a family plan. We weight our estimate of the annualized  $b$  to reflect the likely share of individual vs. family plans in the SIPP population. Using the share of the SIPP population with ESHI after reform who report having at least one child to calculate the share of family plans, the average annualized  $b$  was \$6,105. Alternatively, using the same family definition and the share of the same SIPP population who switched from not having ESHI in 2006 to having it after reform, the average annualized  $b$  was \$5,576. In this context, the magnitude of the compensating differential we estimate based on  $\beta_1$  seems reasonable, especially considering that the assumption that the employer penalty is zero should bias our estimate toward zero, suggesting that our preferred estimate will be larger and even more in line with actual costs of ESHI to employers.

If we do not assume that the employer penalty is zero, our preferred estimate of the compensating differential from the baseline model is  $\beta_1 + \beta_8 + \beta_{11} = -2.609 + 2.054 + 3.215 = 2.660$ , which is of the wrong theoretical sign. Recall from Section 5.1 that if the employer penalty is small and there are no labor market changes in Massachusetts relative to other states after reform, we expect  $\beta_{11}$  to be small relative to  $\beta_1$  and negative. Similarly, if our individual fixed effects allow us to

identify the compensating differential convincingly without using variation in ESHI induced by reform, we expect  $\beta_8$  to be small and negative relative to  $\beta_1$ . However, both are positive and of the same order of magnitude as  $\beta_1$ . Our estimated  $\beta_{11}$  suggests that something other than reform differentially affected the labor market in Massachusetts relative to other states (confirming our discussion of summary statistics), so we prefer the specification that incorporates variation by firm size. Our estimated  $\beta_8$  suggests that we need variation in ESHI induced by reform to estimate the compensating differential for ESHI (our estimated compensating differential is \$3.22 in Massachusetts before reform, netting out differences with other states), so we focus on our preferred estimate that compares equilibrium  $A$  to equilibrium  $F$  within our preferred specification.

In the second column of Table 5, our estimate of the hours differential using  $\gamma_1$  tells us that weekly hours are -1.183 lower for jobs with ESHI relative to jobs without ESHI in Massachusetts relative to other states, after reform relative to before reform. Recall that if the penalty-and-subsidy-inclusive valuation of the benefit is full, the hours differential will be zero. This estimate is statistically different from zero at the 99% level, suggesting that the penalty-and-subsidy-inclusive valuation will be less than full, and we need to turn to our model to calculate it. Analysis of the  $\gamma_8$  and  $\gamma_{11}$  coefficients parallels analysis of the  $\beta_8$  and  $\beta_{11}$  coefficients, suggesting that the specification with firm size interactions will be our preferred specification.

## 7.1 Estimates of the Compensating Differential for ESHI

To obtain our preferred estimates of the compensating differential and hours differential for ESHI, we estimate our preferred specification with firm interaction terms, and we report the results in Table 6. To isolate small firms that are not subject to the employer mandate, we categorize individuals without paid jobs as working for a large firm. This specification is more complicated than our baseline specification, so it is less intuitive to examine the coefficients directly. However, we can synthesize all of the relevant information in the coefficients by plotting the empirical equilibria that map to the theoretical equilibria presented in Figure 1. Figure 6 plots the empirical equilibria. All equilibria are relative to equilibrium  $A$  (no ESHI before reform) at the origin.

The most important relationship to notice in Figure 6 is that equilibrium  $F$  (ESH I after reform) is to the lower left of equilibrium  $A$  (no ESHI before reform), as predicted by our theory. The relationship between  $A$  and  $F$  is the best-identified relationship in the figure. Our preferred estimate of the compensating differential for ESHI from Table 1 is the negative of the vertical distance between equilibrium  $A$  and equilibrium  $F$ . As depicted in Figure 6, the third column of Table 6 shows that  $w_F - w_A$  is equal to -\$2.91 per hour. Annualizing the point estimate for a full-time worker, the implied compensating differential is -\$6,058 per year, which is only slightly smaller in magnitude than the average cost of ESHI to employers. This suggests that the magnitude of our estimate is in a plausible range and that the penalty-and-subsidy-inclusive valuation is less than full. We obtain the annualized 95% confidence interval on the compensating differential of -\$8,611 to -\$4,098 per year by block-bootstrapping by state.<sup>14</sup>

<sup>14</sup>To obtain all confidence intervals, we perform a simple nonparametric block bootstrap. We first draw a sample

Figure 6: Empirical Estimates of Wage and Hours Equilibria

We obtain our preferred estimate of the hours differential for ESHI by taking the negative of the horizontal distance between equilibrium  $A$  and equilibrium  $F$ . As depicted in Figure 6, the third column of Table 6 shows that  $L_F - L_A$  is equal to -1.47 hours per week. This estimate is statistically different from zero at the 99% level, also suggesting that the penalty-and-subsidy-inclusive valuation is less than full.

Another key relationship to notice is that equilibrium  $B$  (no ESHI after reform) is also to the lower left of equilibrium  $A$  (no ESHI before reform), as predicted by our theory. However, the theory also predicts that equilibrium  $B$  should have higher wages than equilibrium  $F$  when the penalty is small (the hours comparison is ambiguous because it also depends on the magnitude of the penalty-and-subsidy-inclusive valuation), but empirically we see that equilibrium  $B$  has slightly lower wages than equilibrium  $F$ , leading to a wrong-signed compensating differential  $w_F - w_B$ . Because the relationship between equilibrium  $B$  and equilibrium  $A$  is not identified by changes in ESHI status due to reform, we have reason to doubt our identification of  $B$ .

Finally, theory tells us that equilibrium  $D$  (ESHI after reform) should be to the lower left of equilibrium  $A$  (no ESHI before reform), but the empirical equilibrium  $D$  is to the upper left of

---

of 51 states with replacement — the data include all 50 US states and the District of Columbia — drawing all observations within a state as a block. We then estimate the wage and hours equations on the same sample, thus taking into account that the same individuals are used to estimate the wage and hours equations. To include as much data as possible, we drop observations with missing values of either outcome after selecting the replication sample, thereby assuming that individuals with missing data have the same behavior as those without missing data. We repeat the sampling process for 350 replications. For each quantity in column 3, we report the 0.025 quantile and the 0.975 quantile as our 95% confidence interval. We report significance when this confidence interval or the analogous 90% or 99% confidence interval does not include zero.

equilibrium  $A$ . As shown in the third column of Table 6, the compensating and hours differentials, based on equilibrium  $D$  are wrong-signed. The observed relationship between equilibrium  $D$  and equilibrium  $A$  is yet another manifestation of the well-known issue in the literature that it is difficult to find a correctly-signed compensating differential without exogenous variation in the benefit. Because we cannot convincingly identify  $D$ , we are not able to separately identify the components of the penalty-and-subsidy-inclusive valuation of health insurance,  $\alpha$  and  $\lambda - \mu$ . As shown in the third column of Table 6, our separate estimates of these parameters are nonsensical. Although these parameters would be interesting to analyze, we do not need to separately identify them to identify the aggregate welfare impact of mandate-based health reform.

## 7.2 Estimating the Welfare Impact of Health Reform

We next translate our preferred estimates of the compensating and hours differentials into the welfare impact of health reform. Up to this point, our results have come directly from the regression coefficients, and we have not made any calibrations. In theory, all of the sufficient statistics for the deadweight loss for health reform given by equation (1) are identified. However, as we discuss above, we have reason to believe that the identification for equilibrium  $B$  and equilibrium  $D$  is not convincing, and plotting the empirical equilibria gives us further cause to doubt their identification. For this reason, we rely only on the difference between labor market equilibria that is best-identified (equilibrium  $F$  relative to equilibrium  $A$ ), and calibrate other sufficient statistics as necessary.

We first translate our estimated compensating and hours differentials into our key sufficient statistics — the cost of ESHI to employers  $b$  and the penalty-and-subsidy-inclusive valuation  $\alpha + \lambda - \mu_x$ . We can see from the expressions in Table 2 and the geometry of Figure 6 that an estimate of the slope of the demand curve is sufficient to translate the compensating and hours differentials into  $b$ , and an estimate of the slope of the supply curve is sufficient to translate the compensating and hours differentials into  $\alpha + \lambda - \mu_x$ . Using elasticity estimates from the literature, discussed in Section 4.3, and average hours and wages for the full SIPP sample before reform, we set the slope of the supply curve equal to 0.19, and we set the slope of the demand curve equal to -0.38.<sup>15</sup> As shown in Figure 6 and in the third column of Table 6, we obtain a value of 3.47 for  $b$ , which translates into \$7,220 annually for a full-time worker. We obtain a value of 0.759 for the penalty-and-subsidy-inclusive valuation, which suggests that workers value health expenditures made by their employers at about 76 cents per dollar.

Next, we translate the penalty-and-subsidy-inclusive valuation of health insurance into the deadweight loss of mandate-based health reform for individuals who have ESHI after reform, depicted as triangle  $F'AF''$  in the theoretical and empirical figures. The area of the triangle is equal to 0.616, which translates into an annual deadweight loss of \$32 (=0.616\*52) for a full-time worker. This deadweight loss is only 6% of the size of the deadweight loss triangle associated with tax-based reform  $TAT'$ , assuming that the tax  $\tau$  is equal to the cost of the benefit to employers  $b$ .

<sup>15</sup>We report the calibrated values of  $s$  and  $d$  in Table 6 because we use them to calibrate the subsequent statistics. The estimated value for  $s$  is 1.95 with a 95% confidence interval of [1.12,6.13]\*\*\*, and the estimated value for  $d$  is 2.15 with a 95% confidence interval of [1.65,3.25]\*\*\*.

Finally, we calculate the deadweight loss of mandate-based health reform for individuals who do not have ESHI after reform, which requires an estimate of  $\rho$ . Rather than estimating  $\rho$  using equilibrium  $B$ , we calibrate it such that the dollar value of the employer penalty  $\rho b$  is equal to the statutory penalty of \$295/year. We plot the analog of equilibrium  $B$  that corresponds to the calibrated  $\rho$  as the point  $B_\rho$ . The associated welfare triangle is given by  $B_\rho AB'$ . The empirical area of this triangle is 0.0176, which translates into an annual deadweight loss of \$0.92 (=0.0176\*52) for a full-time worker.

To obtain the deadweight loss of mandate-based health reform,  $DWL_m$ , we weight the two triangles by ESHI status in Massachusetts after reform, setting  $ESHI_{After}$  equal to 0.79, according to our table of summary statistics. Putting everything together using equation (4), we find that the deadweight loss of mandate-based health reform is equal to \$25 per year for a full-time worker. Relative to tax-based health reform, mandate-based health reform is substantially more efficient: using equation (5), we calculate  $DWL_m/DWL_\tau = .046$ ; the distortions that mandate-based health reform induces are less than 5% of the distortions induced by tax-based health reform.<sup>16</sup>

### 7.3 Robustness to Calibrated Values

Thus far, we have discussed point estimates for the welfare impact of health reform, but we are also interested in their robustness. The confidence interval reported in Table 6 suggests that we are 95% certain that the deadweight loss of mandate-based health reform is between 1.2% and 13.5% of the deadweight loss of tax-based health reform. However, although the reported confidence intervals should be of the correct size for the compensating and hours differentials, the other confidence intervals should be too small because they reflect calibrated values, which were themselves estimated elsewhere. Therefore, it is instructive to consider robustness to alternative calibrated values.

First consider alternative values of  $\rho$  and  $ESHI_{After}$ . These values have little impact on our overall conclusion that mandate-based health reform is substantially more efficient than tax-based health reform in Massachusetts. Our preferred calibrated  $\rho$  is 0.041, reflecting that the statutory employer penalty of \$295 is approximately 4.1% of the estimated cost of ESHI  $\hat{b}$ . If we increase  $\rho$  such that the penalty is instead 25% of the estimated cost of ESHI, the deadweight loss for individuals without ESHI after reform is equal to the deadweight loss for individuals with ESHI after reform, which is approximately 6% of the deadweight loss of mandate-based health reform. In this case,  $ESHI_{After}$  has no impact because the size of both triangles is the same.

As discussed in Section 2, employer penalties under the ACA are substantially larger than those under the Massachusetts reform, up to a maximum of \$3,000 per employee annually, approximately 42% of the estimated cost of ESHI. However, the deadweight loss for individuals without ESHI

<sup>16</sup>We find that the deadweight loss of tax-based health reform is \$550 per year for a full-time worker. A tax of size  $\tau = b = \$3.47$  per hour, would raise \$4,140 per person per year ( $\$3.47$  per hour \* (29.03 hours per week in Massachusetts before reform - 6.09 hours per week after reform) \* 52 weeks per year), which would not be large enough to finance the estimated average annual cost of ESHI per worker of \$7,220. Therefore, we are conservative in setting  $\tau = b$ . Under the tax, the ratio of the deadweight loss to revenue raised is 0.13, which is on the lower end of the range but consistent with prominent estimates from the literature such as Ballard et al. (1985) and Feldstein (1999).

after mandate-based reform is only 17% of the deadweight loss of tax-based reform; this is because triangle  $B_{\rho}AB'$  grows with the square of the penalty, but triangle  $TAT'$  grows with the square of the cost of ESHI. Taking into account the triangle  $F'AF''$ , the overall welfare cost of mandate-based reform is only 8.2% of the welfare cost of tax-based reform.

Next, consider alternative values for the loading cost of ESHI relative to the loading cost of government-provided health insurance,  $b/\tau$ , keeping all other values the same as in our preferred specification. Suppose that ESHI costs 10% more to provide than government-provided health insurance because the government has economies of scale relative to employers, so  $b/\tau=1.1$ . The deadweight loss of tax-based health reform decreases to \$454 annually, but the deadweight loss of mandate-based health reform is still only 5.6% as large. Even if  $b/\tau=1.50$  such that ESHI costs 50% more to provide than government-provided health insurance, the deadweight loss of mandate-based health reform is still only 10.4% of the deadweight loss of tax-based health reform.

The last calibrated values to consider are the slope of the supply curve  $s$  and the slope of the demand curve  $d$ . To examine the effect of  $s$  and  $d$  on the ratio of the deadweight loss of mandate-based health reform to the deadweight loss of tax-based health reform, we see from equation (2) that the ratio of the deadweight loss of mandate-based health reform to the deadweight loss of tax-based health reform grows with the square of the percentage of the cost of ESHI that workers do not value:  $(1 - \alpha + \widehat{\lambda - \mu_x})$ . Using the expressions in Table 2, we can express this percentage in terms of the compensating and hours differentials, the slope of the demand curve, and the slope of the supply curve. We find that the relative deadweight loss of mandate-based reform increases as the slope of the labor supply curve increases (becomes more inelastic) and increases as the slope of the labor demand curve decreases (becomes more elastic). Holding demand constant, if we increase the calibrated labor supply elasticity from 0.1 to 0.2 (from  $s = 0.1 * 27.68/14.60 = 0.19$  to  $s = 0.38$ ), the relative deadweight loss increases to 8.2%. If we increase it further to 0.5 ( $s = 0.95$ ), the relative deadweight loss increases to 25%. Alternatively, holding supply constant, if we decrease the calibrated labor demand elasticity from -0.2 to -0.4 (from  $d = -0.2 * 27.68/14.60 = -0.38$  to  $d = -0.76$ ), the relative deadweight loss increases to 9.5%. If we decrease it further to -1.2 ( $d = -2.28$ ), the relative deadweight loss increases to 26.5%. Thus, the finding that mandate-based health reform is efficient relative to tax-based health reform is robust to changes in calibrated labor supply and demand.

The slopes of the supply and demand curves do, however, fix the incidence of the deadweight loss of health reform on employees versus their employers. As we can see from Figure 6, as supply becomes less elastic, a larger fraction of each deadweight loss triangle is below the  $L$  axis, demonstrating that employees bear more of the burden of reform. Conversely, as demand becomes less elastic, a larger fraction of each deadweight loss triangle is above the  $L$  axis, demonstrating that employers bear more of the burden of reform.

## 7.4 Robustness to Different Estimation Samples

Thus far, our model has taken individual ESHI takeup decisions as exogenous. Therefore, individuals who switched into ESHI because of reform are representative of all individuals, and we have estimated the penalty-and-subsidy-inclusive valuation for the population. However, we can extend our model to make ESHI status endogenous by allowing underlying valuations, and thus penalty-and-subsidy-inclusive valuations, to vary across individuals. In this extended model, after allowing for some optimization error, individuals with a penalty-and-subsidy-inclusive valuation above a certain threshold purchase health insurance in each period. Individuals with the highest intrinsic valuation of health insurance  $\alpha$  already have health insurance before reform. The reform will increase penalty-and-subsidy-inclusive valuations for some individuals, leading them to take up ESHI. Interpreted in light of the extended model, our estimates then reflect the average penalty-and-subsidy-inclusive valuation among individuals who take up ESHI. Therefore, our estimated valuation of 0.76 from our preferred specification suggests that individuals who take up ESHI because of reform value it at 76 cents on the dollar on average (even after taking the tax-preference for ESHI into account), so they would not have taken it up in the absence of reform.

Under the extended model with endogenous takeup of ESHI, we can test whether the penalty-and-subsidy-inclusive valuation (and thus the incidence of reform among employees) varies across different populations by estimating our model on subsets of our estimation sample. Under our original model, the same specifications test the robustness of our estimates to alternative samples and control groups. We examine our baseline and preferred specifications on three subsets of the full population: individuals in New England, those earning more than 300% of the FPL, and those who are married.

In the first column of Tables 7 and 8, we restrict our estimation sample to include only individuals in New England, on the grounds that Massachusetts might be more similar to other New England states than it is to the rest of the country. Table 7 reports results from the baseline specification on the New England sample. The estimates of  $\beta_1$  and  $\gamma_1$  (the compensating and hours differentials assuming that the employer penalty is zero, respectively), are slightly larger in magnitude than the corresponding estimates from the baseline specification. However, the 95% confidence intervals on both coefficients include the respective coefficients from the main sample. Furthermore, the compensating and hours differentials from the preferred specification are very similar to those from the main sample. In the sample that includes only New England, the annualized estimate of the cost of ESHI  $b$  is \$9,703, slightly larger than our main estimate (\$6,058), but the penalty-and-subsidy-inclusive valuation of 0.69 is very similar to our main estimate (0.76). Furthermore, the ratio of the deadweight loss of mandate-based health reform to the ratio of the deadweight loss of tax-based health reform is 7.7% — which is similar to our main estimate of 4.6%.

In the second column of Table 7, we restrict our estimation sample to include only individuals above 300% of the federal poverty level before reform. We classify individuals into income groups using the first period of available data to avoid regressing wages on contemporaneous measures of income. Individuals above 300% of FPL before reform are not eligible for any subsidies, which

means that their penalty-and-subsidy-inclusive valuation should be higher. As we show in the second column of Table 8, the point estimate for the penalty-and-subsidy-inclusive valuation in this sample is indeed much higher than it is in the main specification — it is almost full. Because the penalty-and-subsidy-inclusive valuation in this sample is so large, mandate-based health reform causes minimal distortion to the labor market. The ratio of the deadweight loss of mandate-based health reform to that of tax-based health reform is 0.3%.

In the third columns of Tables 7 and 8, we restrict our estimation sample to include only married individuals. Married individuals could value ESHI less than other individuals if they have health insurance options available through their spouses; alternatively, they could also value it more if their spouse relies on them for insurance. Empirically, we see in Table 8 that the valuation of ESHI for married individuals is approximately 0.80, with a 95% confidence interval of 0.74 to 0.88, slightly larger than the valuation of ESHI for the full sample.

 Excluding >=age 65, Medicare beneficiaries, military health insurance beneficiaries. Only includes interview months.  
 All specifications include individual, state, and state\*large firm fixed effects. Monthly weights used.  
 Large firm defined as >25 employees.  
 New England states include MA, CT, NH, VT, ME, RI.  
 300%FPL+ sample includes those who DO NOT fall into the <150%FPL or 150-300%FPL categories

## 7.5 Robustness to Intensive Margin Only

Thus far, we have not distinguished the extensive margin decision of whether to work at all from the intensive margin decision to work a different number of hours in our measure of  $L$ . Instead, we have attempted to capture the broadest possible impact of reform by allowing for responses on the intensive and extensive margins. However, previous research, including Cutler and Madrian (1998), shows that ESHI could have different impacts on employment than it does on hours because ESHI has a fixed cost, regardless of hours worked.

We now investigate whether we observe responses on the intensive margin and whether the distinction between the intensive and extensive margins affects our findings. We first restrict our sample to include only individuals with a paid job and positive wages in a given period. We then further restrict our sample to include only individuals with a paid job and positive wages over the entire period, and then further to include only individuals with no job switch over the entire period. We adjust the calibrated values of  $s$  and  $d$  to reflect the higher average wages and hours. Because these three samples only include people with positive wages and hours, we can also estimate logarithmic specifications without losing any information. In the logarithmic specifications, our theoretical graph stays the same, the axes change from  $w$  to  $\log(w)$  and from  $L$  to  $\log(L)$ . With the change in axes, the compensating differential and the cost of the benefit are percentages of wages instead of dollar amounts, and the hours differential is a percentage of hours. However, the units of the penalty-and-subsidy-inclusive valuation and the deadweight loss ratio do not change.

Table 9 presents results from the baseline specification on the three samples of workers, using levels and logarithms of the dependent variables. In all samples, our estimates of  $\beta_1$  give evidence of a compensating differential, assuming no employer penalty. The logarithmic specifications show a compensating differential from 9% to 12% of income, broadly consistent with our main results. The estimates of  $\gamma_1$ , however, do not show any evidence in any of the samples of an hours differential that is significant at the 95% level. This result for individuals with paid jobs suggests that much of the decline in hours that we observe in the main sample is driven by the extensive margin decision of whether to work.

In the results from the preferred specification restricted to workers, shown in Table 10, we continue to observe a compensating differential. Interestingly, our compensating differential findings do not appear to be driven exclusively by individuals who switch ESHI status by changing jobs — we still estimate a compensating differential when we only use variation from individuals who switch ESHI status within the same job. In all three samples, the penalty-and-subsidy-inclusive valuation is smaller in the level specifications and larger in the log specifications. The ratio of the deadweight loss of mandate-based health reform to the deadweight loss of tax-based health reform varies from 4.2% to 18.5% across all six specifications, and the largest upper bound of the 95% confidence interval is 29%.

Overall, our results that include only the intensive margin decision are consistent with our main results, suggesting that the extensive margin decision of whether to work does not drive our

results. Unfortunately, our model does not allow us to examine extensive margin decisions directly. Within our model, we cannot redefine  $L$  as an indicator variable for having a paid job, because all individuals with ESHI must have a paid job, so equilibrium  $D$  would always be above equilibrium  $F$ . If we instead aggregate our data, defining  $L$  as the fraction of individuals with a paid job, we cannot take advantage of longitudinal variation.

## 7.6 Implications for National Reform

We have shown that our model applies to both the Massachusetts and national reforms because they share the same key features. The model shows that mandate-based health reform can be more efficient than tax-based health reform, and we find empirical evidence confirming the model for Massachusetts. Using our results from Massachusetts, we can predict the likely impact of national reform, subject to some caveats.

First, although the Massachusetts and national reforms share the same key features, the statutory values of the policy parameters differ. We have already demonstrated that our main result that mandate-based reform is much more efficient than tax-based reform holds if we increase the employer penalty to the statutory level in national reform, increasing labor market distortion. Our result will also be robust to the larger statutory values of the individual penalty in national reform because the individual penalty increases the penalty-and-subsidy-inclusive valuation, decreasing distortion. Subsidies in national reform are somewhat larger and extend to a larger population because incomes are lower outside of Massachusetts and subsidy thresholds are higher under national reform. Larger subsidies increase labor market distortion. Although the extension of our model in Online Appendix OA1 clearly demonstrates the impact of varying subsidy amounts on welfare, we are not able to separately identify behavioral responses to different subsidy amounts because our cell sizes are so small.<sup>17</sup>

A second caveat in applying our results to national reform is that our model has treated a firm's decision to offer health insurance as exogenous. We do not extend the model to incorporate the firm's decision to offer health insurance because we do not observe whether a firm offers health insurance in our data — we only observe ESHI for individuals who have it. To the extent that firms respond differently to national reform than they do to Massachusetts reform, our results might not generalize.

Furthermore, there could be general equilibrium changes to the health insurance markets under national reform that our analysis of the Massachusetts reform does not capture. For example, compliance with the reform in Massachusetts was high, mitigating adverse selection in the market for health insurance outside of employment (see Hackmann et al. (2012) for evidence of adverse selection in Massachusetts). Suppose that compliance with national reform is not as high, leaving higher prices in the market for health insurance outside of employment. In terms of our model, although adverse selection in the non-employer-sponsored market should not affect the cost of

---

<sup>17</sup>Rather than relying on our estimates from Massachusetts, we could use our model and exclusively calibrate values to predict the impact of national reform. However, without a separate estimate for  $\alpha$ , this approach requires very strong assumptions.

health insurance to employers  $b$ , it could affect the value of a dollar of ESHI relative to a dollar of wages  $\alpha$  because employees will value ESHI more if their outside health insurance option is more expensive. In that case, more adverse selection in the national non-employer-sponsored market could actually decrease the reform-induced distortion to the labor market relative to what we observed in Massachusetts.

Another issue in applying our results to national reform is that we only consider the welfare impact of health reform through distortions to the labor market. Requiring individuals to purchase health insurance through mandate-based reform or providing it to them directly through a tax-based reform also distorts the market for goods and services by requiring individuals to allocate more dollars to health insurance and fewer dollars to other goods. Our welfare analysis starts from the standpoint that policy makers want to expand coverage to near-universal levels and then examines the efficiency of mandate-based reform and tax-based reform in achieving that policy goal. Because mandate-based reform and tax-based reform would result in the same distortion to the product market, when we compare them, we do not need to take product market distortions into account when we analyze the Massachusetts or national reforms. However, if we choose to examine the welfare-impact of mandate-based reform alone, we need to consider that distortions to the market for goods and services create an additional welfare loss. Because Massachusetts started with a higher level of coverage than the rest of the nation, distortions to the market for goods and services could be larger under national reform than they were under the Massachusetts reform. Furthermore, the individual penalty under Massachusetts reform is smaller than the individual penalty under national reform. We have shown that the distortion to the labor market should be greater under the smaller Massachusetts individual penalty; however, the larger national individual penalty could increase distortion to the market for goods and services by providing a larger incentive for individuals to substitute health insurance for other goods.

Finally, in comparing mandate-based health reform to tax-based health reform, we have assumed that mandate-based policy makes the linkage between taxes and benefits more salient — workers can recognize the link between ESHI and wages under mandate-based health reform, but they do not recognize the link between tax-financed health insurance and wages under tax-based reform. In this light, our theory demonstrates that if individuals recognize the linkage between the taxes they pay and the benefits that they receive, and if they value those benefits, then the labor market distortion is smaller than it would be otherwise. Our theory can be applied in a variety of other contexts in which the salience of the linkage between costs and benefits varies. Our results from health reform in Massachusetts suggest that individuals did recognize the linkage between wages and health insurance and that they placed some value on the health insurance that they received. If individuals outside of Massachusetts place a larger value on health insurance, the labor market distortion could be smaller under national reform than it was under the Massachusetts reform.

## 8 Conclusion

The recent Massachusetts and national health reforms are the most profound changes to health policy in the United States since the introduction of Medicare and Medicaid in 1965. Since employers sponsor the majority of health insurance coverage for the non-elderly in the United States, changes to health policy can affect the labor market profoundly. To study the relationship between health reform and the labor market, we develop a model that incorporates the three key elements of mandate-based health reform: employer and individual pay-or-play mandates and expansions in subsidized coverage. Using our model, we characterize the compensating differential for ESHI. We also characterize the welfare impact of the labor market distortion induced by health reform in terms of a small number of sufficient statistics that can be recovered from labor market outcomes. Our model accounts for the complex set of underlying preferences for insurance, capturing them simply as the willingness to trade off monetary wages for employer-sponsored health insurance coverage. Using variation from the Massachusetts reform — which includes the same mandate-based reform elements as the national reform, we estimate our model using longitudinal data from the Survey of Income and Program Participation.

We find evidence of a substantial compensating differential for ESHI: full-time workers that gained coverage due to the Massachusetts reform earned wages that were lower than they would have been had they not gained ESHI by \$6,055 per year, nearly the entire average cost of their health insurance to their employers. Our finding stands in stark contrast to the results from the extensive literature that searches for a compensating differential for ESHI but does not find one. Because of difficulties with identification, studies generally find that individuals with ESHI have *higher* wages than those without. A small number of studies do find evidence in favor of a compensating differential, showing that wages for workers with ESHI decrease as health insurance costs increase. However, these studies use variation in *incremental changes* in the cost of health insurance. We identify the compensating differential using variation in the *entire* cost of health insurance using reform-induced exogenous transitions into and out of ESHI.

Building on our estimated compensating differential, we estimate the welfare impact of the labor market distortion induced by health reform. Our large estimated compensating differential indicates that individuals who gained ESHI were willing to accept lower wages because they valued the coverage that they received. We estimate that individuals who gained coverage through their employers valued approximately 76 cents of every dollar that their employers spent on their coverage. Because individuals valued ESHI, mandate-based health reform in Massachusetts resulted in significantly less distortion to the labor market than it would have otherwise. We estimate that if the government had instead increased insurance coverage by establishing a wage tax to pay for health insurance, the distortion to the labor market would have been more than 20 times as large. Our results suggest that mandate-based reform has the potential to be a very efficient approach for expanding health insurance coverage nationally.

## A Appendix: Massachusetts and National Reform Comparison

Table A1: Summary of Labor Market Provisions in Massachusetts and National Reforms

	<b>Massachusetts Health Care Reform, April 2006</b>	<b>Patient Protection and Affordable Care Act (PPACA), March 2010</b>
“Large” Employer	At least 11 employees <sup>1,2</sup>	At least 50 full-time employees <sup>3</sup>
Provisions Affecting Large Employers	<p>Must either:</p> <ul style="list-style-type: none"> <li>Offer employees the option to purchase health coverage,<sup>5</sup> OR</li> <li>Pay an annual penalty per employee<sup>1</sup></li> </ul> <p>In addition, employers:</p> <ul style="list-style-type: none"> <li>Must offer the option to pay the premium using pre-tax wages<sup>5</sup></li> <li>Are not required to contribute towards the premium (but may pay penalties if they do not)<sup>5</sup></li> </ul>	<p>Must either:</p> <ul style="list-style-type: none"> <li>Offer employees affordable health coverage options,<sup>4</sup> OR</li> <li>Pay an annual penalty per employee<sup>3</sup></li> </ul> <p>Affordable coverage defined as:</p> <ul style="list-style-type: none"> <li>Insurance coverage at least 60% of covered expenses,<sup>3</sup> AND</li> <li>Employees not required to pay more than 9.5% of family income for coverage<sup>3,4</sup></li> </ul>
“Small” Employer	Fewer than 11 employees	Fewer than 50 employees
Provisions Affecting Small Employers	<p>May purchase coverage for employees via the Commonwealth Health Insurance Connector, which:<sup>1</sup></p> <ul style="list-style-type: none"> <li>Offers access to health insurance options approved by a State board</li> <li>Merges the individual and small business insurance markets</li> </ul>	<p>Very small businesses (fewer than 25 employees) may:</p> <ul style="list-style-type: none"> <li>Be eligible for a tax credit for offering health insurance if average wages are under \$50,000<sup>3,4</sup></li> </ul>
Penalties (Large Employers)	<p>Must pay a penalty of \$295 per employee per year, if:</p> <ul style="list-style-type: none"> <li>The employer does not offer health insurance options,<sup>1</sup> OR</li> <li>The employer contributes less than 33% of the premium<sup>2</sup></li> </ul> <p>Must also pay a penalty if employees use the uncompensated care pool<sup>2</sup></p>	<p>Two types of penalties:</p> <ul style="list-style-type: none"> <li>Must pay \$2,000 per full-time employee for not offering <b>any</b> insurance options<sup>3,4</sup></li> <li>Must pay \$3,000 (up to a maximum) for not offering affordable coverage, for all employees receiving a tax credit for insurance purchased on exchange<sup>3,4</sup></li> </ul> <p>Penalties increase annually for premium growth. Not assessed for first 30 employees<sup>3,4</sup></p>
Provisions Affecting Individuals	<p>Individuals are required either to:</p> <ul style="list-style-type: none"> <li>Buy creditable health insurance,<sup>1,7</sup> OR</li> <li>Pay a penalty, if the cost of coverage has been deemed affordable<sup>6,7</sup></li> </ul> <p>Individuals with incomes below 300% of poverty can access subsidized health insurance:<sup>7</sup></p> <ul style="list-style-type: none"> <li>&lt;150% of poverty pay no premium<sup>1</sup></li> <li>151-200% pay \$35 per month<sup>1</sup></li> <li>Up to 300% receive subsidies</li> </ul>	<p>Individuals are required either to:</p> <ul style="list-style-type: none"> <li>Purchase “qualifying” health coverage,<sup>8</sup> OR</li> <li>Pay a penalty, with some exemptions available<sup>8</sup></li> </ul> <p>Provides subsidies/access to coverage for low-income individuals:</p> <ul style="list-style-type: none"> <li>&lt;133% of poverty become eligible for Medicaid coverage, effectively 138% after deducting 5% of poverty<sup>8,9</sup></li> <li>Up to 400% receive premium/cost-sharing credits towards purchase via the exchanges. Credits increase with income, limiting contributions from 2% to 9.5% of income<sup>8</sup></li> </ul>
Penalties (Individuals)	<p>Individuals who do not purchase affordable coverage, but are in income brackets with affordable coverage available, face penalties:<sup>7</sup></p> <ul style="list-style-type: none"> <li>Initially, \$219 per individual</li> <li>Starting in 2008, up to 50% of the cost of the least expensive coverage</li> </ul>	<p>Individuals not purchasing coverage face a penalty of the greater of:</p> <ul style="list-style-type: none"> <li>\$695 (annually) to a maximum of three times this amount,<sup>8</sup> OR</li> <li>2.5% of household income<sup>8</sup></li> </ul> <p>These amounts phased in beginning in 2014<sup>8</sup></p>

## OA1 Online Appendix: Variation in Subsidy Amounts

We can extend our model to incorporate variation in the health insurance subsidy amounts that Massachusetts and ACA extend to subsets of the population. Thus far, we have modeled these subsidies as a share of the total cost of health insurance,  $\mu_x$ , that is paid by the government. The subscript  $x$  indexes the magnitude of the subsidy, which varies based on income. Here, we specify three different income categories as values of  $x$ :  $I$  for the income category that is not eligible for any subsidies,  $II$  for the income category that is eligible for partial subsidies, and  $III$  for the income category that is eligible for full subsidies. Before reform, some individuals receive subsidies  $\mu_{III}$ . After reform, some individuals receive fully subsidized coverage, and others with higher incomes receive partial subsidies  $\mu_{II}$ . Individuals in the highest income categories do not qualify for any subsidies; therefore,  $\mu_I = 0$ .

As in the case of the individual mandate, the subsidies only affect an individual's labor supply if he *does* obtain health insurance through his employer. In the face of a penalty, he is *more* willing to work for health benefits instead of wages. However, if he is eligible for a subsidy for health insurance outside of employment, he is *less* willing to work for employer health insurance benefits instead of wages.<sup>1</sup>

Figure OA1: Graphical Model with Variation in Subsidy Amounts

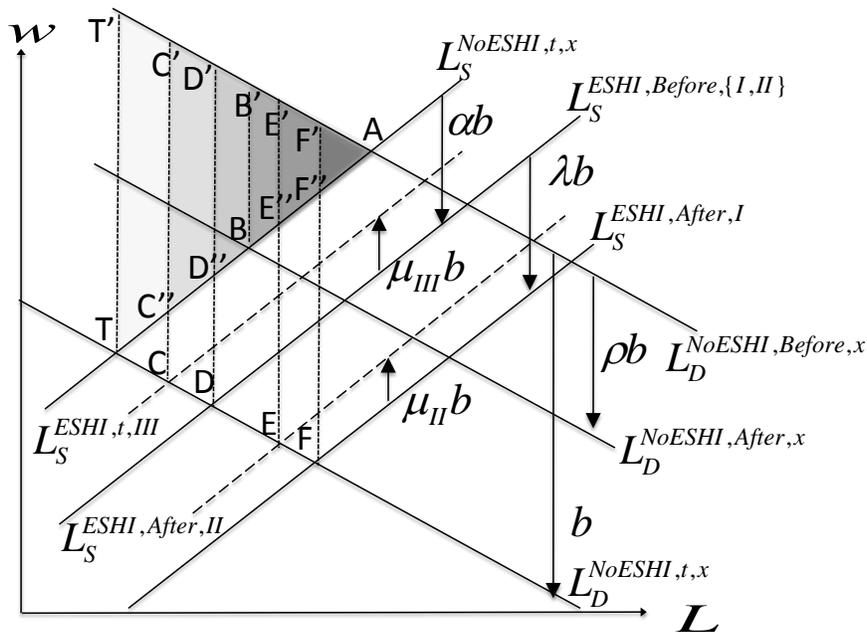

Figure OA1 shows the graphical model that incorporates variation in the subsidy amounts. Individuals who are eligible for a full subsidy but forgo it for ESHI before the reform have wages and hours given by  $C$ . They remain at  $C$  after the reform because the individual penalty does not

<sup>1</sup>This discussion assumes that health insurance does not affect an individual's ability to work. To the extent that it does, we could introduce separate  $L_S^{NoESHI}$  curves for individuals with and without any health insurance. We are unlikely to have enough variation to separate these two curves in our empirical implementation.

apply to them. Individuals who become eligible for a partial subsidy but forgo it for ESHI after the reform have wages and hours given by point  $E$ . Individuals with ESHI who are not eligible for any subsidies after the reform have wages and hours given by point  $F$ . The other equilibria are unchanged from the original model.

Figure OA1 incorporates the universe of equilibria under mandate-based health reform with three separate subsidy eligibility categories. There are six possible labor market equilibria ( $A$  through  $F$ ) depicted, which depend on ESHI status and the values of the parameters. However, for any given individual, there are only four possible equilibria - equilibria with and without ESHI before and after reform. The first two columns of Table OA1 list the four relevant equilibria for each category of subsidy eligibility.

Table OA1: Wages in Terms of Coefficients by Subsidy Amounts

I: 300 FPL+

$w_{BIII}$	noeshi, after	$\beta_6 + \beta_{11}$
$w_{CIII}$	eshi, before	$\beta_4 + \beta_8 [+ \beta_{4e} + \beta_{8e}]$
$w_{EIII}$	eshi, after	$\beta_1 + \beta_2 + \beta_4 + \beta_6 + \beta_8 + \beta_{11} [+ \beta_{1e} + \beta_{2e} + \beta_{4e} + \beta_{8e}]$

### OA1.1 Identification

For identification of the additional parameters, we incorporate variation across subsidy eligibility categories. Table OA2 presents all of the sufficient statistics in terms of differences between equilibria. Within each subsidy eligibility category, we can estimate all possible sufficient statistics from the original model. For example, we can derive the slope of the supply curve within each of the three eligibility categories, resulting in sufficient statistics  $s_I$ ,  $s_{II}$ , and  $s_{III}$ , as shown in the first three rows of the table. As drawn, our graphical model assumes that the slopes of the labor supply curves are the same within each category. We can test the assumption by allowing the slopes to vary within each eligibility category. We can identify all sufficient statistics identified by the main

model, discussed in Section 4 of the paper, using the same variation in the extended model.

Table OA2: Sufficient Statistics in Terms of Differences between Equilibria by Subsidy Amounts

Sufficient statistic	Expression in wages and employment
$s_I$	$\frac{w_{BI}-w_{AI}}{L_{BI}-L_{AI}}$
$s_{II}$	$\frac{w_{BII}-w_{AII}}{L_{BII}-L_{AII}}$
$s_{III}$	$\frac{w_{BIII}-w_{AIII}}{L_{BIII}-L_{AIII}}$
$d_I$	$\frac{w_{FI}-w_{DI}}{L_{FI}-L_{DI}}$
$d_{II}$	$\frac{w_{EII}-w_{DII}}{L_{EII}-L_{DII}}$
$d_{III}$	$\frac{w_{CIII}-w_{DIII}}{L_{CIII}-L_{DIII}}$
$\rho_I$	$\frac{d_I(L_{BI}-L_{AI})-(w_{BI}-w_{AI})}{b}$
$\rho_{II}$	$\frac{d_{II}(L_{BII}-L_{AII})-(w_{BII}-w_{AII})}{b_{II}}$
$\rho_{III}$	$\frac{d_{III}(L_{BIII}-L_{AIII})-(w_{BIII}-w_{AIII})}{b_{III}}$
$b_I$	$d_I(L_{FI} - L_{AI}) - (w_{FI} - w_{AI})$
$b_{II}$	$d_{II}(L_{EII} - L_{AII}) - (w_{EII} - w_{AII})$
$b_{III}$	$d_{III}(L_{CIII} - L_{AIII}) - (w_{CIII} - w_{AIII})$
$\alpha_I$	$\frac{s(L_{DI}-L_{AI})-(w_{DI}-w_{AI})}{b_I}$
$\alpha_{II}$	$\frac{s_{II}(L_{DII}-L_{AII})-(w_{DII}-w_{AII})}{b_{II}}$
$\lambda_I$	$\frac{s(L_{FI}-L_{DI})-(w_{FI}-w_{DI})}{b_I}$
$\alpha_I + \lambda_I$	$\frac{s(L_{FI}-L_{AI})-(w_{FI}-w_{AI})}{b_I}$
$\alpha_{II} + \lambda_I - \mu_{II}$	$\frac{s_{II}(L_{EII}-L_{AII})-(w_{EII}-w_{AII})}{b_{II}}$
$\alpha_I - \mu_{III}$	$\frac{s_{III}(L_{CIII}-L_{AIII})-(w_{CIII}-w_{AIII})}{b_{III}}$
$\mu_{III}$	$\alpha_I - \frac{s_{III}(L_{CIII}-L_{AIII})-(w_{CIII}-w_{AIII})}{b_{III}}$
$\mu_{II}$	$\alpha_{II} + \lambda_I - \frac{s_{II}(L_{EII}-L_{AII})-(w_{EII}-w_{AII})}{b_{II}}$

In addition, we can separately identify the subsidy parameters from the other parameters by comparing across categories. For example, to identify  $\mu_{III}$ , we first identify  $\alpha - \mu_{III}$  by comparing individuals who are eligible for full subsidies who move from not having ESHI before the reform (equilibrium A) to having ESHI after the reform (equilibrium C). Next, we net this sum out of the value of  $\alpha$  obtained from the category that is not eligible for any subsidies. We identify  $\mu_{II}$  with a similar comparison across categories. We do note, however, that separate identification of each  $\mu_x$  requires the assumption that  $\alpha$  does not vary by subsidy eligibility group. Were we to relax that assumption, as we do in the pooled estimation in Section 7.4, we cannot separately identify subsidy effects from differences in the underlying valuation.

## OA1.2 Estimation

To estimate all of the relevant parameters of our model, we specify and estimate wage and hours equations of the following form:

$$Y_{it} = [\beta_1 MA * ESHI * After * Large + \beta_2 MA * ESHI * 1(< 150FPL) * After * Large +$$

$$\begin{aligned}
& \beta_3 MA * ESHI * 1(150to300FPL) * After * Large + \beta_4 MA * ESHI * 1(< 150FPL) * Large + \\
& \beta_5 MA * ESHI * 1(150to300FPL) * Large + \beta_6 MA * 1(< 150FPL) * After * Large + \\
& \beta_7 MA * 1(150to300FPL) * After * Large + \beta_8 MA * ESHI * Large + \\
& \beta_9 MA * 1(< 150FPL) * Large + \beta_{10} MA * 1(150to300FPL) * Large + \\
& \beta_{11} MA * After * Large + \beta_{12} ESHI * After * Large + \\
& \beta_{13} ESHI * 1(< 150FPL) * After * Large + \beta_{14} ESHI * 1(150to300FPL) * After * Large + \\
& \beta_{15} ESHI * 1(< 150FPL) * Large + \beta_{16} ESHI * 1(150to300FPL) * Large + \\
& \beta_{17} 1(< 150FPL) * After * Large + \beta_{18} 1(150to300FPL) * After * Large + \\
& \beta_{19} ESHI * Large + \beta_{20} 1(< 150FPL) * Large + \beta_{21} 1(150to300FPL) * Large + \beta_{22} After * Large + \\
& \beta_{23} large + \phi_g * Large + ] \\
& \beta_{1[e]} MA * ESHI * After + \beta_{2[e]} MA * ESHI * 1(< 150FPL) * After + \\
& \beta_{3[e]} MA * ESHI * 1(150to300FPL) * After + \beta_{4[e]} MA * ESHI * 1(< 150FPL) + \\
& \beta_{5[e]} MA * ESHI * 1(150to300FPL) + \beta_{6[e]} MA * 1(< 150FPL) * After + \\
& \beta_{7[e]} MA * 1(150to300FPL) * After + \beta_{8[e]} MA * ESHI + \\
& \beta_{9[e]} MA * 1(< 150FPL) + \beta_{10[e]} MA * 1(150to300FPL) + \\
& \beta_{11[e]} MA * After + \beta_{12[e]} ESHI * After + \\
& \beta_{13[e]} ESHI * 1(< 150FPL) * After + \beta_{14[e]} ESHI * 1(150to300FPL) * After + \\

& \beta_{19[e]} ESHI + \{\beta_{20[e]} 1(< 150FPL)\} + \{\beta_{21[e]} 1(150to300FPL)\} + \beta_{22[e]} After + \\
& \phi_g + \delta_i + \varepsilon_{it}
\end{aligned}$$

where all of the terms are as defined in the main estimating equation, which is a special case of this equation. Because our data do not include information on subsidy eligibility, we proxy for subsidy eligibility with income categories. We assume that people above 300% of the federal poverty line (FPL) are not eligible for any subsidies before or after reform. People between 150 and 300% of FPL are eligible for partial subsidies after the reform, and we represent them with the indicator  $1(150to300FPL)$ . People under 150% of FPL are eligible for full subsidies before and after the reform, and we represent them with the indicator  $1(< 150FPL)$ . We classify individuals into income groups using the first period of available data to avoid regressing wages on contemporaneous measures of income. Therefore,  $\beta_{20e}$  and  $\beta_{21e}$  are shown in  $\{\}$  and omitted because they are collinear with the individual fixed effects. From the estimated coefficients, we can derive each of the sufficient statistics as shown in Table OA3.

Table OA3: Sufficient Statistics in Terms of Coefficients by Subsidy Amounts

Sufficient statistic	Expression in coefficients
$s_I$	$\frac{\beta_{11}}{\gamma_{11}}$
$s_{II}$	$\frac{\beta_7 + \beta_{11}}{\gamma_7 + \gamma_{11}}$
$s_{III}$	$\frac{\beta_6 + \beta_{11}}{\gamma_6 + \gamma_{11}}$
$d_I$	$\frac{\beta_1 + \beta_{11} + \beta_{1e}}{\gamma_1 + \gamma_{11} + \gamma_{1e}}$
$d_{II}$	$\frac{\beta_1 + \beta_3 + \beta_7 + \beta_{11} + \beta_{1e} + \beta_{3e}}{\gamma_1 + \gamma_3 + \gamma_7 + \gamma_{11} + \gamma_{1e} + \gamma_{3e}}$
$d_{III}$	$\frac{\beta_1 + \beta_2 + \beta_6 + \beta_{11} + \beta_{1e} + \beta_{2e}}{\gamma_1 + \gamma_2 + \gamma_6 + \gamma_{11} + \gamma_{1e} + \gamma_{2e}}$
$\rho_I$	$\frac{b_I}{d_I(\gamma_{11}) - (\beta_{11})}$
$\rho_{II}$	$\frac{d_{II}(\gamma_7 + \gamma_{11}) - (\beta_7 + \beta_{11})}{b_{II}}$
$\rho_{III}$	$\frac{d_{III}(\gamma_6 + \gamma_{11}) - (\beta_6 + \beta_{11})}{b_{III}}$
$b_I$	$d_I(\gamma_1 + \gamma_8 + \gamma_{11} + \gamma_{1e} + \gamma_{8e}) - (\beta_1 + \beta_8 + \beta_{11} + \beta_{1e} + \beta_{8e})$
$b_{II}$	$d_{II}(\gamma_1 + \gamma_3 + \gamma_5 + \gamma_7 + \gamma_8 + \gamma_{11} + \gamma_{1e} + \gamma_{3e} + \gamma_{5e} + \gamma_{7e} + \gamma_{8e}) - (\beta_1 + \beta_3 + \beta_5 + \beta_7 + \beta_8 + \beta_{11} + \beta_{1e} + \beta_{3e} + \beta_{5e} + \beta_{7e} + \beta_{8e})$
$b_{III}$	$d_{III}(\gamma_1 + \gamma_2 + \gamma_4 + \gamma_6 + \gamma_8 + \gamma_{11} + \gamma_{1e} + \gamma_{2e} + \gamma_{4e} + \gamma_{8e}) - (\beta_1 + \beta_2 + \beta_4 + \beta_6 + \beta_8 + \beta_{11} + \beta_{1e} + \beta_{2e} + \beta_{4e} + \beta_{8e})$
$\alpha_I$	$\frac{b_I}{s_I(\gamma_8 + \gamma_{8e}) - (\beta_8 + \beta_{8e})}$
$\alpha_{II}$	$\frac{b_{II}}{s_{II}(\gamma_5 + \gamma_8 + \gamma_{5e} + \gamma_{8e}) - (\beta_5 + \beta_8 + \beta_{5e} + \beta_{8e})}$
$\lambda_I$	$\frac{b_{II}}{s_I(\gamma_1 + \gamma_{11} + \gamma_{1e}) - (\beta_1 + \beta_{11} + \beta_{1e})}$
$\alpha_I + \lambda_I$	$\frac{b_I}{s_I(\gamma_1 + \gamma_8 + \gamma_{11} + \gamma_{1e} + \gamma_{8e}) - (\beta_1 + \beta_8 + \beta_{11} + \beta_{1e} + \beta_{8e})}$
$\alpha_{II} + \lambda_I - \mu_{II}$	$\frac{b_I}{s_{II}(\gamma_1 + \gamma_3 + \gamma_5 + \gamma_7 + \gamma_8 + \gamma_{11} + \gamma_{1e} + \gamma_{3e} + \gamma_{5e} + \gamma_{7e} + \gamma_{8e}) - (\beta_1 + \beta_3 + \beta_5 + \beta_7 + \beta_8 + \beta_{11} + \beta_{1e} + \beta_{3e} + \beta_{5e} + \beta_{7e} + \beta_{8e})}$
$\alpha_I - \mu_{III}$	$\frac{b_{II}}{s_{III}(\gamma_1 + \gamma_2 + \gamma_4 + \gamma_6 + \gamma_8 + \gamma_{11} + \gamma_{1e} + \gamma_{2e} + \gamma_{4e} + \gamma_{8e}) - (\beta_1 + \beta_2 + \beta_4 + \beta_6 + \beta_8 + \beta_{11} + \beta_{1e} + \beta_{2e} + \beta_{4e} + \beta_{8e})}$
$\mu_{III}$	$\alpha_I - \frac{b_{III}}{s_{III}(\gamma_1 + \gamma_2 + \gamma_4 + \gamma_6 + \gamma_8 + \gamma_{11} + \gamma_{1e} + \gamma_{2e} + \gamma_{4e} + \gamma_{8e}) - (\beta_1 + \beta_2 + \beta_4 + \beta_6 + \beta_8 + \beta_{11} + \beta_{1e} + \beta_{2e} + \beta_{4e} + \beta_{8e})}$
$\mu_{II}$	$\alpha_{II} + \lambda_I - \frac{b_{II}}{s_{II}(\gamma_1 + \gamma_3 + \gamma_5 + \gamma_7 + \gamma_8 + \gamma_{11} + \gamma_{1e} + \gamma_{3e} + \gamma_{5e} + \gamma_{7e} + \gamma_{8e}) - (\beta_1 + \beta_3 + \beta_5 + \beta_7 + \beta_8 + \beta_{11} + \beta_{1e} + \beta_{3e} + \beta_{5e} + \beta_{7e} + \beta_{8e})}$

### OA1.3 Results

We present results from the preferred specification with firm size interaction terms in Table OA4. Following our main approach, we calibrate  $s$  and  $d$  in each category. We also calibrate  $\rho$  as above in computing our measures of deadweight loss. Our estimates are very noisy, illustrating the advantage of pooling all income categories in our main specifications. Despite the noise, some patterns emerge.

Combining the compensating and hours differential estimates with calibrated labor supply and demand slopes yields estimates for  $b$  that are correctly signed. Our estimates for  $b_I$  and  $b_{III}$  are \$1.13 and \$2.50 per hour, respectively. The estimate for  $b_{II}$ , however, is \$15.55. This does not accord well with the cost of ESHI. This is a first indication that estimated effects for this group likely reflect the relatively small sample size for individuals between 150% of FPL and 300% of FPL in Massachusetts in the SIPP. Because the SIPP over samples among the poor, sample size is not a problem for the population who qualify for full subsidies,  $\mu_{III}$ . We also have sufficient observations for income category  $I$ , given the large share of the population earning more than 300% of FPL.

Translating our estimates for the compensating and hours differentials into penalty-and-subsidy-inclusive valuations, we find relatively high estimates for all groups. To maintain internal consistency by group, the penalty-and-subsidy-inclusive valuation for each group is taken relative to the estimated cost of  $b$  for that group. All of the estimates are of a reasonable magnitude, though we note that only  $\alpha_I - \mu_{III}$  and  $\alpha_I + \lambda_I$  are significantly different from zero. The estimates suggest a relatively high penalty-and-subsidy-inclusive valuation across subsidy levels. In fact, the estimate of  $\alpha_I + \lambda_I$  is not significantly different from 1. These findings suggest that the behavioral response to qualifying for a subsidy is not a strong driver of reduced valuation for ESHI. However, given the noisy estimates, particularly for those who qualify for partial subsidies, we do not emphasize the precision of this conclusion.

Turning to our separate estimates for each of the  $\mu_x$  terms, which are not identified as convincingly, we do not find compelling estimates. Our estimate for  $\mu_{III}$ , corresponding to a full subsidy, is -2.56. This estimate is both of the wrong sign and far larger than we would predict given that it is measured as a share of the cost of the benefit,  $b$ . The estimate for  $\mu_{II}$  has the expected sign but is also larger than we would expect, given that  $\mu_{II}$  is only a partial subsidy.

As in our earlier estimates, we are still able to compute aggregate measures for the cost of ESHI and the penalty-and-subsidy-inclusive valuation, even if the separate parameters are not measured well. Therefore, we can still compute the deadweight loss of mandated-based reform for each of the groups who qualify for different subsidies. Our estimates for the deadweight loss associated with mandate-based reform for group  $I$  and  $III$  are substantially smaller than our estimates in the aggregate population. The estimated deadweight loss of mandate-based reform for the partial subsidy group, on the other hand, is much larger. We find that the annual deadweight loss of mandate-based reform ( $DWL_m$ ) for individuals eligible for no, partial, and full subsidies is \$0.57, \$355 and \$0.26, respectively. We are also able to compute the relative deadweight loss of mandate-based reform compared to tax-based reform for each of the subsidy eligible groups. The estimated deadweight loss of mandate-based reform is 1%, 3.2%, and 0.1% of tax based reform for groups

*I*, *II*, and *III*, respectively. These findings suggest that our main deadweight loss findings are broadly robust to subgroup specific estimates, though we note that group *II* in particular seems to have very noisy estimates.

Taken together, these results, which allow for different responses for individuals who qualify for different subsidies, are consistent with our main findings. Because these specifications allow us to identify additional parameters, specifically the magnitude of the behavioral response to qualifying for subsidized health insurance outside of an employer, we could use these estimates as our main specification. However, we do not emphasize these results because we lose a considerable amount of power when we further divide the SIPP data into income categories.

# Outsourcing at Will: The Contribution of Unjust Dismissal Doctrine to the Growth of Employment Outsourcing

David H. Autor, *Massachusetts Institute of Technology and the National Bureau of Economic Research*

Over the past 3 decades, the U.S. Temporary Help Services (THS) industry grew five times more rapidly than overall employment. Contemporaneously, courts in 46 states adopted exceptions to the common law doctrine of employment at will that limited employers' discretion to terminate workers and opened them to litigation. This article assesses the contribution of "unjust dismissal" doctrine to THS employment specifically, and outsourcing more generally, finding that it is substantial—explaining 20% of the growth of THS between 1973 and 1995 and contributing 500,000 additional outsourced workers in 2000. States with smaller declines in unionization also saw substantially more THS growth.

Between 1979 and 1995, the Temporary Help Supply (THS) industry in the United States grew at 11% annually—over five times more rapidly

This article was previously titled "Outsourcing at Will: Unjust Dismissal Doctrine and the Growth of Temporary Help Employment." I am indebted to Daron Acemoglu, Joshua Angrist, John Donohue III, Edward Glaeser, Susan Houseman, Alan Hyde, John H. Johnson III, Lawrence Katz, Sendhil Mullainathan, Andrew Morriss, Richard Murnane, Stewart Schwab, Douglas Staiger, and Marika Tatsutani for valuable suggestions, and to Barry Guryan of Epstein, Becker, and Green for expert legal counsel. I also thank seminar participants at University of California, Berkeley, Brown University, Harvard University, the Massachusetts Institute of Technology, the National Bureau of Economic Research Labor Studies workshop, the University of Maryland, and the 2000 Econometrics Society meeting for their comments.

NOTE.—Percentage of nonfarm employment appears below employment count.

than U.S. nonfarm employment—and increased its daily head count from 435,000 to 2.4 million workers (table 1). During these same years, what many have termed a revolution in jurisprudence toward worker dismissal occurred as U.S. state courts recognized exceptions to the common law doctrine of employment at will. That doctrine, which had been recognized throughout the United States by 1953, held that employers and employees have unlimited discretion to terminate their employment relationships at any time for any reason unless explicitly contracted otherwise. The recognition of exceptions to employment at will by 46 state courts between 1973 and 1995 limited employers' discretion to terminate workers and opened them to potentially costly litigation.<sup>1</sup> This article assesses whether these contemporaneous phenomena—the erosion of employment at will and the rapid growth of THS—are causally related. More generally, the article answers the question of whether changes to the legal environment surrounding worker dismissal are in part responsible for the growth of “contingent” work arrangements in the U.S. economy, the most prominent example of which is temporary help employment. The answer appears to be yes.

The analysis proceeds as follows: Section I introduces the three classes of common law exception to the at-will doctrine, evaluates their impli-

<sup>1</sup> Of course, employers' power to terminate at will has not been absolute for some time. Major pieces of federal legislation that protect the employment rights of minorities, union members, persons over the age of 40, and persons with disabilities include Title VII of the Civil Rights Act of 1964, the Civil Rights Act of 1991, the National Labor Relations Act, the Age Discrimination in Employment Act of 1967, and the Americans with Disabilities Act of 1992.

cations for THS and other “outsourced” employment, and concludes that one exception in particular—the implied contractual right to continued employment (“implied contract”)—provides a compelling incentive for firms to utilize temporary help workers. Section II considers a simple model of employment outsourcing in the presence of positive firing costs. The key implication of the model is that employers are likely to respond to mandated firing costs by outsourcing jobs that require limited firm-specific capital, an implication that aptly describes the occupations typically supplied by THS. Section III describes the data and empirical strategy, and Section IV provides empirical results. Section V concludes.

A key finding of the present analysis is that state courts’ adoption of the implied contract doctrine has resulted in approximately 22% excess temporary help employment growth in adopting states. In addition, states experiencing smaller declines in unionization saw substantially greater THS growth. Unjust dismissal doctrines did not significantly contribute to employment growth in other business service industries, however. In net, the results indicate that changes to the employment-at-will doctrine explain as much as 20% of the growth of THS between 1973 and 1995 and account for 365,000–530,000 additional workers employed in THS on a daily basis as of 2000.

The present analysis is related to empirical analyses by Dertouzos and Karoly (1992), Morriss (1995), Kugler and Saint-Paul (2000), and Autor, Donohue, and Schwab (2001), who explore the impacts of unjust dismissal doctrine on overall employment levels and growth, job termination probabilities, and job-to-job flows; to recent work evaluating the impacts of civil rights legislation on the employment of the disabled (DeLeire 2000; Acemoglu and Angrist 2001) and minorities (Donohue and Heckman 1991; Oyer and Schaefer 2000, 2002); and to research on the impact of labor-market flexibility on labor force participation, employment, and unemployment in countries in the Organization for Economic Cooperation and Development (OECD; Lazear 1990; Di Tella and MacCulloch 1998; Blanchard and Portugal 2001). Morriss (1995) offers a thorough review of case law affecting employment at will, Epstein (1984) presents the major legal and economic arguments supporting the at-will doctrine, Segal and Sullivan (1997*a*) provide a comprehensive discussion of the growth of THS, and Abraham and Taylor (1996) and Houseman (2001) provide insightful analyses of the determinants of firms’ use of flexible staffing arrangements.

The unique contribution of the current study is to explore theoretically and empirically the impact that unjust dismissal doctrine has had on employment outsourcing. Lee (1996) and Segal and Sullivan (1997*a*) suggest a possible causal connection between the growth of THS and the decline of employment at will but do not investigate the question empirically. In independent contemporaneous work, Miles (2000) explores the impact of

common law exceptions to employment at will on a variety of labor-market aggregates and reports results for temporary help employment that are largely consistent with those presented here.<sup>2</sup>

### I. The Decline of Employment at Will

The employment-at-will doctrine was most famously articulated by the Tennessee Supreme Court in 1884, which wrote that “men must be left, without interference to buy and sell where they please, and to discharge or retain employees at will for good cause or for no cause, or even for bad cause without thereby being guilty of an unlawful act per se” (*Payne v. Western & Atlantic Railroad, Tennessee* 1884). Although largely uncontroversial at the turn of the century, the judicial consensus behind the at-will doctrine eroded rapidly beginning with the publication of an extraordinarily influential law review article by Blades (1967; see Morriss 1994). Prior this time, only one state (California in 1959) had recognized an exception to employment at will. But in the subsequent 2 decades, 44 additional states recognized exceptions, as is shown in figure 1. By 1992, 46 of 50 states had amended the at-will doctrine, in 45 of these cases judicially and in one case legislatively.<sup>3</sup> The tenor of these judicial decisions is exemplified in a court opinion from the 1985 Texas case of *Sabine Pilots, Inc. v. Hauck*: “Absolute employment at will is a relic of early industrial times, conjuring up visions of the sweat shops described by Charles Dickens and his contemporaries. The doctrine belongs in a museum, not in our law.”

By the early 1990s, state courts had recognized three common law exceptions to the at-will relationship: breach of an implied contractual right to continued employment, terminations contrary to public policy, and violations of an implied covenant of good faith and fair dealing. For reasons discussed below, only the first of these exceptions is likely to be relevant to the outsourcing of employment.

<sup>2</sup> Miles (2000) reports a significant impact of both the “implied contract” and “good faith” doctrines on temporary help employment, although it is shown below that only the first of these correlations is likely to be causal. Beyond this area of overlap, the present article explores the economic incentives for firms to outsource employment to THS and considers why the implied contract doctrine apart from other common law exceptions appears relevant to this choice. Additionally, it assesses the contribution of unjust dismissal doctrines and unionization to THS employment and other business services outsourcing.

<sup>3</sup> Montana is the one state that adopted a statute specifically defining a default employment contract other than employment at will, the Montana Wrongful Discharge from Employment Act of 1987. Interestingly, this legislative action may have been a response to a particularly broad incursion into the at-will doctrine by the Montana courts (cf. Krueger 1991; Morriss 1995).

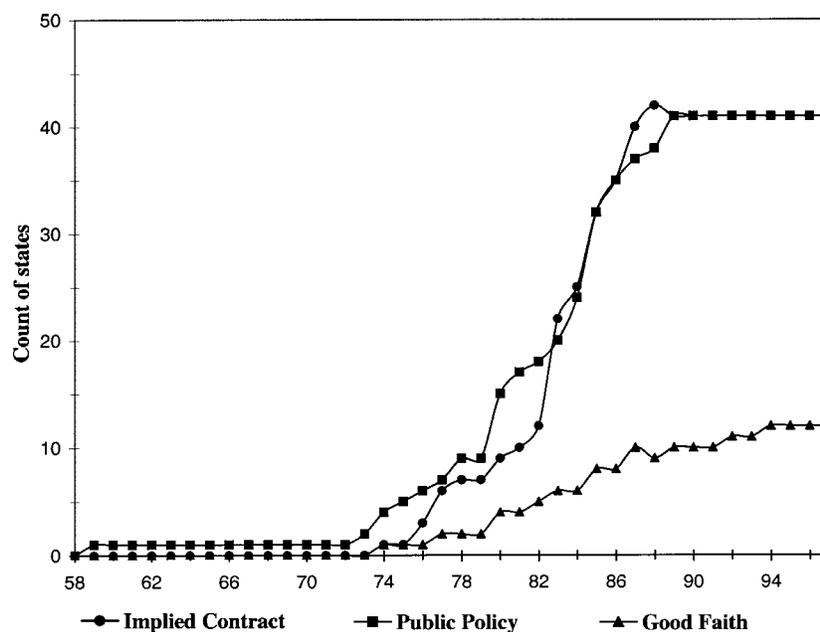

FIG. 1.—Count of states recognizing exceptions to the employment-at-will doctrine, 1958–97.

#### A. The Implied Contract Exception to Employment at Will

A landmark decision in the recent erosion of employment at will is the 1980 case of *Toussaint v. Blue Cross & Blue Shield*, in which the Michigan Supreme Court held that an employer's indirect statements about the manner in which termination decisions are made can imply legally binding employment contracts.<sup>4</sup> In *Toussaint*, the plaintiff successfully sued for breach of contract by citing an internal personnel policy handbook indicating that it was Blue Cross's policy to terminate employees only for just cause. Although Toussaint was unaware of the handbook when hired, the court held that the handbook implied a binding contract. Courts in 23 other states issued similar decisions over the next 5 years. An equally influential 1981 California case, *Pugh v. See's Candies*, further expanded the implied contract notion by finding that workers are entitled to ongoing employment even in the absence of written or indirect statements if contractual rights are implied via the context of the employment relationship. This context may include, for example, longevity of service, a history of promotion or salary increases, general company policies as exemplified

<sup>4</sup> Full citations for precedent setting cases cited in the text are given in table A1.

by treatment of other employees, or typical industry practices. Cumulatively, these court decisions generated substantial uncertainty surrounding termination, resulting in numerous cases where courts found that employees held implied contractual employment rights that employers had clearly not intended to offer.<sup>5</sup>

Systematic data on the costs of unjust dismissal suits are sparse because fewer than 3% of these suits reach a jury, and the vast majority settle (Jung 1997). Among California implied contract actions studied by Jung, plaintiffs prevailed in 52% of cases, with average and median compensatory damages of \$586,000 and \$268,000, respectively. In addition to jury awards, legal fees in the cases studied by Dertouzos, Holland, and Ebener (1988) averaged \$98,000 in cases where the defense prevailed and \$220,000 in cases where the plaintiff prevailed. Underscoring the fact that large transaction costs are the norm, the average net award received by plaintiffs was only 48% of the money changing hands.<sup>6</sup>

Indirect costs are likely to be substantial. The threat of litigation will prompt forward-looking employers to take avoidance actions such as revising employment manuals, limiting the discretion of managers to hire and fire, instigating bureaucratic procedures for documenting and terminating poorly performing employees, and potentially retaining unproductive workers who would otherwise be fired. These steps, while potentially costly, are difficult to quantify.<sup>7</sup> Additionally, since there are no representative data available on the share of terminations leading to unjust dismissal suits, it is not possible to compute a measure of expected direct employer cost.

#### B. Implications of the Implied Contract Exception for Temporary Help Employment

There is substantial evidence that employers were aware of the changing legal environment and responded to it by attempting to “contract around”

<sup>5</sup> A defendant’s attorney interviewed for this research stated that the implied contract doctrine leaves open “the largest room for creativity” on the part of plaintiffs’ attorneys because the definition of what constitutes an indirect or contextual statement of contractual rights is open to broad interpretation (personal communication with Barry Guryan, January 14, 2000).

<sup>6</sup> Figures from Dertouzos et al. (1988, table 16) and Jung (1997) are inflated to 1999 dollars using the Personal Consumption Expenditure deflator. Dertouzos et al. do not provide disaggregated data, and hence these figures apply to all unjust dismissal suits rather than just implied contract suits. Both studies use California data, which is most frequently studied because of the state’s accessible electronic case reporting system.

<sup>7</sup> Lewin (1987) reports that managers implicated by employee complaints of wrongful treatment may also suffer diminished career advancement, even in instances where the complaint is ultimately unsuccessful. This finding suggests that unjust dismissal doctrines may induce agency problems in which risk-averse managers take unduly costly actions (from the firm’s perspective) to avoid litigation.

the implied contract exception. Edelman, Abraham, and Erlanger (1992) document that throughout the 1980s, personnel and professional law journals published a flurry of articles warning employers—often in hyperbolic terms—of the liability risks imposed by unjust dismissal doctrines.<sup>8</sup> The Bureau of National Affairs (1985) found that 63% of employers surveyed in the early 1980s had recently “removed or changed wording in company publications to avoid any suggestion of an employment contract,” and 53% of employers had “added wording to applications and handbooks specifying that employment may be terminated for any reason.” Sutton and Dobbin (1996) also report that the percentage of firms using “at-will” clauses in employment contracts increased from 0% to 29% between 1955 and 1985.

In practice, however, the courts have made it difficult for employers to contract around the risk posed by implied contract suits. For example, courts have ruled that employers’ progressive discipline policies—stipulating that workers will not be fired for poor performance without first receiving successive warnings—demonstrate the intent of an implied contract of ongoing employment. Similarly, courts have taken employers’ 401K and other retirement programs as evidence of an expectation of long-term employment. And in 15 states that currently recognize the implied-contract exception, courts have held that signed disclaimers waiving implied contract rights do not, in fact, nullify these rights (Walsh and Schwarz 1996). Perhaps ironically, courts have also ruled that probationary hiring periods can themselves create an implied contract once the probationary period is complete.<sup>9</sup>

These court decisions have not extended to temporary help, however, which remains a relatively “safe” alternative for employers wishing to avoid termination risks associated with the implied-contract exception. Because THS employment is by nature temporary, there is little in the policies or business practices of THS employers that would likely be held by the courts to imply a contractual right to ongoing employment. Nor is there any precedent for finding client firms in violation of implied contracts for terminating workers on assignment through a THS firm (Lenz 1997). Hence, employers in states that have adopted the implied-

<sup>8</sup> The popular press also called attention to these legal developments. For example, a 1985 *Business Week* cover story entitled “Beyond Unions: A Revolution in Employee Rights Is in the Making” warned that “the time is coming when nonunion employees will no longer serve entirely at the employer’s will—the so-called employment-at-will doctrine that has prevailed in the United States since the late 1800s. Slowly but inexorably, judicial and legislative law is recognizing that even nonunion employees have an implicit employment contract that is enforceable in the courts” (Hoerr et al. 1985, p. 73).

<sup>9</sup> *Walker v. Northern San Diego County Hospital District* (135 Cal. App. 3d 896, 1982).

contract exception might be expected to face greater incentive to “out-source” employment to THS firms.<sup>10</sup> I discuss this point in more detail below.

### C. Other Exceptions to Employment at Will

In addition to the implied contract exception, many state courts have recognized two other exceptions to the at-will doctrine. The public policy exception, currently recognized by 41 states, bars employers from terminating employees for reasons that would contravene a statutory public policy. Essentially, this doctrine makes it illegal to retaliate against employees for upholding the law or exercising their statutory rights, for example, by attending jury duty, whistle-blowing, or refusing to commit a fraudulent act. A second less-widely recognized exception, the implied covenant of good faith and fair dealing, bars employers from terminating employees to deprive them of earned benefits, such as collecting an end-of-year sales bonus or a drawing a pension.<sup>11</sup>

While in theory the public policy and good faith doctrines may have consequences for employer conduct (cf. Dertouzos and Karoly 1992; Verkerke 1995; Morriss 1996; Olson 1997; Miles 2000; Autor et al. 2001), they are less likely to be relevant to outsourcing in general and THS employment in particular. The reason is that violations of these doctrines are actionable regardless of the identity of the employer (whether conventional firm or THS). Additionally, federal courts have ruled that staffing arrangements—which include temporary help—cannot be used to shield companies from civil-rights compliance. Hence, there is little reason to believe that the public policy and good faith exceptions confer a distinct legal advantage to THS firms.<sup>12</sup>

<sup>10</sup> Managers of manufacturing plants interviewed by Ballantine and Ferguson (1999, p. 5) explicitly mention using temporary workers to avoid legal risks. Quoting one interviewee, “We have temporaries here that have been here over a year. . . . We’ve also had people who have not worked out. We’ve had sexual harassment. We’ve had racial issues. We’ve had some drug issues and man, you get rid of those people fast. You don’t have to worry about anything legal. You just end the assignment.”

<sup>11</sup> In a handful of states, the public policy exception is construed more broadly to protect any action encouraged by public policy. The good faith exception is also read more broadly in several states to bar all terminations that are in “bad faith.”

<sup>12</sup> The civil rights case of *Amarnare v. Merrill Lynch* (611 F. Supp. 344 S.D. N.Y. 1984, aff’d, 770 F.2d 157 2d Cir. 1985) established the “no shielding” precedent. While the common law exceptions to employment at will are distinct from civil rights laws, the Amarnare precedent is likely to apply. Accordingly, a client firm could be held liable for instigating the termination of a THS worker in violation of the public policy or good faith doctrines.

## II. A Model of the Impact of Firing Costs on Employment Outsourcing

Why don't firms outsource all of their workers to circumvent firing costs? The hypothesis explored here is that by outsourcing employment, firms forgo productive specific human capital investments (in the sense of Becker 1964) that directly hired workers would otherwise undertake. Since specific capital is only valuable at the current job, workers facing briefer expected tenure make smaller specific capital investments. Recognizing this, firms may optimally precommit to longer tenure by hiring workers directly—particularly for occupations where specific capital is highly productive—even if THS arrangements offer lower firing costs.

Anecdotal evidence suggests that specific capital is indeed relevant to firms' outsourcing decisions. For example, in a study of the productivity consequences of temporary help outsourcing, Kahn (2000, pp. 242–43) writes, "In their decisions about the level of temp use, managers were extremely aware of the kinds of jobs where temps were useful and the kinds of jobs where this was not the case. For instance, one manager noted, 'Temps can describe the products we sell and take orders, but we would never hire a temp to handle customers unsatisfied with the service.' Managers also knew that when company-specific knowledge and experience were needed for the job, temps were inappropriate. . . . When only a modest amount of firm-specific experience was necessary, companies' policies made sure that the temps were well versed in the institutional knowledge and firms' computer systems by using the same temps repeatedly."

To study the impact of outsourcing on specific capital investment more formally, consider the following two-period model of employment where the first period consists of hiring and specific capital investment and the second period consists of production. There is a large number of identical, risk-neutral workers who live for two periods and a large number of firms. In period 1, workers and firms form matches and workers sink firm-specific skills investments  $s \in [0, \bar{s}]$  at cost  $c(s)$ , where  $c(\cdot)$  is a convex, strictly increasing, and continuously differentiable function with  $c(0) = 0$  and  $c'(0) = 0$ . Production and wages during this period are normalized to zero. At the close of the first period, the worker-firm pair receives a mean zero match-specific productivity shock,  $\eta$ , which can be thought of as realized match quality. For simplicity, I assume  $\eta$  has a uniform distribution,  $\eta \sim U[-z, z]$ .

If the worker-firm pair remains intact during the second period, the worker produces output of  $Y = \gamma \times s + \eta$ , where  $\gamma \geq 0$  is the productivity of specific capital investments at the job. If instead the pair splits, the worker receives an outside wage of zero. Additionally, if the worker was hired directly, the firm must pay a firing cost of  $\phi > 0$  to terminate

the position. If the firm hired the worker through THS, however, it pays no firing cost ( $\phi = 0$ ).

Since  $\gamma \times s$  is the return to firm-specific capital and  $\eta$  is a match-specific shock, neither is competitively priced, and their division will be determined by bargaining. I assume that wages are determined at the start of the second period by a Nash bargain, where the worker's bargaining power is given by the parameter  $\beta \in (0, 1)$ . If the worker-firm pair is unable to reach a bargain, the worker receives his outside wage of zero and the firm receives  $-\phi$ . Nash bargaining and risk neutrality imply that, if agreed, the worker's second period wage is:

$$w = \beta(\gamma \times s + \eta + \phi). \quad (1)$$

Three things about this setup deserve comment. First, it is important to stress that  $\phi$  represents a deadweight loss or a payment to an outside party such as a law firm and, hence, is not subject to Coasean compensation.<sup>13</sup> Second, the sole difference between direct hires and THS workers is that firms do not pay  $\phi$  to terminate THS workers. While in reality THS arrangements entail other transaction costs, including a sizable wage markup of 40%–50% (Autor, Levy, and Murnane 1999), I abstract from these details to emphasize that THS does not dominate direct hiring even absent transactions costs. Third, I assume that specific capital investments require observable but nonverifiable worker effort and commitment and are therefore not (fully) contractible.<sup>14</sup> Hence, as in Hashimoto (1981), Hart and Moore (1990), and Prendergast (1992, 1993), firms foster skill investment by rewarding realized productivity rather than by sharing in up-front investment costs. As is well known, if workers and firms can costlessly contract to share the costs and returns to specific skill investments, these investments will be made optimally. In this case, the trade-off expositied by the model would not be relevant. However, a growing theoretical and empirical literature demonstrates that because worker productivity is typically imperfectly observed by potential employers, human capital investments are likely to deviate significantly from the optimal case studied by Becker 1964 (cf. Acemoglu and Pischke 1999; Autor 2001). Hence, I consider the model germane to employer behavior.

#### A. The Impact of Firing Costs on Specific Skill Investments

Given the Nash bargain in equation (1), the worker-firm pair will only agree on a wage bargain if there is a positive surplus from continuing the relationship:

$$Y \geq -\phi. \quad (2)$$

<sup>13</sup> Any firing cost that is subject to Coasean compensation would also be present in the wage bargain but would not appear in  $\phi$ .

<sup>14</sup> In other words, the employer is able to observe the worker's specific capital investment, but a court would not.

Satisfaction of equation (2) further implies that  $w \geq 0$  and  $Y - w \geq -\phi$ ; a bargain is only feasible if the worker receives a nonnegative wage and the firm receives a continuation benefit at least equal to its firing cost.

Given equations (1) and (2), workers choose specific capital investment to maximize expected utility, which is the difference between expected earnings and the cost of specific capital investment:

$$\max_s E(U) = E(w|w \geq 0) \times P(w \geq 0) - c(s). \quad (3)$$

Using the uniform density to calculate expectations for  $\eta$ , the worker's first-order condition for specific capital investment is:

$$c'(s^*) = \frac{\beta\gamma(z + \gamma \times s^* + \phi)}{2z}. \quad (4)$$

This equation will have an interior solution at  $0 < s^* < \bar{s}$  provided that  $\gamma > 0$  and the training cost function is sufficiently convex.<sup>15</sup> As is visible from equation (4), the worker's skill investment is increasing in both the productivity of specific capital,  $\gamma$ , and in the worker's bargaining power. Critically, for purposes of the model, skill investment also depends positively on the firing cost. Because firing costs reduce the odds of termination in the second period, workers make larger specific skill investments when  $\phi$  is greater.<sup>16</sup>

#### B. Optimal Firing Costs versus Mandated Firing Costs

Now, consider the firm's trade-off between minimizing firing costs and maximizing specific capital investment. Expected profitability as a function of  $\phi$  is

$$E[\pi(\phi)] = \frac{(1 - \beta)[z + \gamma \times s(\phi) + \phi]^2}{4z} - \phi, \quad (5)$$

where I have written  $s(\phi)$  as an explicit function of  $\phi$  to underscore the dependence of specific skill investment on the firing cost. Observe that

<sup>15</sup> For simplicity, I also assume that  $\gamma \times s + \phi \leq z$ , which ensures that the probability bounds of the uniform distribution are not violated in eq. (4) and elsewhere. This assumption can be relaxed at no substantive cost by rewriting the expectation functions with minimums and maximums at  $-z$  and  $+z$ , respectively.

<sup>16</sup> Note that with a sufficiently skewed density function for  $\eta$ , it is possible to obtain the opposite result—that greater ex ante odds of termination increase worker skill investments. For example, if the probability mass of  $\eta$  were primarily concentrated at a threshold value, workers might invest heavily in specific capital to overcome this threshold. Substantively, because retaining a job using specific capital has a rent attached, added uncertainty could induce workers to make larger precautionary specific skill investments. Because of the unusual assumptions required on  $\eta$ , I consider this case remote.

$\phi$  enters both the credit and debit side of equation (5). Although  $\phi$  raises the cost of terminating workers, it also raises the expected profitability of those workers who are retained by increasing their incentives to make specific skill investments. This equation indicates that, independent of court mandates, firms may find it optimal to adopt positive firing costs  $\phi^*(\gamma) > 0$ , particularly for occupations where  $\gamma$  is large. Logically, the gain to firing costs is greater where specific capital investments are more productive ( $\gamma$  large):

$$\frac{\partial^2 \pi}{\partial \gamma \partial \phi} \geq 0. \quad (6)$$

How will firms respond when courts impose firing costs  $\tilde{\phi}$ ? Clearly, if optimal firing costs exceed mandated firing costs ( $\phi^*(\gamma) \geq \tilde{\phi}$ ), then  $\phi$  is nonbinding. But if mandated firing costs exceed optimal firing costs ( $\tilde{\phi} > \phi^*(\gamma)$ ), a subset of firms will find it more profitable to outsource despite the forgone specific capital investment. The likelihood that a firm will choose to outsource a given occupation depends directly on the magnitude of  $\phi^*(\gamma)$ . For occupations where specific capital is quite productive ( $\gamma$  large), the changing legal regime is unlikely to induce outsourcing because firms will have already written contracts more restrictive than  $\tilde{\phi}$ , and outsourcing these jobs may discourage substantial productive investment. Conversely, for occupations where specific capital is of minimal import, any increase in firing costs may be sufficient to yield employment outsourcing. Hence, the model suggests that firms will primarily respond to court-mandated firing costs by outsourcing those occupations that require the least specific capital.<sup>17</sup>

### C. Which Occupations Do Firms Outsource?

Do firms outsource low specific capital occupations to temporary help firms? Workers supplied by THS firms work overwhelmingly in occupations that rely on general, interchangeable skills. For example, low-skilled blue collar and administrative support occupations make up 63% of temporary help employment versus 30% of overall employment.<sup>18</sup> And even among white-collar occupations, THS workers are predominantly found in technical, computer, and medical occupations (such as nursing),

<sup>17</sup> If firing costs are also increasing in  $\gamma$ , then the relative profitability of outsourcing high versus low  $\gamma$  workers will depend on whether the marginal profitability of specific capital investment rises more or less quickly than the marginal firing cost. Since in theory the implied contract exception allows plaintiffs to sue for contractual economic losses (which could include the lost value of specific capital investment), it is plausible that  $\phi$  will depend positively on  $\gamma$ .

<sup>18</sup> Figures are from Cohany (1998), table 6, for operators, fabricators and laborers and administrative support, including clerical occupations.

where again skills are quite general (U.S. Department of Labor 1996, table 2).

To gauge the relevance of this relationship more rigorously, I combine data on the THS share of employment by detailed occupation during 1995–2001 with information on the prevalence of on-the-job training in each occupation (excluding THS).<sup>19</sup> Using these data, I explore whether THS penetration is greater in occupations that receive comparatively little workplace skills training. Specifically, I estimate the equation:

$$\text{THSshare}_j = \alpha + \beta_1 \times \text{Trained}_j + \beta_2 \text{Tenure}_j + \varepsilon_j, \quad (7)$$

where ( $j$ ) indexes 485 detailed (three-digit) occupations, THSshare is the average share of employment in the occupation supplied by THS firms during 1995–2001, and Trained is the share of (non-THS) workers in the occupation who report receiving skills training at their current jobs. Additionally, I control for mean job tenure in each occupation since omission of this variable could plausibly induce a spurious negative correlation between the share of workers trained at their jobs and the share of workers supplied by THS.

Estimates of equation (7), found in table 2, demonstrate that occupational training levels are a statistically and economically significant determinant of occupational THS penetration. A one-standard-deviation (SD) increase in the share of workers in an occupation receiving training at their jobs is associated with a 25% reduction in the mean occupational THS share. As would be expected, THS employment is also substantially lower in occupations with high average tenure. However, inclusion of the tenure variable only moderately reduces the estimated negative relationship between occupational skills training and THS penetration.

Additional estimates in table 2 replace the aggregate skills training variable with its subcomponents: school-based, formal employer-based, informal on-the-job, and other training. The negative relationship between training and THS penetration is reasonably pervasive across training ven-

<sup>19</sup> The THS occupational penetration measure is calculated from the combined CPS Contingent Worker Supplements for February 1995, 1997, 1999, and 2001 as the fraction of all currently employed workers in an occupation who are paid by a THS agency. Estimates are weighted by the overall fraction of national employment in each occupation in each year averaged over the four CPS Contingent Worker Supplements. Average tenure and training in each occupation are calculated from the January 1991 CPS Job Training Supplement for currently employed workers and are averaged to the occupation level using supplementary survey weights provided by the Bureau of Labor Statistics. All training measures refer to training obtained to improve skills at present job. The 1991 survey provides the most recent year of job training data available from the CPS.

**Table 2**  
**The Relationships among Occupational THS Penetration, Job Skills Training, and Employee Tenure in Detailed (Three-Digit) Occupations, 1995–2001**

	Means (SD)	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Share of workers trained at current job	.42 (.21)	–1.21 (.30)		–.93 (.32)				
Average worker tenure (years)	7.14 (2.58)		–.09 (.02)	–.06 (.03)	–.06 (.03)	–.08 (.03)	–.09 (.02)	–.05 (.02)
Share receiving in-school training	.16 (.12)				–1.46 (.49)			
Share receiving formal company training	.14 (.14)					–.70 (.54)		
Share receiving on-the-job training	.16 (.07)						.63 (.91)	
Share receiving other training	.08 (.07)							–4.88 (.88)
Intercept	.93 (1.39)	1.44 (.14)	1.56 (.18)	1.75 (.19)	1.57 (.18)	1.61 (.19)	1.49 (.21)	1.66 (.18)
$R^2$		.034	.028	.045	.046	.031	.029	.086

NOTE.—THS = temporary help services. Dependent variable:  $100 \times$  share of occupational employment provided by THS;  $n = 485$  detailed (three-digit) occupations. Ordinary least squares estimates given, and SEs are in parentheses. Tenure and training at current job are calculated from the January 1991 Current Population Survey Job Training Supplement for currently employed (non-THS) workers averaged to the occupation level using supplementary survey weights provided by the Bureau of Labor Statistics. All training measures refer to training obtained to improve skills at present job. The dependent variable is calculated from the combined CPS Contingent Worker Supplements for February 1995, 1997, 1999, and 2001. Estimates are weighted by the overall fraction of national employment in each occupation in each year averaged over the four CPS Contingent Worker Supplements.

ues. Apparently, firms do not typically outsource jobs in which skill investments are large.<sup>20</sup>

To summarize, in a labor market with imperfectly verifiable skills investments, firms may find it optimal to adopt positive firing costs to encourage workers to invest in specific human capital. Courts' imposition of mandated firing costs causes firms to outsource those jobs for which the mandated costs far exceed the firm's optimum. The jobs most likely

<sup>20</sup> Informal on-the-job training has no relationship with THS penetration. One reason may be that this variable measures a poorly defined construct. The strongest relationship found is for "other" types of training, which is unfortunately difficult to interpret. Recent work by Varejão and Portugal (2001) also confirms these relationships. Using data from Portugal, where firing costs are among the highest in the OECD (OECD 1999), Varejão and Portugal show that firms that invest relatively heavily in worker skill training are substantially less likely to hire workers on temporary contracts and yet are far more likely to convert workers hired on temporary contract to permanent status.

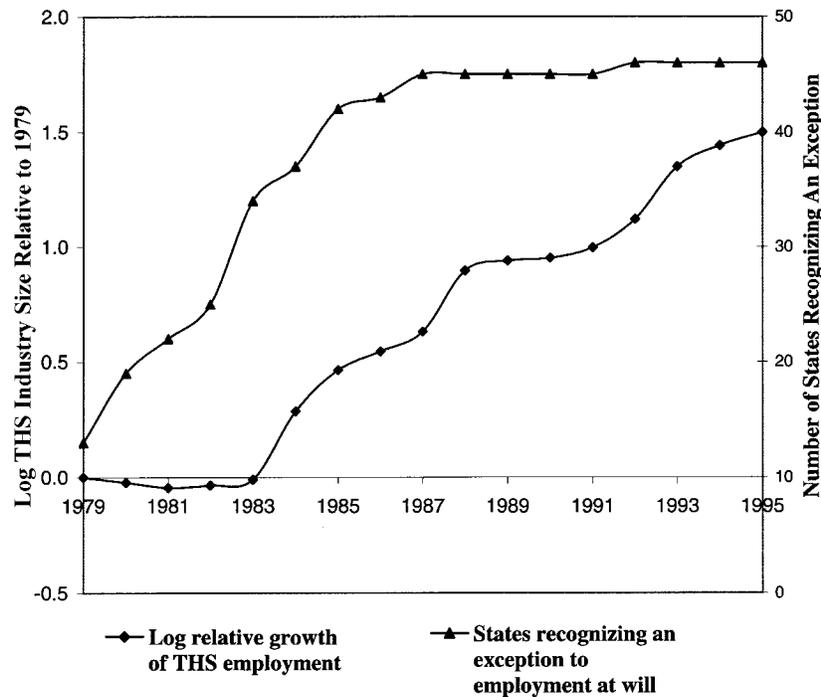

FIG. 2.—Log state temporary help supply industry growth, 1979–95, and number of states recognizing an exception to the employment-at-will doctrine.

to meet this criterion are those that rely heavily on general rather than firm-specific skills—which is a fair description of the occupations supplied by the THS industry. It therefore appears plausible that state courts' adoption of the implied contract exception may increase the demand for THS outsourcing.

### III. Empirical Framework and Data

#### A. Empirical Framework

Figure 2 presents the time series of U.S. states recognizing common law exceptions to employment at will between 1979 and 1995 alongside a plot of the unweighted average log size of THS employment in each state relative to 1979 after adjusting for state employment growth. The figure reveals a striking similarity in the movements of the two series, particularly after 1983. Of course, this relationship may not be causal. By exploiting the fact that the common law exceptions are adopted in different states and years, I assess their causal impact by contrasting THS employment growth in adopting and nonadopting states. Specifically, I es-

estimate differences-in-difference (or, more generally, fixed-effects) models of the form:

$$\begin{aligned} \ln(\text{THS}_{jt}) = & \alpha + \delta(\text{Common Law Exceptions}_{jt}) \\ & + \lambda(\ln \text{Nonfarm Emp}_{jt}) \\ & + \zeta(\text{Lab Force Demographics}_{jt}) \\ & + \mu_j + \tau_t + \varepsilon_{jt}, \end{aligned} \quad (8)$$

where the dependent variable is log temporary help employment in state ( $j$ ) and year ( $t$ ). In addition to dummies for adoption of common law exceptions, all estimates include a vector of state dummies,  $\mu_j$ , that control for mean differences in THS employment across states, and year dummies  $\tau_t$ , that control for THS growth common to all states. Some models also control for state nonfarm employment, labor force demographics, linear and quadratic state time trends, and region-by-year dummy variables. Because recent analyses demonstrate that pervasive serial correlation in state level difference-in-difference models may produce severely downward-biased standard errors (SE; Bertrand, Duflo, and Mullainathan 2001; Donald and Lang 2001), I use Huber-White SEs clustered at the state level throughout. These SEs are robust to arbitrary forms of error correlation within a state.

In applying the difference-in-difference framework to the data, it is important to consider carefully the “experiment” created by these court decisions. In the ideal case, the court decisions would be independent, random events that varied in timing and had no spillover effects to non-adopting states. If so, equation (8), if correctly specified, will provide an unbiased estimate of the average “treatment” effect,  $\delta$ .

The present analysis differs from this ideal case. The court rulings should not be viewed as independent events since 79 exceptions were recognized in 1979–95 as opposed to 20 in the preceding 2 decades. Because a movement to revise the at-will doctrine was visibly under way, firms may have responded preemptively, potentially by increasing demand for temporary help. Additionally, if the common law exceptions led to rapid growth of THS in affected states, this is likely to have contributed to the maturation and diffusion of an industry that, historically, was small and unsophisticated (Moore 1965). The differences-in-differences framework will fail to capture these effects if present, thereby potentially understating the total contribution of common law exceptions to the growth of THS.

Alongside these shortcomings, the common law exceptions have two virtues. First, the law changes are discrete. Second, because a court’s issuance of a new precedent is an idiosyncratic function of its docket and the disposition of its justices, the timing of a change to the common law

is likely to be in part unanticipated. Hence, even partly unanticipated law changes may generate discontinuous impacts on THS employment. The empirical approach will identify the extent of these discontinuous impacts.<sup>21</sup>

### B. Data Sources

To create a time series of state level THS and other business services industry employment, I use data from the Census Bureau's County Business Patterns (CBP) files for the years 1979–95. These data, collected annually from a theoretically complete universe of U.S. employers, provide a count of the total number of workers on THS payrolls during the month of March in each state and year. The CBP data do not distinguish between temporary and permanent employees of THS establishments, and hence line staff are included in these counts, although their employment share is likely to be small. The 1987 revision to the Standard Industrial Classification System (SIC) expanded the Temporary Help Supply Services industry (7362) to a slightly broader aggregate, Personnel Supply Services (7363). To the degree that this expansion is proportional across states, it will be absorbed by year effects.

As control variables for the THS employment equations, I use state-level nonfarm employment counts drawn from the Bureau of Labor Statistics State and Area Employment Statistics. I use the Outgoing Rotation Group (ORG) files of the Current Population Survey (CPS) for 1979–95 to create demographic controls for summary characteristics of the labor force in each state and year, including education, gender, age, marital status, and industry employment composition in one-digit CIC industries. For estimates of state-level union penetration, I use data from Hirsch, Macpherson, and Vroman (2001).

To characterize the state-by-year time series of exceptions to employment at will, I rely on Morriss (1995), who characterizes the relevant case law to 1989. For subsequent years, I combine information from Postic (1994) and the Bureau of National Affairs (1997). The cases cited for each exception are found in appendix A, table A1. The reader should be aware that characterizing the status of the common law is an inexact science, so in order to mitigate concerns about subjectivity, all of the results presented below were also estimated using the characterization developed by Dertouzos and Karoly (1992). The findings are neither qualitatively nor (sub-

<sup>21</sup> In their study of the impact of the decline of employment at will on state (non-THS) employment levels, Dertouzos and Karoly (1992) use a number of measures of states' legal and political climates as instrumental variables for the adoption of common law exceptions. While these factors may influence the probability of an adoption, the assumption that they are otherwise orthogonal to labor market conditions is suspect. Autor et al. (2001) demonstrate the substantial biases introduced by this instrumental variables approach.

**Table 3**  
**The Estimated Impact of Common Law Exceptions to Employment at Will on THS Employment, 1979–95**

Exceptions Recognized	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)

NOTE.—THS = temporary help services. Dependent variable: log state THS employment;  $n = 850$ . Ordinary least squares estimates given. Huber-White robust SEs in parentheses allow for arbitrary correlation of residuals within each state. For state common law information, see table A1.

stantially) quantitatively affected by the use of this alternative characterization.

Because the THS employment data are assembled from complete establishment counts and, hence, do not contain systematically heteroskedastic measurement error, estimates found in the body of the article are unweighted. Estimates that use state mean employment as weights, found in table B1, are closely comparable to unweighted estimates and are discussed briefly in the text.<sup>22</sup>

## IV. Empirical Results

### A. Initial Estimates

Summary data on THS employment by region and year are found in table 1, and initial estimates of equation (8) are found in table 3. Each column presents a regression of the log of state THS employment on state and time dummies, state linear time trends (in even-numbered columns), and indicator variables for the three common law exceptions, which are equal to one if an exception is present in a given state and year and zero otherwise. The first two columns contain the estimated impact of the implied contract exception on THS employment. The coefficient of 0.112 in column 1 indicates that after removing mean state THS levels and common year effects, THS employment grew by approximately 11.2 log points more in states adopting the implied contract exception than in nonadopting states. This impact is estimated imprecisely, however. The second column adds 50 state-specific time trends to the model, increasing the point estimate slightly to 13.6 log points and reducing the SE con-

<sup>22</sup> Since the empirical objective is to estimate the average “treatment” effect of common law exceptions on THS in percentage terms, there is also no a priori reason to place more weight on larger states.

siderably. An  $F$ -test of the hypothesis that the state trends are jointly zero is strongly rejected by the data, and hence I employ these linear trends in most specifications.

Comparable models estimated with the public policy and good faith exceptions are found in columns 3–6. Although both common law exceptions appear initially to contribute to the growth of THS, each point estimate becomes insignificantly negative once state trends are included. It appears that both the public policy and good faith exceptions were adopted in states where THS was already growing rapidly.

The last two columns of table 3 estimate the impact of the three exceptions simultaneously. The point estimate for each common law exception is only minimally affected by the inclusion of the others. The implied contract exception remains robust with a coefficient of 13.7 log points. The public policy and good faith exceptions are again insignificant once state trends are accounted for. Because these doctrines remain insignificant in the remainder of the analysis, they are not reported in subsequent tables, although they are always included in regression models.

#### B. Does the Specific Doctrine Matter?

The results in table 3 suggest that the implied contract doctrine is the only one of the three exceptions to employment at will to affect THS employment. It is possible, though, that it is not the implied contract doctrine in itself that matters but simply the fact that any exception to employment at will has been adopted (or the accumulation of multiple exceptions). To examine this issue, I begin with the specification from column 8 of table 3 (containing state time trends) and introduce in table 4 a variety of explanatory variables designed to control for the number or existence of legal exceptions in a state. The second column of table 4 shows that merely having any of the three legal exceptions to employment at will does not have an impact on state THS employment. The third column of table 4 reveals that the count of the number of legal exceptions does not correlate with a statistically significant increase in THS employment, nor do dummies indicating the individual presence of one, two, or three exceptions. Indeed, whether one controls for the existence of any legal exception (col. 5) or the count of the number of exceptions (col. 6), the implied contract dummy consistently has a positive and significant coefficient. It appears that the individual legal doctrine—as opposed to the existence of a single or number of exceptions—matters.

#### C. Controlling for Other Covariates

I next test the robustness of the results by controlling for a richer set of covariates, including state employment, quadratic state time trends, region-by-year effects, and labor-force demographics. Estimates are found

**Table 4**  
**The Estimated Impact of Common Law Exceptions to Employment at Will on THS Employment, 1979–95: Testing the Impact of the Number of Doctrines versus the Specific Doctrines**

Exceptions Recognized	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Implied contract doctrine	.137 (.062)				.126 (.067)	.216 (.116)	.151 (.085)
Public policy doctrine	-.023 (.058)				-.031 (.082)	.056 (.109)	.007 (.057)
Good faith doctrine	-.079 (.093)				-.084 (.090)		-.088 (.145)
Any doctrine		.071 (.065)			.022 (.091)		
Count of doctrines			.034 (.032)			-.079 (.093)	
One doctrine				.075 (.068)			
Two doctrines				.057 (.072)			-.055 (.092)
Three doctrines				.153 (.126)			.029 (.212)
$R^2$	.99	.99	.99	.99	.99	.99	.99

SOURCE.—For dependent variable, see County Business Patterns, various years.

NOTE.—THS = temporary help services. Dependent variable: log state THS employment;  $n = 850$ . Ordinary least squares estimates given. Huber-White robust SEs in parentheses allow for arbitrary correlation of residuals within each state. All models include state and year main effects and state specific linear time trends. For state common law information, see table A1.

in table 5. A first specification check addresses the concern that the states that adopted the implied contract were simply those undergoing faster employment growth. This would be true if courts in states with robust economies were particularly inclined to “liberalize” the employment regime. Column 1 of table 5 adds a control for the log of state nonfarm employment to the baseline specification, which obtains a coefficient of 1.5 conditional on trend. Consistent with Segal and Sullivan (1995), who report that THS employment is highly procyclical, the point estimate indicates that THS employment grew or contracted about 50% faster than overall employment within states on a year-to-year basis.<sup>23</sup> In columns 4–6, I add controls for quadratic state time trends and interactions between year dummies and indicators for each of the nine census regions that allow state THS employment to trend nonlinearly and also absorb region-specific shocks. The implied contract coefficient is largely insensitive to these additional controls.

To explore whether the estimates are driven by demographic changes

<sup>23</sup> One cannot, however, reject that the THS employment–overall employment elasticity is equal to 1.0 at the 5% level. Although the nonfarm employment measure also includes THS employment, THS is a small component (0.2%–2%) of the total, and subtracting it from the nonfarm employment measure has no discernable impact on the point estimates.

**Table 5**  
**The Estimated Impact of the Implied Contract Exception to Employment at Will on THS Employment, 1979–95, Controlling for State Demographics**

	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Implied contract exception	.148 (.057)	.132 (.063)	.174 (.056)	.141 (.068)	.134 (.077)	.145 (.056)	.141 (.068)

R <sup>2</sup>	.989	.990	.991	.993	.976	.989	.993

NOTE.—THS = temporary help services. Dependent variable: log state THS employment;  $n = 850$ . Ordinary least squares estimates given. Huber-White robust SEs in parentheses allow for arbitrary correlation of residuals within each state. All models include state and year dummies and dummy variables for public policy and good faith exceptions. Labor force demographics are calculated for state labor force (employed and unemployed) from Current Population Survey merged outgoing rotation groups (MORG) for 1979–95. Omitted reference group is unmarried white, male, high school dropouts ages 25–54.

in the labor force, I include in columns 5–7 detailed state demographic variables that measure the fraction of the labor force in the following groups: high school graduate, some college, and greater than college; female, married, and married and female; black and other race; and age 16–24 and 55 plus.<sup>24</sup> Consistent with the demographics composition of temporary help employment (Cohany 1998), there is a substantial correlation between the growth of THS and increases in the labor-force shares of high school graduates, some-college attendees, and women.<sup>25</sup> Subsequent columns add quadratic time trends and region-by-year dummies. In column 5, the base specification augmented with demographic controls, the estimated impact of the implied contract exception on THS employment is 13.3 log points. The final column yields a point estimate of 14.1 log points, which is stubbornly significant despite the inclusion of approximately 300 covariates.

Estimates of these models that use average state employment as weights are found in appendix table B1. These estimates confirm a significant effect of the implied contract exception on THS growth. In the base specification, column 2, the point estimate is 7.1 log points as compared with 14.8 log points for the unweighted estimate. When labor-force demographics, region-by-year dummies, and quadratic state time trends are included, the point estimate increases to 9.3 log points as compared with 14.1 log points for the unweighted estimate.

#### D. Estimates by Region and Time Period

Because the many court decisions altering the common law provide multiple “experiments,” one can usefully subdivide the data to provide a consistency check on the estimates. Two such tests are discussed here. The top panel of table 6 presents estimates of the baseline model using state-level data subdivided into three 4-year intervals over 1979–91.<sup>26</sup> To alleviate concern about the nonindependence of the outcome variable over short time spans, I estimate the models using observations at 1-, 2-, and 4-year frequencies. The point estimates present a highly consistent picture: the implied contract coefficient is positive in each case and generally in the range of 7–20 log points. Interestingly, the estimated impact of the implied contract exception does not appear smaller for later adopters, suggesting that anticipatory effects are not particularly important. The public policy and good faith exceptions (not tabulated) again present no

<sup>24</sup> The omitted group is white, male, high school dropouts ages 25–54. The labor force sample includes both employed and unemployed workers.

<sup>25</sup> Given the substantial overrepresentation of blacks in temporary help employment (22% of THS vs. 11% of non-THS employment in 1995 [Cohany 1998]), one surprising finding is the negative relationship between the share of a state’s labor force that is black and the level of state THS employment.

<sup>26</sup> No implied contract exceptions were adopted after 1989.

**Table 6**  
**The Estimated Impact of the Implied Contract Exception to Employment at Will on THS Employment by Time Period and Region**

	A. 4-Year Subperiods of 1979–91		
	1-Year Intervals ( <i>n</i> = 250)	2-Year Intervals ( <i>n</i> = 150)	4-Year Intervals ( <i>n</i> = 100)
1979–83	.122 (.088)	.073 (.092)	.034 (.152)
1983–87	.071 (.121)	.199 (.099)	.259 (.141)
1987–91	.145 (.110)	.089 (.047)	.187 (.106)
B. Nine Geographic Divisions, 1979–95			
	New England ( <i>n</i> = 102)	West North Central ( <i>n</i> = 119)	West South Central ( <i>n</i> = 68)
1979–95	.146 (.102)	.116 (.122)	.077 (.137)
	Middle Atlantic ( <i>n</i> = 51)	South Atlantic ( <i>n</i> = 136)	Mountain Division ( <i>n</i> = 136)
1979–95	.000 (.064)	.154 (.071)	.478 (.187)
	East North Central ( <i>n</i> = 85)	East South Central ( <i>n</i> = 68)	Pacific Division ( <i>n</i> = 85)
1979–95	.166 (.110)	.009 (.089)	.057 (.157)

NOTE.—THS = temporary help services. Dependent variable: log state THS employment. Ordinary least squares estimates given. Huber-White robust SEs in parentheses allow for arbitrary correlation of residuals within each state. Each coefficient is from a separate regression of log state THS employment on a dummy variable equal to one after adoption of an implied contract exception. All models include state and year dummies, a control for the log of state nonfarm unemployment, and dummy variables for public policy and good faith exceptions. The first column of panel A and all models in panel B also include controls for state linear time trends. Note that no implied contract exceptions were adopted after 1991.

clear pattern. In the lower panel of table 6, I provide estimates of the base specification for each of the nine geographic census regions. These estimates are reasonably stable across census regions: positive in eight of nine regions, and in the range of 6–17 log points in six of these.<sup>27</sup>

#### E. Inferring Causality via the Timing of Common Law Changes

The discrete specification above provides no sense of the dynamics of common law adoption and THS employment: how quickly employment

<sup>27</sup> In regressions not tabulated here, I find that there is never a significant cross-sectional relationship between either the log level or the share of employment in a state supplied by THS and the presence of an implied contract exception. Apparently, there are important unmeasured determinants of cross-state THS penetration, which are effectively purged by the fixed-effects model used for the primary analysis.

R <sup>2</sup>	.973	.989	.991	.993

NOTE.—THS = temporary help services. Dependent variable: log state THS employment;  $n = 850$ . Ordinary least squares estimates given. Huber-White robust SEs in parentheses allow for arbitrary correlation of residuals within each state. All models include state and year dummies, a control for log state nonfarm employment, and leads and lags of adoption of the public policy and good faith exceptions. Law change dummies  $t_{+2} - t_{-3}$  are equal to one in only 1 year each per adopting state. Implied Contract<sub>*t*-4 forward</sub> dummy is equal to one in every year beginning with the fourth year after adoption.

grows after an exception is adopted and whether this impact accelerates, stabilizes, or mean reverts. If temporary help employment growth leads to the adoption of exceptions rather than vice versa, the previous estimates would obscure this reverse causality. To explore these dynamics, table 7 provides estimates of a subset of the models in table 5, augmented with leads and lags of the implied contract exception. Specifically, I add indicator variables for 1 and 2 years before adoption, years 0–3 after adoption, and year 4 forward. Of these seven indicator variables, note that the first six are equal to one only in the relevant year, while the final variable is equal to one in each year, starting with the fourth year of adoption.

The first column of table 7 presents the base specification augmented with the leads and lags. The coefficients on the adoption leads are close to zero, showing little evidence of an anticipatory response within states about to adopt an exception.<sup>28</sup> In the year of adoption, temporary help employment increases substantially by 12 log points, after which this

<sup>28</sup> This finding should be distinguished from the hypothesis that employers in all states increased their demand for THS as an anticipatory response to common law changes. This latter phenomenon would not be detected by preadoption dummies unless employers foresaw individual court decisions in their own states.

increment fluctuates at between 8 and 17 log points over the subsequent 3 years; then it averages 10 log points in year 4 forward. Subsequent columns repeat these estimates, adding linear and quadratic time trends and region-by-year effects. The pattern of coefficients is comparable in each case, providing robust evidence that adoption of the implied contract exception led the growth of THS rather than vice versa. In the preferred specification that includes linear state trends (col. 2), the estimated impact is 19.6 log points at year 4. This pattern is depicted by figure 3.

In results not tabulated here, I have explored more complex dynamics by allowing the common law exceptions to take a linear or quadratic time slope and including additional years of indicator variables. The data reject these more complex specifications in favor of those found in table 7. I find no evidence of an accumulating impact on THS employment beyond 4 years, nor is there evidence of mean revision in the longer term. It thus appears that the extent of the dynamics of the THS demand response to adoption of the implied contract exception is resolved within 4 years. Note, however, that since THS expanded rapidly throughout this time, a constant impact of 13–20 log points (~ 14–22 percentage points) implies a growing absolute effect on THS employment.<sup>29</sup>

Two further observations on this pattern of results deserve mention. First, the quite rapid growth of THS employment after the adoption of an implied contract exception—on the order of 10% in the year of a ruling—may appear implausibly large. Note, however, that THS is an industry characterized by extremely high flows. For example, Segal and Sullivan (1997*b*) estimate that 60% of THS workers leave the industry within 1 calendar quarter. A substantial change in the scale of the industry therefore requires only that the exit rate decreases slightly (e.g., assignments lengthen) or that intake accelerates.

A second issue is whether, contrary to the estimates above, one should expect the “steady state” impact of a common law change on THS to be more substantial than the near-term impact. The stylized model in Section II suggests that the degree to which firms outsource employment in response to the legal environment is circumscribed by the “technology” of jobs ( $\gamma$  specifically), in particular how much outsourcing reduces productivity relative to termination costs. More generally, it seems likely that firms facing added legal risks will alter their occupational technology to make outsourcing less costly, perhaps by shifting the mix of human capital from specific toward general skills (e.g., using off-the-shelf instead of custom software) or learning to manage outsourced workers more effectively. Logically, the temporary help industry has striven to assist this

<sup>29</sup> Models that control for the fraction of neighboring states and the fraction of states in the same census region recognizing an implied contract exception show no evidence of geographically localized spillovers from the common law changes.

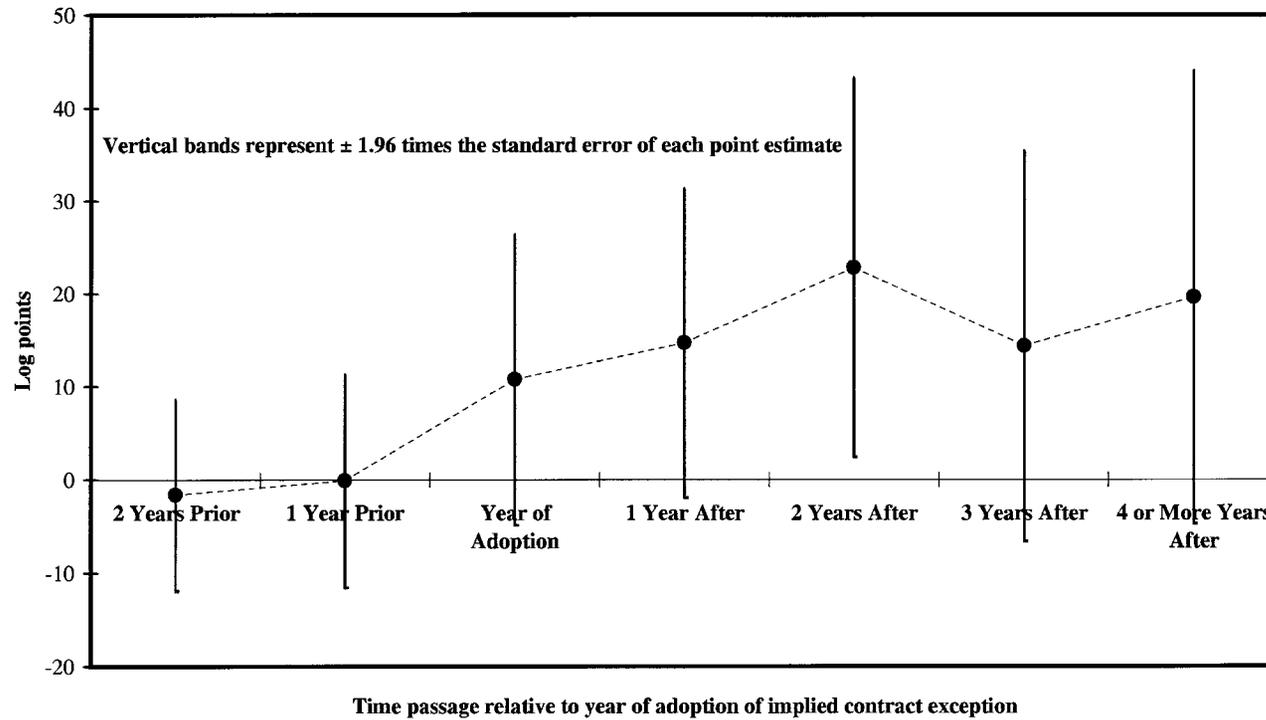

FIG. 3.—Estimated impact of implied contract exception on log state temporary help supply industry employment for years before, during, and after adoption, 1979–95.

effort by developing a sophisticated capacity for training and screening workers (Autor 2001). Unfortunately, the present empirical framework is unable to detect any richer interplay between the legal environment and the growth of outsourcing since these practices will diffuse slowly and potentially affect all states simultaneously.

#### F. Unionization and the Growth of Temporary Help Employment

A potentially complementary explanation for the recent growth of outsourcing in the United States is the changing role of labor unions. Unionized workers have traditionally received greater employment protections than those provided by the at-will doctrine, and it is therefore sensible to ask whether the recent decline of unionization has played a role in the erosion of employment at will and the growth of temporary help. Unions might affect the development of temporary help either indirectly, by influencing the adoption of unjust dismissal doctrines, or directly, by either retarding or contributing to employers' demand for THS workers.

To explore these possibilities, I first estimated probability models in a state-by-time panel to explore whether states where union penetration was growing or declining relatively faster were more likely to adopt common law exceptions. I found no evidence to support this notion, and these results are not tabulated.<sup>30</sup> I next estimated models of log THS employment comparable with those in table 5, which control for the percentage of the state workforce that is unionized. These estimates, found in table 8, provide surprisingly robust evidence that union penetration affects temporary help employment.

The initial column of table 8 presents a model of log state THS employment controlling only for state union penetration and state and year dummies. The union coefficient of 0.026 implies that for every percentage-point increase in unionization, THS employment grows by 2.6 log points. Inclusion of state linear time trends reduces this coefficient to 0.016, which remains highly significant. Subsequent columns add controls for the adoption of the implied contract exception, the log of state nonfarm employment, and a full set of trends, region-by-year effects, and labor-force demographics. Additionally, because of the concern that state unionization level might proxy for the presence of manufacturing, which is a substantial user of temporary help workers (Estavao and Lach 1999), column 2 adds controls for employment composition in 12 major industries. The union

<sup>30</sup> Miles (2000) also reports that state unionization levels have no impact on the expected time duration until a state adopts a common law exception.

**Table 8**  
**Union Penetration, the Implied Contract Exception to Employment at Will and State THS Employment, 1979–95**

	(1)	(2)	(3)	(4)	(5)	(6)

State × time <sup>2</sup> trends	No	No	No	No	No	Yes
Region by year dummies	No	No	No	No	No	Yes
Labor force demographics	No	No	No	No	No	Yes
R <sup>2</sup>	.969	.988	.987	.989	.989	.993

NOTE.—THS = temporary help services;  $n = 850$ . Ordinary least squares estimates given. Huber-White robust SEs in parentheses allow for arbitrary correlation of residuals within each state. State fraction unionized measures are from Hirsch et al. (2001). All models also include state and year dummies and dummies for public policy and good faith exceptions. Labor force demographics (col. 6) are as in table 5. Models in cols. 2, 5, and 6 include controls for the fraction of the state labor force in each of 12 major industries estimated from the Current Population Survey Merged Outgoing Rotation Groups (MORG) files.

impact on THS employment remains significantly positive and in the range of 1.5 log points.<sup>31</sup>

In interpreting the THS-unionization relationship, two points should be kept in mind. First, union penetration fell substantially over this time period, from 22% to 14% in the data, and hence unionization does not contribute to an explanation for the recent growth of THS. Instead, the estimates are best read as indicating that temporary help grew relatively faster in states where unions declined more slowly. Second, unlike the case of the implied contract doctrine, the unionization estimates do not have a clear causal interpretation since union penetration cannot be viewed as exogenous. The relationship is nevertheless suggestive and provides an empirical underpinning for the visible enmity between THS employers and U.S. labor unions (cf. Carré, duRivage, and Tilly 1994; Lips 1998). One interpretation of this finding is that employers in highly unionized states use temporary help to avoid union constraints on wages or man-

<sup>31</sup> An interaction between the level of unionization and a dummy for the implied contract exception was small and insignificant.

agement practices. An alternative and probably less viable reading is that high levels of THS employment contribute to workers' demands for union representation.

#### G. Impact of the Decline of Employment at Will on Other Business Services Employment

Although temporary help grew substantially faster than other forms of outsourced employment, non-THS business service employment (such as janitorial services and computer and data processing) also experienced rapid growth between 1979 and 1995, rising from 2.1% to 3.6% of employment (excluding THS). It is natural to ask whether the erosion of employment at will contributed to this phenomenon as well. To explore this question, I estimate log employment models as in table 8 for each of the business service industries. Before proceeding to these estimates, I note that the legal analysis above indicates that the adoption of unjust dismissal doctrines would not directly contribute to the growth of other business services since, unlike THS, these industries are not directly advantaged by these doctrines. Hence, these results may be viewed as a falsification test of the earlier findings.

Estimates in table 9 give little indication that the adoption of the implied contract doctrine contributed to the growth of other business service employment. Except for those subcomponents of business services that contain temporary help (table 9, rows 1 and 10), the estimates are primarily insignificant and do not have consistent signs. Results for the impacts of the public policy and good faith doctrines (not tabulated) and the unionization variable also present no consistent pattern.

### V. Conclusions

To summarize the primary findings, figure 4 depicts the time series of states adopting the implied contract exception alongside estimates of temporary help employment for 1979–95, both before and after conditioning on the adoption of the implied contract exception. A fourth line on this plot indicates the share of the growth of temporary help since 1973 explained by changes to the at-will doctrine. The estimates indicate that as of 1995, 306,000 additional workers were employed in temporary help on a daily basis as a result of the implied contract exception.

Extending this estimate forward and using the weighted and unweighted point estimates to form bounds, I find that 361,000–530,000 additional workers were employed in temporary help as of the year 2000 because of the implied contract exception.<sup>32</sup> As the lower line of figure 4 indicates,

<sup>32</sup> As of 1995, the most recent year for which state level estimates are available, 75.6% of THS employment was in states that had adopted an implied contract exception. Assuming this ratio continued to hold as of 2000, when national THS

SOURCE.—For business services employment, see County Business Patterns (various years).

NOTE.—SIC = standard industrial classification; THS = temporary help services. Dependent variable is log state employment in business services and its subsectors;  $n = 850$ . Ordinary least squares estimates given. Huber-White robust SEs in parentheses allow for arbitrary correlation of residuals within each state. Estimates include state and year dummies, state linear time trends, and dummies for public policy and good faith exceptions. State fraction unionized are from Hirsch et al. (2001). Business services employment counts are adjusted for compatibility between the 1977 and 1987 SIC standards.

the estimates explain as much 20% of the growth of temporary help services employment over the 23-year period from 1973 to 1995. Observe, however, that the explanatory power of the model actually falls in the recent period since temporary help has continued to expand rapidly since 1992, several years after the most recent implied contract exception was adopted. Hence, the present analysis provides a starting point for understanding the recent dramatic growth of THS specifically and outsourcing more generally but is not a complete account.

employment was equal to 3,887 thousand, the total employment estimated impact is  $3,887 \times 0.756/[i/(1+i)]$ , where  $i$  is equal to either 0.14 (weighted estimate) or 0.22 (unweighted estimate).

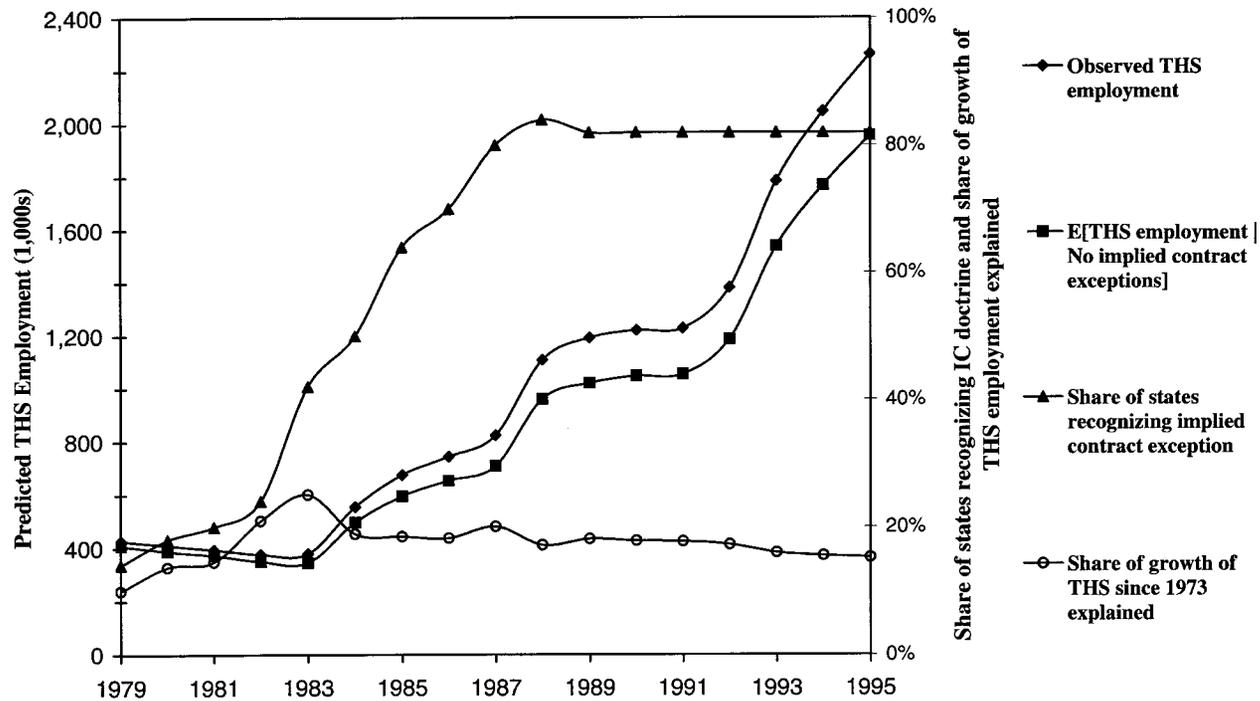

FIG. 4.—Predicted state temporary help supply industry employment, 1979–95, conditioning on adoption of implied contract exceptions

There is an irony to the findings of this research—namely, that labor-market interventions intended to protect or expand workers’ employment “rights” appear to have had unintended and potentially perverse consequences. Acemoglu and Angrist (2001) and DeLeire (2000) conclude that the Americans with Disabilities Act reduced the employment of the disabled, while Oyer and Schaefer (2000, 2002) present evidence that the Civil Rights Act of 1991 increased firms’ use of mass layoffs as a shield for the firing of black men and raised the earnings of experienced workers relative to the young. In a similar vein, the current research suggests that courts’ efforts to protect workers against unjust dismissal have fostered the growth of temporary help employment—nonpreferred jobs that offer less job security and lower pay than standard positions. Moreover, there is some evidence that labor unions, which have historically provided employment protection to their members, also induce employment outsourcing to temporary help.

It should be stressed, however, that the welfare impacts of the decline of employment at will are indeterminate based on the present evidence. While the current analysis explores one margin of response to the changing legal doctrines, it offers no evidence on the compensatory benefits that workers may have received by dint of these laws. Theory also suggests that some legal restrictions on private contracting can enhance efficiency (Aghion and Hermalin 1990; Levine 1991). Whether workers were in net harmed by these well-meaning judicial efforts—and if so, which groups of workers have borne the greatest burden—is a question open to research.

NOTE.—Blank entries in the table indicate that no exception was recognized in the relevant state and category.

## Appendix B

**Table B1**  
**The Estimated Impact of the Implied Contract Exception to Employment at Will on THS Employment, 1979–95, Weighted by State Employment Shares**

	(1)	(2)	(3)	(4)	(5)
Implied contract exception	.071 (.038)	.069 (.040)	.099 (.034)	.085 (.039)	.093 (.039)
Other covariates:					
State × time trends	Yes	Yes	Yes	Yes	Yes
State × time <sup>2</sup> trends	No	Yes	No	Yes	Yes
Region by year dummies	No	No	Yes	Yes	Yes
Labor force demographics	No	No	No	No	Yes
$R^2$	.991	.993	.994	.995	.995

NOTE.—THS = temporary help services. Dependent variable: log state THS employment;  $n = 850$ . Ordinary least squares estimates given. Huber-White robust SEs in parentheses allow for arbitrary correlation of residuals within each state. Estimates weighted by mean state share of national employment over 1979–95. All models include dummy variables for public policy and good faith common law exceptions, state and year dummies, and state linear time trends. Labor force demographics in col. 5 are as in table 5.

## EXECUTIVE SUMMARY

- Puerto Rico faces hard times. Structural problems, economic shocks and weak public finances have yielded a decade of stagnation, outmigration and debt. Financial markets once looked past these realities but have since cut off the Commonwealth from normal market access. A crisis looms.
- For its part, the administration has worked hard to stave off a financing crisis with important measures since 2013, including higher taxes, pension reforms and spending cuts. However, as much as these are needed, much remains to be done to build on this progress. Given the economic downdrafts, the coming years will be difficult. But it is within the power of this government, which has repeatedly demonstrated a willingness to act, to set the economy on a sustainable path.
- Puerto Rico has advantages it can parlay into market confidence and durable growth if decades-old policy failings are fully addressed. The debt cannot be made sustainable without growth, nor can growth occur in the face of structural obstacles and doubts about debt sustainability. The strategy here is an integrated package, indicative of the scope and order of magnitude of needed policies:
  - *Structural reforms.* Restoring growth requires restoring competitiveness. Key here is local and federal action to lower labor costs gradually and encourage employment (minimum wage, labor laws, and welfare reform), and to cut the very high cost of electricity and transportation (Jones Act). Local laws that raise input costs should be liberalized and obstacles to the ease of doing business removed. Public enterprise reform is also crucial.
  - *Fiscal reform and public debt.* Probably the most startling finding in this report will be that the true fiscal deficit is much larger than assumed. Even a major fiscal effort leaves residual financing gaps in coming years, which can be bridged by debt restructuring (a voluntary exchange of existing bonds for new ones with a longer/lower debt service profile). Public enterprises too face financial challenges and are in discussions with their creditors. Despite legal complexities, *all* discussions with creditors should be coordinated.
  - *Institutional credibility.* The legacy of weak budget execution and opaque data – our fiscal analysis entailed many iterations – must be overcome. Priorities include legislative approval of a multi-year fiscal adjustment plan, legislative rules on deficits, a fiscal oversight board, and more reliable and timely data.
- This is a daunting agenda politically, legally, and organizationally. It is also an urgent one: the government's cash balances can evaporate in the face of delays, reducing the room for maneuver and intensifying the crisis.

**ACKNOWLEDGEMENTS.** Without implicating anyone, we thank the many Commonwealth officials, business leaders and private economists – among the latter, Mohinder Bhatia, Vicente Feliciano, Jorge Freyre, Juan Lara, and Sergio Marxuach – who generously shared their insights and expertise. The report also draws on numerous studies on the structural challenges facing the Commonwealth. Rather than cite all these, we refer the reader to the analysis and references in the New York Federal Reserve’s excellent [Update on the Competitiveness of Puerto Rico’s Economy](#) (2014).

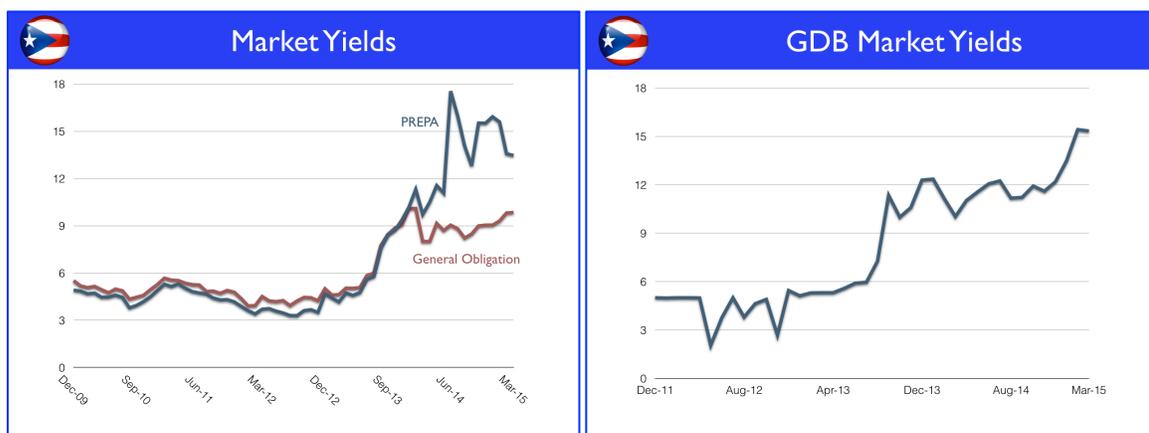

**DISCLAIMER.** This report was prepared at the request of legal counsel, and is for discussion purposes only. It is based on publicly available information, as well as reports and discussions with experts engaged by the Commonwealth of Puerto Rico (the “Commonwealth”), the Government Development Bank for Puerto Rico (“GDB”), and certain other government instrumentalities of the Commonwealth. The information contained in this report has not been reviewed by any auditors (independent or otherwise), nor have such auditors been consulted. The authors of this report have made no independent verification as to the accuracy or completeness of the information contained herein, and they assume no responsibility for independently verifying the information contained herein. Accordingly, they make no representation or warranty as to the accuracy, completeness, or reasonableness of the information herein, and this report, including any analysis or description of any possible recommended measures, is subject to reconsideration and modification at any time. ♦ The description of potential fiscal or structural measures set forth herein is not exhaustive, nor should it be viewed as an unqualified recommendation or endorsement of any specific measure, and that there may be compelling policy and other reasons not to adopt such recommendations. The authors acknowledge that any specific recommendation may be impractical or impossible to implement for a variety of reasons and that the authors do not possess all of the information that may be relevant to the consideration of any specific measure. Any statements contained in this report, whether forward-looking or historical, are not guarantees of future performance and involve certain risks, uncertainties, estimates and assumptions made in this report. The economic and financial condition of the Commonwealth and its instrumentalities is affected by various financial, social, economic, environmental, and political factors. These factors can be very complex, may vary from one fiscal year to the next, and are frequently the result of actions taken or not taken, not only by the Commonwealth and its agencies and instrumentalities, but also by entities such as the government of the United States. Because of the uncertainty and unpredictability of these factors, their impact cannot be included in assumptions in this report. Future events and actual results may differ materially from any estimates, projections or statements contained herein. ♦ Nothing in this report should be considered as an express or implied commitment to do or take, or to refrain from taking, any action by the Commonwealth, the GDB or any government instrumentality in the Commonwealth. Nothing in this report shall be considered a solicitation, recommendation or advice to any person to participate, pursue or support a particular course of action or transaction, to purchase or sell any security, or to make any investment decision. Nothing contained herein may be used or offered into evidence in any legal, administrative or other proceeding.

## I. THE CRISIS OF CONFIDENCE

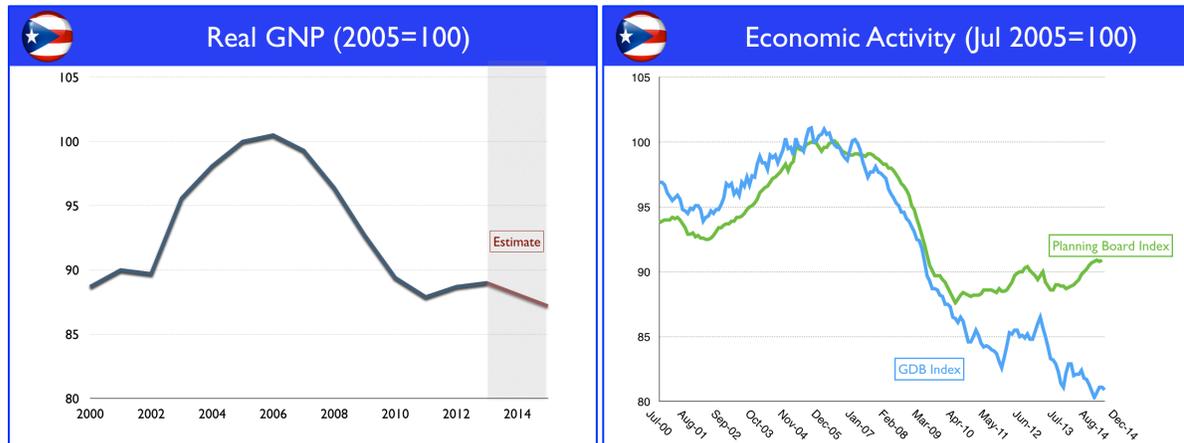

*The shut off from normal market access risks a more pronounced crisis than the slow-motion deterioration the island has endured since 2005. The loss of confidence stems from protracted economic stagnation and weak public finances, which feed each other.*

### 1. Market confidence in the sustainability of public debt has deteriorated markedly.

Starting in 2013, risk premia on general obligation bonds began moving up steadily, as did those on the obligations of public enterprises. The traditional base of municipal bond investors narrowed after ratings agencies downgraded Puerto Rico debt to below investment grade in early 2014, with new investors demanding higher risk premia, shorter maturities, and greater seniority. The mid-teen yields of the government's fiscal agent, the Government Development Bank (GDB), also confirm that the market sees a weak liquidity position and puts a high probability on the risk of default. As a result, the Commonwealth is now virtually shut off from normal market access.

2. **Sections II-III explore the main factors – economic stagnation and persistent fiscal deficits – behind the market's negative assessment of debt sustainability.** Few countries have been able to establish debt sustainability with low growth, which limits revenues and raises debt ratios. In Puerto Rico, growth has not just been low but output has actually been *contracting* for almost a decade now, which is remarkable for an economy suffering neither civil strife nor overt financial crisis. GNP data for the fiscal year ending June 2014 suggest that the economy shrank by about 1% in FY2014. More recent data are not available but our reading of the indicators is that the economy continues to contract at a rate of *at least* 1% per annum, likely more, in FY2015. As discussed in Section II, the drivers of economic decline have been years in the making: the problems are structural, not cyclical, and as such are not going away. Further, as discussed in Section III, fiscal deficits are much larger than assumed. The actions to date are insufficient, and fiscal deficits too are not going away. The economy is in a vicious circle where unsustainable public finances are feeding into uncertainty and low growth, which in turn is raising the fiscal deficit and the debt ratio.

3. **Section IV-VI explain the urgency in the current situation and the case for an alternative approach.** The cash flow position of the government is fast deteriorating. In Section IV, we estimate the fiscal financing gap that must be filled just on current trends (let alone on a deterioration of prospects). This is followed in Section V by a discussion of possible measures to rein in deficits in a manner that is least harmful to growth prospects – certainly less harmful than the alternative of an overt crisis – and the need for debt service relief until such time as the reform program can restore growth and the sustainability of public finances. Section VI subjects the analysis to some skeptical questions.

## II. ECONOMIC ORIGINS

*Both economic shocks and flawed policies have played a role in Puerto Rico's decline. After a decade of stagnation, negative growth is now mostly a supply side problem.*

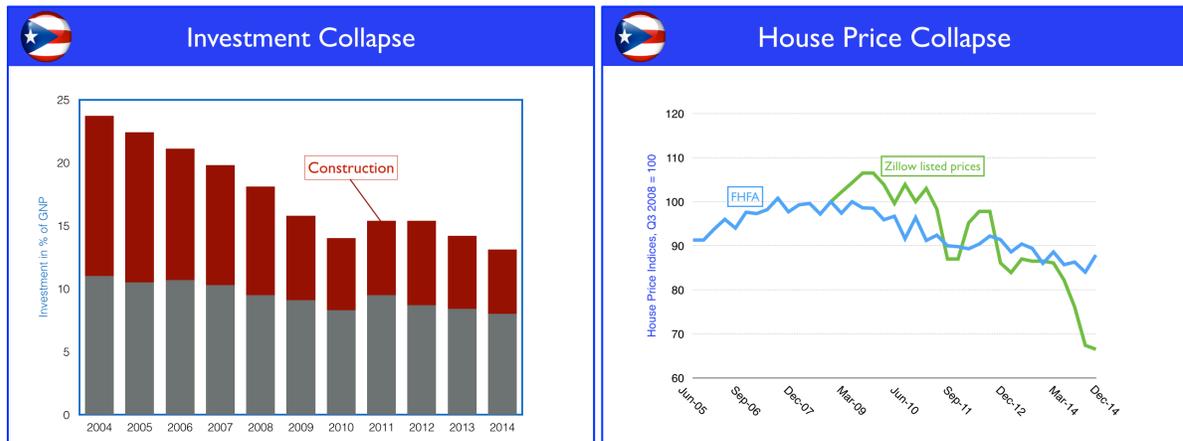

4. **The economic shocks have been numerous.** Because negative growth coincided with the final phase-out of IRS Section 936 provisions for mainland manufacturers on the island, it is customary to cite the loss of tax preferences as the original sin behind Puerto Rico's travails. The loss undoubtedly hollowed out the manufacturing base but was hardly the only blow. Many other forces, perhaps collectively more important, also bore down:

- *Investment/housing bust.* Investment fell by 10% points of GNP in the decade to FY2014, with construction accounting for three-quarters of the overall reduction in the investment ratio. Much of the damage came from the sharp fall in house prices<sup>1</sup>, which preceded the one on the mainland and may be larger than commonly cited indices suggest. Lower home prices reduced the net wealth of individuals and small

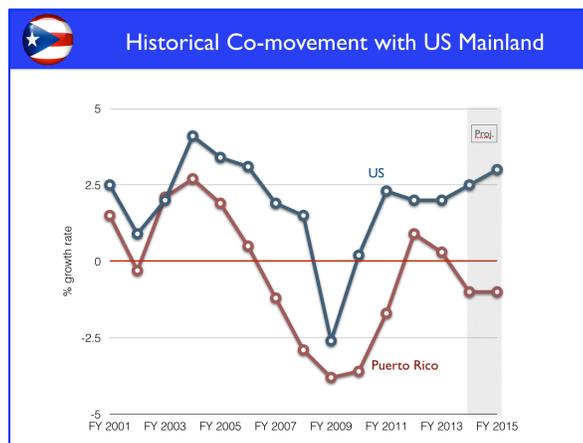

<sup>1</sup> The Federal Housing Finance Administration (FHFA) produces a "repeat sale" index that, by definition, excludes new home sales. But unsold *new* homes have been a big part of the housing boom-bust in Puerto Rico. The figure below on the right therefore also shows a broader index: Zillow's median list prices for new and existing homes. The 38% decline in the latter is large and indicative of on-going market pressures.

PUERTO RICO – A WAY FORWARD

firms, and thus their capacity to borrow. The resulting weakness in consumption and investment, in turn, fed back into housing weakness – another vicious cycle.

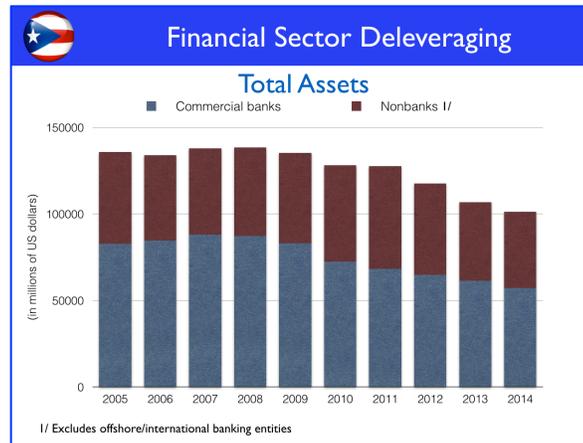

- Recession on the US mainland.* Until recently, economic activity in Puerto Rico tracked that on the US mainland, the island's largest trade partner and investor. As such, the downturn in US activity during 2007-09 had a significant negative effect. The subsequent recovery in US demand should have lifted key sectors such as manufacturing, which is overwhelmingly geared to the US. The fact that this has not happened suggests a structural problem with competitiveness.

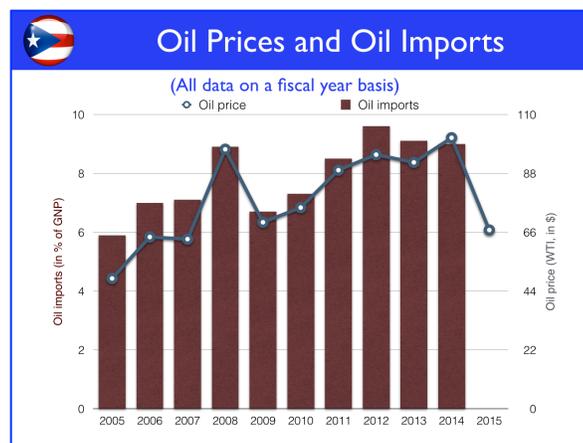

- Bank distress and credit crunch.* The fall in the economy and housing was amplified by the associated distress in the banking sector and vice versa. Commercial bank assets have fallen by 30% since 2005, as banks reduced their balance sheets in response to the hit to their capital from lower asset prices. The distress in the banking sector would have been worse were it not for the backstop provided by FDIC, which had to intervene several banks, and for initiatives such as TARP.

## PUERTO RICO – A WAY FORWARD

- *Oil prices.* The doubling in oil prices during 2005-12 was a major setback, given Puerto Rico's dependence on imported oil for virtually all of its power generation. The 3% of GNP increase in the oil bill represented an equivalent loss of income for Puerto Rico that could have supported the local economy.

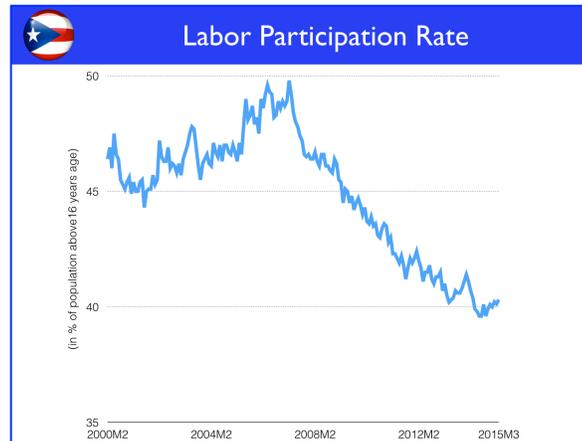

##### 5. **But even more significant forces on the supply side have been gnawing at growth:**

- *Employment and labor costs.* The single most telling statistic in Puerto Rico is that only 40% of the adult population – versus 63% on the US mainland – is employed or looking for work; the rest are economically idle or working in the grey economy. In an economy with an abundance of unskilled labor, the reasons boil down to two.
  - Employers are disinclined to hire workers because (a) the US federal minimum wage is very high relative to the local average (full-time employment at the minimum wage is equivalent to 77% of per capita income, versus 28% on the mainland) and a more binding constraint on employment (28% of hourly workers in Puerto Rico earn \$8.50 or less versus only 3% on the mainland); and (b) local regulations pertaining to overtime, paid vacation, and dismissal are costly and more onerous than on the US mainland.

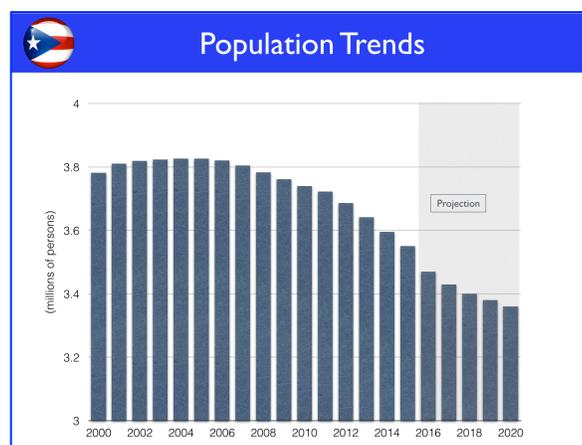

## PUERTO RICO – A WAY FORWARD

- Workers are disinclined to take up jobs because the welfare system provides generous benefits that often exceed what minimum wage employment yields; one estimate shows that a household of three eligible for food stamps, AFDC, Medicaid and utilities subsidies could receive \$1,743 per month – as compared to a minimum wage earner’s take-home earnings of \$1,159.

The result of all of the above is massive underutilization of labor, foregone output, and waning competitiveness.

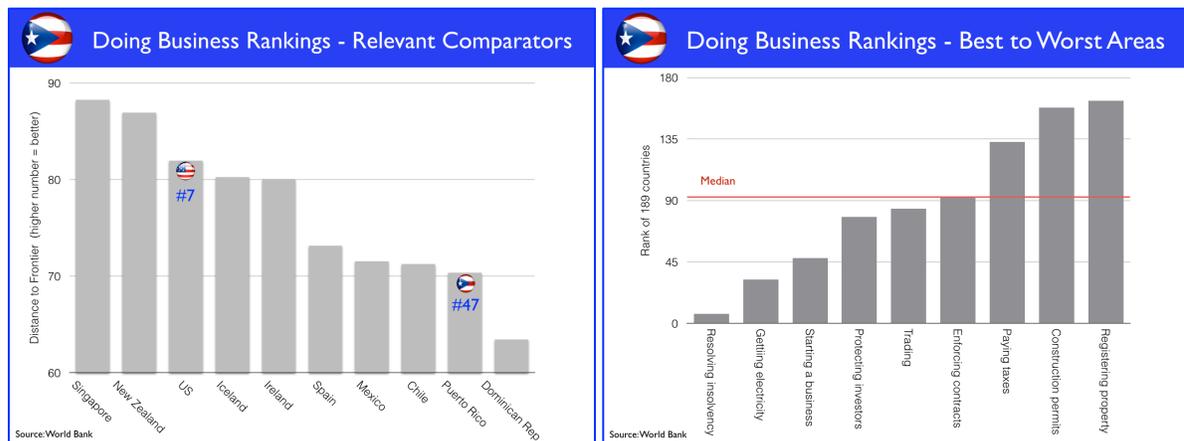

- **Outmigration and population loss.** Diminished job opportunities have also prompted a sharp rise in outmigration, greater even than that in the 1950s. As a result, after growing continuously for almost two centuries, Puerto Rico’s population declined for the first time in 2006, and has since shrunk from its peak to about 3.5 million in 2015. Even if there is no intensification in economic problems, which is a big if, the Planning Board projects that the population will continue to fall through 2020. The loss of 1% of population each year – ten times more than the rate in Japan or West Virginia, the only US state with subzero growth – obviously decreases demand on the island but also potential growth as the labor force shrinks.

## PUERTO RICO – A WAY FORWARD

- **Energy costs.** Although they have fallen with oil prices, electricity costs of 22 cents per kilowatt hour are exceedingly high – similar to levels in less developed islands and several times the prices on the US mainland. As a key input cost, this cascades down to locally produced goods and services and stunts potential growth sectors such as tourism. Electricity is produced and distributed by an inefficient and over-staffed public enterprise (PREPA) using technologies decades out of date. A failure to tackle these issues satisfactorily has greatly undermined competitiveness.
- **Transport costs.** All islands, remote from the centers of economic activity, suffer from high transportation costs. But Puerto Rico does so disproportionately, with import costs at least twice as high as in neighboring islands on account of the Jones Act, which forces all shipping to and from US ports to be conducted with US vessels and crews. Even those that consider the negative effects of the Jones Act to be exaggerated – e.g., outbound cargo rates are lower than inbound ones, as ships would rather not return empty – concede it is a clear net negative. Puerto Rico also has local laws that add to transportation costs – specifically, prices and licensing requirements set by the Public Service Commission for ground transportation.
- **Barriers to competition and business activity.** A number of local laws and regulations restrict domestic competition and business investment. Puerto Rico’s rankings in the World Bank’s Doing Business Index slipped to 47 of 189 in 2015 (versus a #7 ranking for the US as a whole); in some areas, the rankings are decidedly bottom tier.

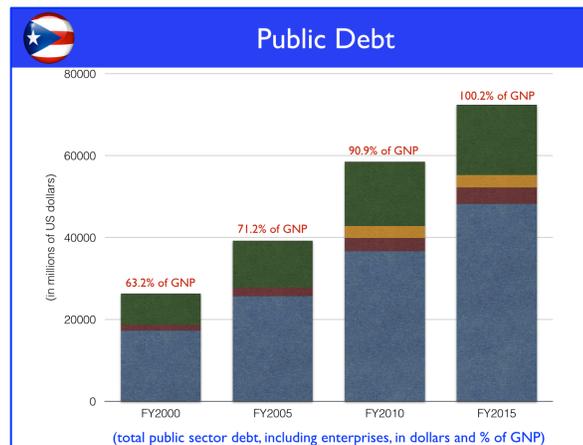

6. **These problems have shaped Puerto Rico’s economic structure, policies, and growth.** High minimum wages and welfare benefits have mostly hit unskilled employment in labor intensive sectors such as tourism; the number of tourist arrivals today is in fact lower than a decade ago, and the number of hotel beds about the same as in the 1970s. The high costs of labor and transportation have meant that Puerto Rico’s manufacturing sector is forced into high-value/low-weight/capital-intensive industries such as pharmaceuticals, bio-technology and software. The high cost of energy and water supply problems have also dissuaded numerous firms and industries from locating in Puerto Rico. To offset this high

input-cost structure, the government has had to resort to tax breaks to attract mainland and foreign direct investment – to the detriment of the tax system and the budget.

### III. FISCAL ORIGINS

*It is not just low growth that is casting a shadow over debt sustainability. Using standard IMF metrics, the overall deficit is larger than recognized, its true size obscured by incomplete accounting. This means that any fiscal adjustment program to restore market confidence starts in a deeper-than-assumed hole.*

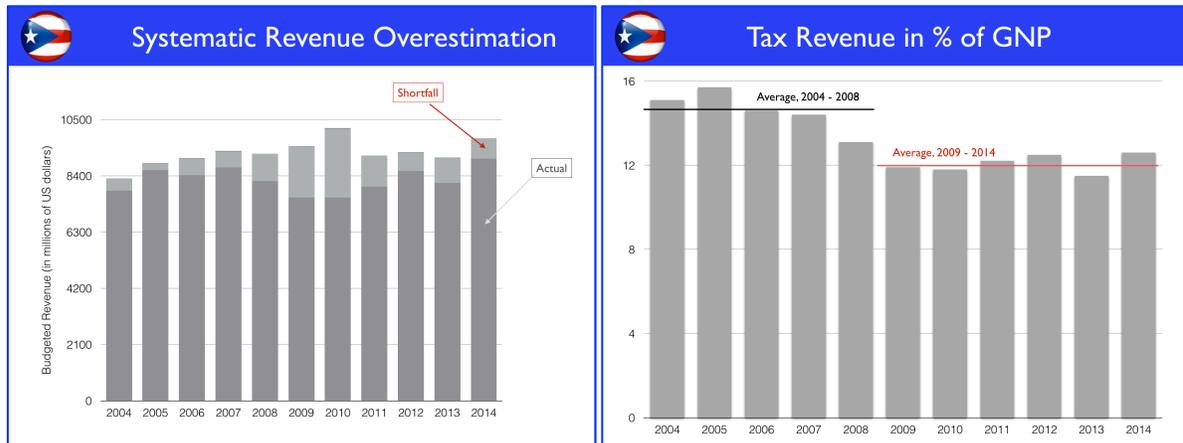

7. **Public sector debt has risen every year since 2000, through good years and bad ones, reaching 100 percent of GNP by end-FY 2014.** The central government and the three large public enterprises – the water and sewerage utility (PRASA), the state electricity company (PREPA), and the highway authority (HTA) – have been responsible for most of the increase in public debt. The fact that debt was rising even in years before the economy started to contract says something about the weakness in public finances. And how could debt continue climbing in the face of one emergency measure after another to “balance the budget” – from the sales tax in FY2006 to staff cuts in FY2009 to pension reform in FY2013?

8. **Persistent deficits reflect institutional factors, not just the weak economy:**

- *Overly optimistic revenue projections and budget formulation.* The Commonwealth’s budget is based on extremely optimistic revenue projections. Over the period FY2004-2014, and even excluding the Lehman shock year FY2009, revenue forecasts have systematically exceeded actual collections by some \$1.5 billion each year (15% of the original budget). The budget also systematically underestimates tax refunds due to the public from previous year filings. Revenue over-estimation happens in other places too – but rarely is it so consistently large. Moreover, tax revenues have slid markedly relative to nominal GNP, from over 15% of GNP prior to 2006 to around 12% of GNP, despite new measures implemented in the intervening period.

## PUERTO RICO – A WAY FORWARD

- Lack of expenditure control and the buildup of payables.* Midway in the fiscal year, the Office of Budget Management lowers its revenue forecast and assigns lower spending targets to agencies. But it has no enforcement power to oversee cuts. As a result, spending agencies continue to spend, accumulating unpaid bills that remain in their offices or sit temporarily unpaid at the Treasury. These payables used to be cleared at the start of the next fiscal year with fresh appropriations and debt issuances. But the stock of payables has been rising in recent years, lengthening the queue of unhappy suppliers and the time they must wait to be paid. There are also other problems with expenditure control, including tax verification of payrolls.
- Cash crunch and tax bargaining.* The near continuous pressure on the Treasury often brings government cash deposits down to precarious levels. To deal with this problem, in addition to delaying payables, the Treasury also tries to manage tax receipts. Sometimes, it offers tax amnesties; at other times, it offers a negotiated discount on the anticipated tax obligation if taxpayers pre-pay (closing agreements). While such practices raise needed cash, they also reduce incentives for prompt tax compliance and over time erode the tax base.
- Tax expenditure.* Although statutory tax rates are comparable to federal ones, Puerto Rico grants extensive tax credits and exemptions to attract investment – to alleviate the problem of the island’s high cost structure. For example, it is normal for firms to pay only 0-4% on their profits for 15 years (renewable); in addition, there are numerous tax credits and exemptions from income and excise taxes during and after the construction phase. Not surprisingly, collections have lagged behind the growth in manufacturing income. We have not quantified the foregone revenue/tax expenditure but there are estimates of \$250-500 million per year.
- Deficit monitoring.* The accounting systems in Puerto Rico do not permit timely and reliable monitoring of fiscal trends. The dense and hard-to-penetrate Consolidated Annual Fiscal Report (CAFR) is reliable but not timely – the latest accounts still relate to FY2013. By contrast, information on the Treasury’s General Fund operations is timely but partial, as explained below.

9. **The standard measure of the fiscal balance in Puerto Rico, using General Fund accounts, greatly understates the true deficit and the challenge ahead.** There are three fundamental problems. First, the General Fund is on a cash basis: if, say, the education department delays payments for school supplies, the purchase is not recorded as spending, thus understating the deficit. (Only a year later, after boxes of missing invoices have been hauled to the Treasury and recorded for the CAFR audit, does a truer picture emerge of the fiscal deficit on an accruals basis.) Second, the General Fund excludes numerous agencies – some 150 in total, including large ones like the health insurer ASES and smaller ones like the public buildings administration – that also run deficits, as well as the GDB, which operates like an arm of the government. Third, the General Fund excludes some \$300-400 million per year of capital expenditure; these too deplete cash balances or raise debt and must be counted. These missing items – missing due to the conceptual framework of the General Fund rather than any intention to mislead – are not accounting niceties but directly impact government operations. For example, if the interest payments the GDB has to make depletes its cash balances, this impacts the Commonwealth’s credit rating and market access – even if the General Fund cash deficit were zero. Similarly, if the numerous small agencies run large deficits, these reduce the cash balances available to the Commonwealth. An analysis of fiscal and debt sustainability cannot be conducted on so narrow a measure as the balance in the General Fund.

10. **Accordingly, we construct a measure of the deficit incorporating estimates of non-cash spending and a broader definition of central government.** First, to ensure that both cash and non-cash spending are captured in our metric, we begin by using the fact that the flow deficit must add up to (1) net debt issued to the private sector by the Commonwealth and the GDB; (2) the accumulation of payables (due to suppliers and tax refunds)<sup>2</sup>; (3) the run down of cash balances, and (4) other non-debt creating financing such as asset sales. This measure of the deficit, as used by the IMF, includes all of these financing items.<sup>3</sup> Second, we use a wider definition of the central government, which here is comprised of the Treasury and other primary government units (as defined in Puerto Rico), including those receiving formula-based budgetary transfers (e.g., University of Puerto Rico), the GDB and COFINA. To get the central government primary deficit, we add General Fund revenues, COFINA revenues, and the net operating surplus of the GDB (revenue less administrative expenses) and deduct General Fund expenses (excluding debt service), the net operating deficits (excluding debt service) of the primary units, non-enterprise component units (e.g., ASES), and capital expenditures; federal transfers and spending cancel out but are included as an indicator of the size of the central government in the economy. Effectively, the central government includes all parts of the public sector except the municipalities, the retirement funds, and the three large enterprises (PREPA, PRASA, and HTA).

<sup>2</sup> The payables here refer to macro-relevant arrears (e.g., for suppliers, wages, and tax refunds) and differ from the accounting concept (which includes items like accumulated vacation benefits).

<sup>3</sup> In principle, the GAAP analysis of the CAFR too incorporates the financing sources cited here – but it also includes asset and liability valuation effects, which are not really financing sources for the government and obscure the flow deficit relevant to fiscal policy. Our estimates for past years remove the latter effects.

11. **The primary and overall deficits estimated in Table 1 are larger and more problematic than generally understood.** The original budget objective in FY2015 was to run a surplus of revenue over non-debt expenditure (a primary surplus) sufficient to cover interest and amortization – what in the Commonwealth is called “balancing the budget”. In theory, had this occurred, cash balances and payables would have been unchanged and the debt stock would have declined by the amount of amortization. In practice, Table 1 shows that FY2015 will witness an alarming decline in cash balances and a further buildup of payables due to the fact that the \$850 million primary surplus is a far cry from interest and amortization costs of \$2.8 billion. The problem is not just that revenues are falling short while General Fund spending trundles along. It is also that there is other spending – on goods, services, interest and amortization – by entities other than the General Fund that is draining cash balances. This underlines the importance of using metrics that capture the full financing needs of the Commonwealth. Doing so brings the realization that the central government will be starting FY2016 in a deeper hole than understood, with the room for maneuver constrained by the loss of market access, dwindling cash balances, and a longer queue of disgruntled suppliers.

1/ Includes primary government agencies such as Public Buildings, the Medical Services Administration, and the Infrastructure Financing Authority (PRIFA).			
2/ Includes non-primary, non-enterprises, such as ASES.			

## 12. A similar narrative of large flow deficits applies to the wider public sector:

- The three big state enterprises and the employee and teacher retirement funds are also running deficits. Operational data and projections of the enterprises were made available and indicate that the enterprises are generally running overall deficits. The shutoff of market financing means that needed capital improvements, including those mandated by federal environmental laws, have been delayed.
- Although reforms have raised contribution rates and shifted the system away from a defined benefit regime, the continuing payout of previously accumulated rights has fully drained the liquid assets of the employee retirement system for government workers (ERS) and brought those of the teachers and judicial workers to low levels. The combination of high payouts for those with accumulated rights and few new contributors implies shortfalls that will ultimately fall on the central government.

13. **These flow deficits have worsened prospects for debt sustainability.** Consolidating the full public sector – central government, three enterprises, and two retirement funds – yields an overall deficit averaging 5% of GNP in FY2013 - FY2014. As nominal GNP growth is

barely 1%, flow deficits of this magnitude imply rising debt ratios, and explain the growing – if belated – concern in financial markets about the sustainability of public debt.

## IV. PROSPECTS UNDER CURRENT POLICIES

*Even if the recent sub-crisis situation could somehow persist (rather than worsen), current policies imply an unsustainable fiscal situation.*

14. **The near-term prospects for growth are poor – but we begin by positing something less bleak.** The reason is that we want to avoid drawing a strong negative conclusion about the fiscal outlook by *assumption* – i.e., by assuming a deteriorating growth outlook. The baseline scenario thus assumes that intermittent access to liquidity forestalls an overt financing crisis, and that real GDP growth somehow remains around -1%. The implied assumption of zero per capita income growth does not strike us as too pessimistic – if anything, it is probably *too optimistic*:

- The international experience is that financial market shocks have far more profound effects on economic activity than real shocks. Therefore, it is likely that investment will remain severely depressed on account of the financial turmoil and uncertainty.
- The forced contraction in the fiscal deficit, as well as the restriction of spending to the revenues coming in each month, will depress aggregate demand.
- The key housing/construction sector remains under pressure. The stock of vacant homes is still high and home prices may have further to fall. Given the centrality of home values as collateral, this will add to the downward pressure on credit.
- The longer-term structural problems persist: the labor force is still shrinking and there is little reason to think that competitiveness has improved.
- The one positive development, a significant one, is lower oil prices. However, the fact that activity indicators have continued to sink in spite of lower oil prices leads us to judge it inadequate to overcome all of the above.

The middle-through-baseline with -1% real growth and 2% inflation is merely an analytical construct to assess the *minimum* financing needs that arise over the next five years. A more realistic macro scenario might consist of a much sharper decline in output if a crisis were to materialize; alternatively, an early decline might be followed by recovery if pre-emptive actions are taken. We will return to the latter.

15. **Against this backdrop, central government deficits and amortizations over the coming years imply an unsustainable trajectory of large financing gaps (Table 2).** The projections focus on FY2016-2020 but, to better convey the challenges, have been extended to FY2025. The baseline uses OMB projections for coming years but does not include the

## PUERTO RICO – A WAY FORWARD

progress on the sales tax reform (which is taken into account later on). The result is overall deficits of some \$2½ billion per year (3½ % of GNP) over the next five years; this projection includes budgetary support for the Employee Retirement Fund starting in FY2017, for the judiciary starting in FY2019, and for teachers starting in FY2020. Further, there are: (i) amortizations; (ii) gradual pay down of arrears to suppliers and taxpayers (\$450 million per year); and (iii) downside risks from a potential loss of federal funding for the Affordable Care Act and from a decline in Law 154 excises (due to modified source income accounting rules for firms operating in multiple tax jurisdictions). After factoring these in, the total financing gap ranges from \$3½-8¼ billion per year through FY2025. If market access were open, central government debt would more than double by FY2025. But since that is neither sustainable nor feasible, financing gaps will have to be closed through policy action.

1/ Includes petroleum tax (PET) net receipts as a revenue source for the GDB in 2016-2025.											
2/ Includes primary government agencies such as Public Buildings, the Medical Services Administration, and the Infrastructure Financing Authority (PRIFA).											
3/ Includes non-primary non-enterprises, such as ASES (healthcare agency) and the bus and ferry mass transit authority (from 2016 on).											
4/ As in many of the projections, the actual outcome could be worse. For example, in the absence of reform of the healthcare system the cost here could reach \$2 billion by 2019 and the gap in the retirement funds could be larger in the absence of strict adherence to increasing contribution rates.											

16. **The financial situation of the public sector enterprises is also precarious.** The projections assume that the central government will have to assume loss-making operations of the highway authority to keep it afloat. The electric utility PREPA is already operating on

a pure cash basis; until its situation with its creditors is regularized, it accumulates interest and amortization arrears of over \$600 million per year. The water and sewage company PRASA is not projected to generate enough revenues to cover EPA-mandated investments.

## V. A STRATEGY FOR GROWTH AND CONFIDENCE

*The restoration of confidence and growth requires ambitious measures in three inter-locking areas: structural reform, fiscal consolidation/debt restructuring, and institutional reform. All are important, and the exclusion of any one reduces the chances of success of the others.*

17. **The key to turning around Puerto Rico’s situation is a revival of growth.** The island has many problems but they all result in the same outcome – a lack of growth. Structural rigidities have compromised competitiveness and yielded stagnation. Weak fiscal discipline has resulted in uncertainty that is further depressing economic activity and employment. Low growth feeds back to strains on revenue and spending. It is a vicious circle.

18. **A comprehensive approach is needed.** The problems are too interdependent. For example, fiscal adjustment alone might strengthen confidence in long-term public finances and thereby support demand. But too much fiscal tightening could also depress demand in the near-term and would do nothing to address the supply side problems at the root of Puerto Rico’s growth problem. Similarly, structural reforms alone would still leave large fiscal financing gaps. Hence the need for complementary structural reforms to boost growth and debt restructuring to avoid an economically harsh and politically unviable cut in the fiscal deficit. A combination of structural reforms, fiscal adjustment, and debt restructuring ensures that all problems are addressed. And, importantly, it shares the costs and benefits of adjustment across all stakeholders.

19. **Puerto Rico’s record of failed partial solutions also argues for a comprehensive approach.** Over the years, successive administrations put in place important and even lasting policy responses. However, they focused on fiscal deficits, not economic growth. Moreover, even the narrow approach was implemented in an ad hoc manner in response to immediate pressures rather than in a forward-looking way that acknowledged the scope of fiscal problems. Thus, the introduction of the sales tax in FY2006 was followed by a fiscal emergency to cut government staffing in FY2009, by reform of public employee and teacher pensions in FY2013, by the petroleum tax in FY2014, and most recently by the attempted VAT reform – each presented as a durable solution to the island’s problems. Puerto Rico’s current predicament reflects its unsustainable policies but also a lack of confidence in its preparedness to change course.

20. **Establishing a new and credible strategy will be challenging.** The needed measures face domestic political resistance (e.g., on labor laws and cutting fiscal deficits), federal inertia (e.g., on exemptions to the minimum wage and the Jones Act), legal challenges (e.g., on debt restructuring), and organizational difficulties in keeping the program on track. New institutions to establish budget discipline and data transparency will need to be created. All

this will fully occupy the administration. But so would *not* implementing a comprehensive solution, which might usher in an even more severe and harder-to-manage crisis.

## A. STRUCTURAL REFORMS

*Supply-side reforms are fundamental to any lasting economic recovery but will take time to implement and to bear fruit.*

21. **Puerto Rico has many advantages to build on but also important disadvantages, some within its power to tackle and some requiring federal help.** Among the advantages are its natural gifts as a tropical island, the size of its college-educated and bilingual population, its sizable manufacturing base, its situation as an integral part of the United States, with all the attendant benefits in terms of currency stability, legal system, property rights, and federal backing of welfare, education, defense, and banking. That is a lot. At the same time, there are numerous policy failures that raise input costs and stifle growth. While some of these are within the Commonwealth's power to fix (such as local labor regulations), others lie in the remit of the federal government and the US Congress (the minimum wage and welfare rules, the Jones Act, and Chapter 9 bankruptcy eligibility). If these could be overcome, there is no reason why Puerto Rico could not grow in new directions – likely ones like tourism, possible ones like serving as a financial/services hub between North and South America, and entirely unpredictable ones because that is how reforms have played out elsewhere. Reducing input costs for labor, energy and transport is key to regaining competitiveness, so that production can be geared to more buoyant external markets.

22. **A fresh start on structural reforms should begin with the recognition that supply-side reforms take time.** Partly this is because reforms are hard to formulate and legislate. Partly it is because, even after being implemented, it takes time for people to perceive the change and to gain confidence that reforms will stick and not be reversed by the next administration. The impact on growth could take 2-4 years to become apparent, less when (a) there is a prior history of successful reforms; (b) the strategy and details are effectively communicated; (c) all segments of society share in the reform effort's near-term costs and long-term gains; and (d) the program as a whole is credible, with upfront delivery of key reforms. Experience also teaches that while the goals should be clear at the start, structural reform is more a process than a check-list: the details need to evolve with circumstances.

23. **To raise employment, it is imperative to remove the disincentives for firms to hire workers and for workers to accept jobs.** As suggested earlier, the key issues are as follows:

- The US federal minimum wage of \$7.25 per hour is too high relative to local incomes and regional competitors. Puerto Rico should seek an exemption until such time as its per capita income approaches that of the poorest US state, which currently is still 50% higher than Puerto Rico's. If full exemption is not possible, then an alternative might be to set the rate for Puerto Rico at one-third the general rate (per capita income in Puerto Rico is about one-third that on the mainland).

- Local labor laws magnify employment costs. Undoing this entails: (i) redefining overtime as on the mainland (excess over a 40-hour week, not 8-hour day); (ii) cutting paid vacation days to mainland levels (for public sector workers, from 30 days to 15 days); (iii) eliminating the mandatory end-of-year bonus; (iv) reducing onerous requirements for proving just cause in layoffs to mainland levels; (v) extending the probationary period for new employees from 3 months to 1-2 years; and (vi) relaxing labor laws for youth/new entrants for the first few years.
- Federal welfare payments are generous relative to the low incomes in Puerto Rico, and as such are a disincentive for the unskilled to accept work (lest they lose benefits). Welfare needs to be made consistent with local labor market conditions rather than with US mainland conditions. The federal government should therefore give the Commonwealth more latitude to adjust welfare requirements and benefits – e.g., to continue food stamps for a while even after a person returns to work; or to provide lower housing benefits to more people rather than higher benefits to a few (the Commonwealth block grant is capped and insufficient for all those who qualify). Puerto Rico too can act here, cutting back the Medicaid benefits it pays out over and above the Federal minimum standard (thus saving some \$150 million per year).

24. **Exempting Puerto Rico from the US Jones Act could significantly reduce transport costs and open up new sectors for future growth.** In no mainland state does the Jones Act have so profound an effect on the cost structure as in Puerto Rico. Furthermore, there are precedents for exempting islands, notably the US Virgin Islands. Puerto Rico should also eliminate its own self-imposed costs by freeing up the scope for competition in ground transportation and liberalizing the associated prices set by the Public Service Commission.

25. **The drive for competitiveness must include a cut in high energy costs, which cascade down to the rest of the economy.** The silver lining in PREPA's financial difficulties is that it has forced the public enterprise to confront its problems of over-staffing and inefficiency. The specifics of upcoming reforms, and the associated debt relief to make it viable, are still being worked out by PREPA and its creditors. Whatever the details, they should build to a solution where PREPA focuses on transmission and distribution, while electricity generation is opened up to competition from newer and more efficient suppliers.

26. **A lot can be done to lighten the burden of doing business, which is particularly important when reforms are aiming to move the economy in new directions.** To date, the term business-friendly in Puerto Rico has referred to efforts to offset high input costs with tax breaks and subsidies. As input costs are brought down, the focus should shift to ensuring a level playing field and greater ease of doing business, including permits for new businesses. This is always an on-going task but a start could be made by addressing the three weakest areas identified by the World Bank: the difficulty in registering property, in paying taxes, and in obtaining construction permits. There is already some progress to build on, notably a plan to modernize property registration. Lest this sort of work slip into

obscurity in the press of a crisis, the task should be assigned to a high-level official held accountable for pulling up the Commonwealth's score in future Doing Business rankings.

## B. FISCAL ADJUSTMENT AND PUBLIC DEBT

*Given looming revenue and spending pressures, eliminating the fiscal deficit will take substantial measures. Reforms should aim more at broadening tax bases than raising rates, and at targeted expenditure reduction rather than across-the-board cuts. But even a major fiscal effort leaves large residual financing gaps that will need to be bridged with debt relief.*

27. **Table 3 illustrates a scenario where revenue and expenditure substantially reduce the total financing gap in coming years.** The measures set out below, along with the revenue enhancing effects of structural reform, would eliminate the overall budget deficit by FY2020. Given the starting point of fiscal unsustainability, this is important. At the same time, the adjustment scenario tries to be as growth friendly as possible, avoiding too sharp a contraction in the near-term, and focuses more on broadening tax bases than on raising tax rates. The measures below are, in our view, sensible and feasible. But there are undoubtedly other sensible and feasible options the government will also want to explore.

28. **On the revenue side, there is scope to raise receipts by \$1 billion in FY2016, around \$3 billion annually by FY2020 and \$4 billion annually by FY2025.** Some possible measures:

## PUERTO RICO – A WAY FORWARD

- Adoption of a sales tax as proposed by the administration; this could yield just over \$1 billion in FY2016.
- A surcharge on the corporate income tax that would also cover firms currently paying only 0-4% (versus the statutory 35%). This should be seen as a first step to an eventual overhaul that replaces widespread exemptions with a low flat rate of 10-15%; this is assumed to yield \$250 million starting in FY2017 and to rise quickly after that.
- A step up in property taxes (currently based on real estate values from 1954); updating the registry and adjusting down tax rates could yield \$100 million in FY2016 and more in later years as the project takes off (a target of 1% of GNP is reasonable). This is shown in Table 3 as a revenue measure but could equally be treated as a spending measure: since municipalities normally retain property taxes, the central government revenue could cut its transfers to municipalities by the amount of additional property tax receipts.
- Rising income tax collections from higher worker participation due to labor reforms; the amount raised is assumed to be a modest \$50 million in early years but grows quickly.

The payoffs from the above are indicative and obviously will depend on details that have yet to be worked out. Substantial additional revenue might also accrue from improved tax collection, which is low relative to statutory rates not just due to exemptions but also due to poor compliance; no assumptions regarding improved compliance are made at this stage.

**29. On the expenditure side, there is scope to save over \$2 billion per year by FY2020 and \$2½ billion per year by FY2025:**

- Renewing Law 66 (freeze of certain formula-based transfers from the general fund) and freezing remaining spending in real terms saves \$1 billion by FY2020. Capital/infrastructure is assumed flat but could be raised if revenues exceed expectations.
- Puerto Rico currently has 40% fewer students but 10% more teachers than a decade ago. Teacher-student ratios are high, higher than in the mainland and many of its wealthiest and best-performing counties. A gradual cut in the number of teachers saves \$400 million per year by FY2020 – more if sparsely attended schools are also consolidated. The one-off costs of retrenchment should be met by one-off revenues, e.g., if valuable/cash-rich enterprises like the state insurance fund are privatized.
- A reduction in the subsidy for the University of Puerto Rico. College students currently pay a low flat rate that for many is far lower than on the mainland and far lower than what well-off UPR students paid for private high school. Rather than a blanket subsidy, support should be provided through need-based scholarship. A program along these lines could save up to \$500 million by FY2020.
- Cuts in Medicaid benefits in excess of minimum standards on the US mainland. This could save an estimated \$150 million per year.

Despite these cuts, total expenditure would still rise in dollar terms and relative to GNP as it is assumed that the government makes up for any cash shortfalls of the retirement funds.

30. **The fiscal benefits of comprehensive reform should also be factored in.** The bottom of Table 3 sets out a higher growth path than assumed so far. The difference between a trend real GNP growth of -1% and of +2.5% delivers additional revenue of some 2½% of GNP by FY2025, which is built into the projections of the residual financing gap after measures.

31. **The quantitative estimates in Table 3 are subject to great uncertainty and do not reflect the full menu of policy options.** Apart from known unknowns such as the size of declines in Law 154 excise receipts, the baseline financing gap projections are subject to numerous other assumptions (e.g., the rate at which payables are brought down) and do not cover all government reform needs (e.g., retirement system funding). The impact of measures also hard to predict and depend on the timing and specifics. Could the measures be enhanced or made more front loaded? Perhaps but not easily. Even if enacted quickly, it would be imprudent to assume large revenue increases in the first year of an adjustment program, when economic pressures and implementation difficulties are at their most intense. The payoff is especially unclear with regard to the corporate tax surcharge – although the need to claw back decades of exemptions and tax spending is acute.

32. **Even after factoring in a major fiscal effort, a large residual financing gap persists into the next decade – implying a need for debt relief.** On the assumptions embodied in Table 3, to close the residual financing gap, the government would need to seek relief from a significant – but progressively declining – proportion of the principal and interest falling due during FY2016-23 the residual financing gap disappears by FY2024. The precise amount of debt relief will need to be calibrated to the specifics of the reform and the likely path of the economy, both of which are uncertain at this stage.

33. **Debt relief could be obtained through a voluntary exchange of old bonds for new ones with a later/lower debt service profile.** To agree to it, bondholders would need to be convinced that the specific reforms on the table are indeed a best use of debt relief, and that – by keeping the government functioning as it phases in organizationally and politically difficult measures – the reform program will increase the expected value of their claims. Negotiations with creditors will doubtlessly be challenging: there is no US precedent for anything of this scale and scope, and there is the added complication of extensive pledging of specific revenue streams to specific debts. But difficult or not, the projections are clear that the issue can no longer be avoided.

34. **Any discussion with creditors on general obligation debt should be coordinated with the parallel one being conducted by public enterprises.** The government will need to coordinate its own discussions on general obligation debt with those already in progress for public enterprises – not least because creditors too, like the government, will look at the overall resource envelope and investment needs in public enterprises. To facilitate a more orderly discussion of debt, it would help if the US Congress were to remove the explicit exclusion of Puerto Rico from the provisions of Chapter 9 of the US bankruptcy code.

## C. INSTITUTIONS AND CREDIBILITY

*The legacy of budgetary laxity, non-transparency, and unreliable/dated statistics must be overcome if the reform program is to work and command credibility. The priorities include a rolling 5-year budgetary plan approved by the legislature, legislative rules to limit changes to the plan, an independent fiscal oversight board to advise on the budget and control its implementation, and strengthening the quality and timeliness of economic data.*

35. **The first step must be legislative approval of a long-term fiscal plan.** Broad political backing for the fiscal adjustment plan – for all five years of the adjustment, not just for FY2016 – will be crucial to its credibility. To limit the scope for deviations, the legislature should consider adopting rules that either force across-the-board spending cuts (a Gramm-Rudman rule) or else some combination of spending cuts and tax increases (a PAYGO rule) if any subsequent measure or event causes the projected fiscal deficit to deviate from its planned path. Experience shows that such legislative rules can improve fiscal discipline, but cannot ensure it, as they work by restraining fiscal plans rather than fiscal outcomes.

36. **An independent fiscal oversight board can improve fiscal outcomes.** The group, comprised of experienced individuals from inside and outside the Commonwealth, would vet the current year's budget and the rolling 5-year fiscal plan prior to submission to the legislature; it would also have special powers to enforce approved budgets. These powers are needed because of Puerto Rico's legacy of overly-optimistic budget estimates and of failure to control spending even when it is clear that revenue targets will not be met. Effective expenditure control will take more than an oversight board at the top. It will also take uniform data and reporting requirements across all spending agencies – spending units currently employ different IT systems – as well as internal coordination. The existing single treasury account needs to be employed as an expenditure control mechanism as well as its current use as a centralized payment system. Notwithstanding the logistical challenges, consideration should be given to merging the operations of the Government Development Bank and the Commonwealth Treasury (Hacienda). The functional overlap is significant, while coordination is hindered by differences in formal roles and governance structures.

37. **Greater transparency in the provision of fiscal data could also enhance market discipline.** As discussed earlier, the published quarterly figures are too narrow in scope to provide an accurate picture, while the CAFR consolidated accounts appear with a long lag and are difficult to interpret. Analysts should not have to engage in jujitsu with the data in order to figure out the fiscal deficit. The data will need to be put in a standardized format, as has been done in this report, and published in regular updates.

38. **Finally, statistics on the wider economy need to be strengthened – urgently.** The problems with the national accounts are severe. The US Bureau of Economic Analysis has a report on what needs to be fixed but a lack of resources has limited progress. Consideration should be given to consolidating the relevant statistics providers and giving them necessary funding. Better statistics are not a luxury. Without them the Commonwealth is flying blind

and market uncertainty about underlying developments is reflected in the risk premium on government debt. Improved statistics and data transparency could pay for themselves.

## VI. OBJECTIONS AND RESPONSES

*This section subjects some of the above arguments to a stress test of counterarguments – not to pre-empt objections but to probe into the thinking behind the analysis.*

39. **Objections – growth.** Some might wonder if the report is too pessimistic on near-term prospects. After all, there are positive signs. Private employment has stopped falling; the GDB’s economic activity index has improved; and many individual sectors are doing well, including tourism, agriculture, and increasingly aeronautics. It could also be argued that official figures underestimate growth on account of overestimated price deflators.

40. **Response.** Fine but the improvements are too small, narrowly focused, recent – and dwarfed by the gorilla in the room: the damage from a decade of stagnation and the cutoff of market access, which experience tells us has severe negative effects on credit, investment, and consumption. More generally, Puerto Rico is suffering from protracted supply side problems, its growth potential eroding in the face of a shrinking labor force, narrowing manufacturing base and depreciating capital stock. Turning this around will take time and more ambitious action. Finally, on GNP statistics, the overestimation of price deflators is not the only problem: *nominal* GNP may also be overstated, in which case lower price deflators do not necessarily yield higher real growth estimates.

41. **Objections – Puerto Rico structural reforms.** Many will doubt that upfront action in so many structural areas is feasible in Puerto Rico. The reforms are difficult enough individually. Attempting all at once risks overloading the political circuits.

42. **Response.** The government is better positioned than we are to assess political feasibility. Certainly, many countries have found ways to muster support for comprehensive reforms, albeit usually in the context of international support. But, support or no support, the island has little choice now but to press ahead. It has tried gradual and partial solutions to no avail. The crisis can concentrate minds in the political system to suspend “business as usual” and attend to all that has gone untended for years – it ought to get on with this regardless of the speed of federal action. Not all action need be up front but there should be enough up front to make it credible, with a clear road map of further reforms and where they lead. Importantly, the proposed package shares the costs of reform – lower wages for labor, fewer tax exemptions for business, debt re-profiling for creditors – while holding out the prospect of renewed confidence and growth, which benefits all.

43. **Objections – federal structural reforms.** Why not focus on something simpler like reviving US tax preferences? Many consider it naïve to think that the US Congress would modify labor and transportation laws intended for all of the United States just to help out

Puerto Rico. It may be easier to push for something that the Congress has agreed to before – tax preferences, the loss of which is anyway the original sin behind the island’s travails.

44. *Response.* Reforms in labor, transport, and bankruptcy laws are economically essential. They may face political resistance in Washington DC but Puerto Rico has a case to make. On reinstating US tax preferences, it is not clear that this is an easier ask for the US Congress. Or that mainland firms would necessarily be lured to the island, as exemptions can – and have – been withdrawn before. Or indeed that a growth model founded on tax advantages is better in the long run than one based on genuine competitiveness.

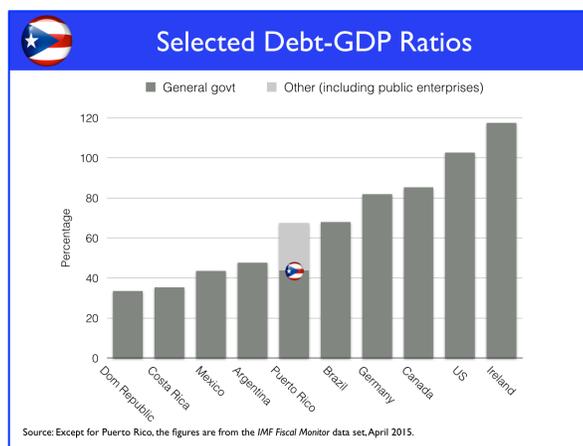

45. *Objections – minimum wage.* Even if one accepts that there may eventually be positive effects on hiring from lower wages, one has also to take into account that lower wage earnings by the currently employed will reduce domestic spending and growth.

46. *Response.* First, it is unlikely that a reduction in the minimum wage will induce an instantaneous fall in all wages in Puerto Rico. The downward pressure on wages, like the upward pressure on employment, will take time to play out; and anyway, below minimum-wage market wages already exist in the large informal sector. Second, even if currently employed workers reduce their spending by some fraction of lost earnings, this should be offset – more than offset – by the higher spending of the newly employed. Third, labor reform should be seen in a wider context of the effort to restore confidence in future growth, which should raise consumption and investment.

47. *Objections – pace of fiscal adjustment.* Some observers might point to the contrasting experiences of Ireland and Greece with fiscal adjustment. Ireland, in many ways similar Puerto Rico (a large resident base of multinational firms, a recent housing bust, low corporate taxes), had much better growth outcomes partly because it had a more gradual fiscal adjustment than Greece. Puerto Rico should heed the lesson that fiscal multiplier effects are high in crisis situations, and so reduce its fiscal deficit only gradually.

48. *Response.* There was scope for slower fiscal adjustment in Ireland because off-market financing was made available to it by Euro zone partners and the IMF. Ireland’s policy credibility was also enhanced by quarterly EC/IMF monitoring of program implementation, and by the fact that its fiscal problem was not decades old but the result of a banking crisis. These points do not apply to Puerto Rico, thus limiting its options. That said, Puerto Rico does have scope to generate some financing by reprofiling part of the debt service falling due, and having the adjustment effort overseen by a fiscal oversight board. Ultimately, Puerto Rico needs to strike a balance between the demands of financing, credibility and growth – which is what the fiscal adjustment scenario here tries to do.

49. *Objection – debt burden.* Many people argue that Puerto Rico’s debt ratios aren’t bad by international standards, especially if the Commonwealth’s ratio is calculated relative to *GDP* (not *GNP*, which is much lower) and public enterprises are excluded (as in other countries). They argue that Puerto Rico’s problem is not too high debt but too high deficits.

50. **Response.** Regardless of whether public enterprise debt is included or not, or deflated by GDP rather than GNP, the fact is that Puerto Rico's situation is worse than simple debt ratios suggest because the island is laboring under near-zero *nominal* GNP/GDP growth. This inevitably forces up debt ratios over time. None of the other countries in the chart is in this situation. On inclusion of enterprises in public debt statistics, that hinges on whether the government can, as a practical matter, maintain a hands off financial relationship with enterprises. Could Puerto Rico countenance an interruption – prolonged by the absence of Chapter 9 bankruptcy provisions – in the electricity, water and transportation services provided by public enterprises? Probably not.

51. **Objection – restructuring general obligation debt.** To some, it seems quixotic to try to restructure Puerto Rico central government debt given that (1) the Commonwealth's constitution prioritizes these obligations; (2) the task is complicated by the extensiveness of pledged revenues; and (3) no US state has restructured its general obligation debt in living memory. Any attempt faces unprecedented legal challenges. Moreover, in the absence of an IMF or debtor-in-possession creditor for Puerto Rico during a potentially drawn out legal process, the government's capacity to provide essential services would be compromised. Rather than a formal restructuring process, it would be preferable to raise taxes and cut spending by a lot more, thus inducing creditors to voluntarily roll over maturing debt.

52. **Response.** A decision to restructure debt, even via a market-friendly debt exchange, is never taken lightly. The legal challenges are indeed a complex issue for the government's legal advisors. But from an economic perspective, the fact remains that the central government faces huge financing gaps even *with* substantial adjustment efforts. There are limits to how much more expenditures can be cut or taxes raised. A tax to GNP ratio of 12-13% may seem low by US standards (it is similar to states, but the latter also pay federal taxes from which Puerto Rico is exempt). However, statutory *tax rates* are high in Puerto Rico, similar to federal rates, and – before contemplating further hikes – one has to be mindful of the already large informal economy, and the hit to near-term growth from a sharper fiscal contraction; if output falls significantly, tax receipts will decline. Too much fiscal adjustment also raises questions about fair burden sharing between creditors and taxpayers, and puts at risk the political viability of the overall reform effort. These thoughts

will also occur to creditors when they assess the credibility of a sharper fiscal response – a mere show of fiscal austerity will not necessarily induce them to roll over maturing debt. Yes formal debt restructuring without an IMF or debtor-in-possession lender in the background carries risks. But so does unrealistically high fiscal adjustment and the rollover of debt at unaffordable interest rates and seniority.

## VII. CONCLUDING THOUGHTS

*The situation is acute in the face of faltering economic activity, faltering fiscal and debt sustainability, and faltering policy credibility. A comprehensive program that tackles all three has a better chance of success than a partial approach, and the advantage of sharing the costs and benefits of reform across government, workers, businesses, and creditors.*

53. **The measures to date are important first steps that need to be built on to deal with a situation years in the making.** Credit must be given to the current administration for putting in place important measures – higher taxes, pension reforms and spending cuts and freezes – to try and stabilize public finances. These measures were necessary but incomplete. The shortcoming has been to view the problem as one of cash flow: if only the Commonwealth had more time and loans, fiscal efforts would turn around confidence and the economy. But the problem of negative growth, a non-starter for debt sustainability, is structural. The problem of the fiscal hole is larger than recognized and set to deteriorate. The problem of policy credibility – from poor fiscal control to inaccurate and dated statistics to lack of political consensus – is as severe as ever.

54. **The debt crisis is not just a fiscal one but also reflects structural problems that have held back growth – both need to be tackled together.** There will be a temptation to focus on the fiscal side because it is more in the administration's direct control. This is not surprising and, indeed, has been the norm in the last decade, which has seen a series of fiscal measures presented as complete answers to the island's ills. Structural reform is harder: explaining that real wages are too high is a hard sell, as is getting the US Congress to exempt Puerto Rico from federal laws that especially disadvantage it (minimum wage, Jones Act, Chapter 9 bankruptcy). Many will dismiss structural reforms as too difficult, too woolly or too long term. But we are convinced that structural reforms are critical to growth, and that without growth, the chances of success are dim. The problems of growth, of credibility, of public debt – all cast a shadow on each other and must be tackled together.

55. **The policy agenda is daunting but similar challenges have been overcome elsewhere and can be in Puerto Rico too.** It will be especially important to establish the credibility of the reform effort early on in the process. This will require up front action and new institutional mechanisms such as a fiscal oversight board. The government should also consider appointing a senior official to coordinate the effort, as well as specific individuals to deliver reforms that would otherwise fall between the cracks in the press of a crisis (e.g., reforms to strengthen the business climate and the provision of data). All this is a heavy lift but also one within the capacity of Puerto Rico to accomplish.

# Puerto Rico Fiscal and Economic Growth Plan

*Prepared by the Working Group for the Fiscal and Economic Recovery of Puerto Rico Pursuant to Executive Order 2015-022*

September 9, 2015

# Disclaimer

---

- The Working Group for the Fiscal and Economic Recovery of Puerto Rico (the “Working Group”), the Commonwealth of Puerto Rico (the “Commonwealth”), the Government Development Bank for Puerto Rico (the “GDB”) and each of their respective officers, directors, employees, agents, attorneys, advisors, members, partners or affiliates (collectively with the Commonwealth and the GDB, the “Parties”) make no representation or warranty, express or implied, to any third party with respect to the information contained herein and all Parties expressly disclaim any such representations or warranties.
- The Parties do not owe or accept any duty or responsibility to any reader or recipient of this presentation, whether in contract or tort, and shall not be liable for or in respect of any loss, damage (including without limitation consequential damages or lost profits) or expense of whatsoever nature of such third party that may be caused by, or alleged to be caused by, the use of this presentation or that is otherwise consequent upon the gaining of access to this document by such third party.
- This document does not constitute an audit conducted in accordance with generally accepted auditing standards, an examination of internal controls or other attestation or review services in accordance with standards established by the American Institute of Certified Public Accountants or any other organization. Accordingly, the Parties do not express an opinion or any other form of assurance on the financial statements or any financial or other information or the internal controls of the Commonwealth and the information contained herein.
- Any statements and assumptions contained in this document, whether forward-looking or historical, are not guarantees of future performance and involve certain risks, uncertainties, estimates and other assumptions made in this document. The economic and financial condition of the Commonwealth and its instrumentalities is affected by various financial, social, economic, environmental and political factors. These factors can be very complex, may vary from one fiscal year to the next and are frequently the result of actions taken or not taken, not only by the Commonwealth and its agencies and instrumentalities, but also by entities such as the government of the United States. Because of the uncertainty and unpredictability of these factors, their impact cannot be included in the assumptions contained in this document. Future events and actual results may differ materially from any estimates, projections, or statements contained herein. Nothing in this document should be considered as an express or implied commitment to do or take, or to refrain from taking, any action by the Commonwealth, the GDB, or any government instrumentality in the Commonwealth or an admission of any fact or future event. Nothing in this document shall be considered a solicitation, recommendation or advice to any person to participate, pursue or support a particular course of action or transaction, to purchase or sell any security, or to make any investment decision.
- By accepting this document, the recipient shall be deemed to have acknowledged and agreed to the terms of these limitations.

# Executive Summary

# Executive Summary

**This document contains the key findings of the Working Group for the Fiscal and Economic Recovery of Puerto Rico (the “Working Group”) established by Governor Alejandro García Padilla by executive order (EO 2015-022), and the measures recommended by the Working Group to reduce the Commonwealth’s projected financing gaps. Such measures comprise the “Fiscal and Economic Growth Plan” or “FEGP”.**

- Despite the significant historical measures undertaken by the Commonwealth since the onset of the financial crisis in 2007 to reduce expenses, increase revenues and address structural challenges, the Working Group projects that, absent meaningful additional fiscal and structural reforms, the consolidated government will incur significant financing gaps for at least the next five years
  - The cumulative financing gap for the Commonwealth is projected to be \$27.8 billion from fiscal year (“FY”) 2016 to FY 2020 absent corrective action
  - In addition, the Puerto Rico Treasury’s single cash account (the “TSA”<sup>(1)</sup>) and the Government Development Bank for Puerto Rico (the “GDB”) are each expected to exhaust their liquidity before the end of calendar year 2015
- In connection with this fiscal and economic emergency, the Working Group and its advisors examined the various causes of the fiscal and economic challenges facing the Commonwealth, and potential reform measures to address these challenges
- Following this review, the Working Group developed the FEGP, setting forth economic development, structural, fiscal and institutional reform measures intended to meaningfully reduce the Commonwealth’s projected financing gaps
  - The Working Group believes that the Commonwealth could reduce its cumulative financing gap by over \$11.9 billion from FY 2016 to FY 2020, through a combination of revenue increases and expense reductions<sup>(2)</sup>
    - ☞ Economic growth, if achieved, could reduce the cumulative financing gap another \$1.9 billion

(1) The TSA account is the account through which General Fund’s (as that term is used in the Commonwealth’s comprehensive annual financial reports) expenses flow as well as certain other governmental funds. It excludes GDB balances and public corporations such as HTA (though certain tax revenues collected by the Commonwealth before transfer to a public corporation do flow through the TSA).

(2) Net of assumed incremental costs associated with these measures.

# Executive Summary

---

- In order to ensure compliance with the FEGP measures, the Working Group proposes the implementation of a control board and new budgetary regulations, pursuant to proposed legislation known as the Fiscal Responsibility and Economic Revitalization Act (“FRERA”)
- In addition to the local policy reforms, the Working Group believes that meaningful changes to US federal policies are critical to the ability of the Commonwealth to meet its debt service costs while providing funding for essential services to its residents, most particularly changes in the areas of health care funding and tax policies for economic development. Moreover, the Working Group believes Puerto Rico must have an orderly process to restructure its liabilities
- Even after the implementation of the FEGP, which is subject to significant political and execution risks, the Working Group’s projections suggest that the Commonwealth cannot meet all of its debt service requirements as currently scheduled and must restructure its liabilities
  - After accounting for the estimated impact of all measures *and* including the benefit of potential economic growth spurred by structural reforms, the Working Group still projects the Commonwealth to have a cumulative financing gap from FY 2016 to FY 2020 of \$14 billion
- While the Working Group recognizes that a restructuring of the Commonwealth’s debt would result in hardship to individual bondholders, unless the persistent stagnation of Puerto Rico’s economy that has helped fuel the increase in Government debt over the past decade can be reversed, the public debt is not sustainable
  - Further, paying debt service as currently scheduled in the face of significant financing gaps could severely impair the Commonwealth’s ability to provide essential services to its residents

# Executive Summary

---

- As difficult as debt restructuring is likely to be (particularly in the absence of an effective federal or Commonwealth public debt restructuring legal framework), the Working Group recommends that the Commonwealth advisors begin work on a voluntary exchange offer to be made to its creditors as part of the implementation of the FEGP
- The Working Group has directed the Commonwealth’s advisors to take into account the priority accorded to various debt instruments across the Puerto Rico debt complex while recognizing that, even assuming the clawback of revenues supporting certain Commonwealth tax supported debt, available resources may be insufficient to service all principal and interest on debt that has a constitutional priority
- Therefore, a consensual compromise of the creditors’ competing claims to the Commonwealth’s revenues to support debt service will be required in order to avoid a disorderly default on the Commonwealth’s debt and a legal morass that will further destabilize the Commonwealth’s economy and finances
- Accordingly, the Working Group recommends that the Commonwealth advisors meet with the creditor groups that have already been organized (and those that may be formed hereafter) to explain the Fiscal and Economic Growth Plan and to begin negotiation of the terms of a voluntary exchange offer that can garner widespread creditor acceptance
- **It is the Working Group’s belief that a voluntary adjustment of the terms of the Commonwealth’s debt that allows the measures contained in the FEGP to be implemented is the best way to maximize all creditor recoveries**

---

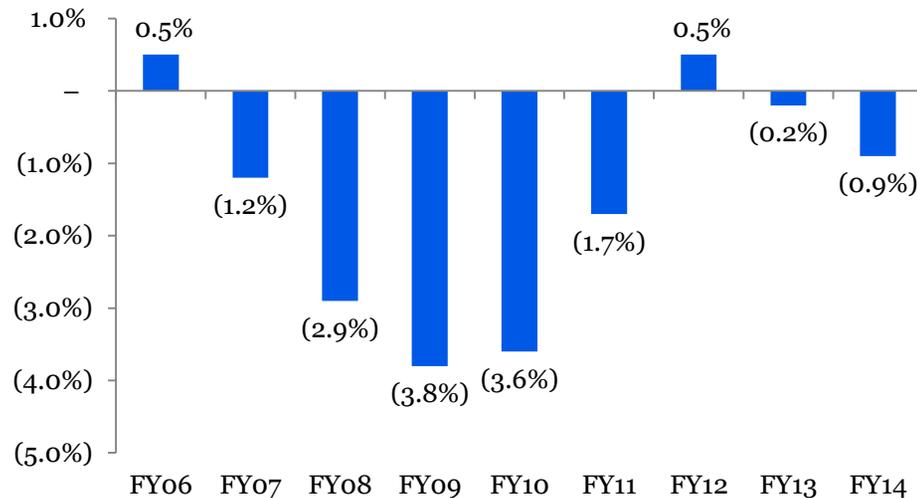

# Historical Reform Measures and Current Liquidity and Fiscal Position

# Economic Decline of Puerto Rico

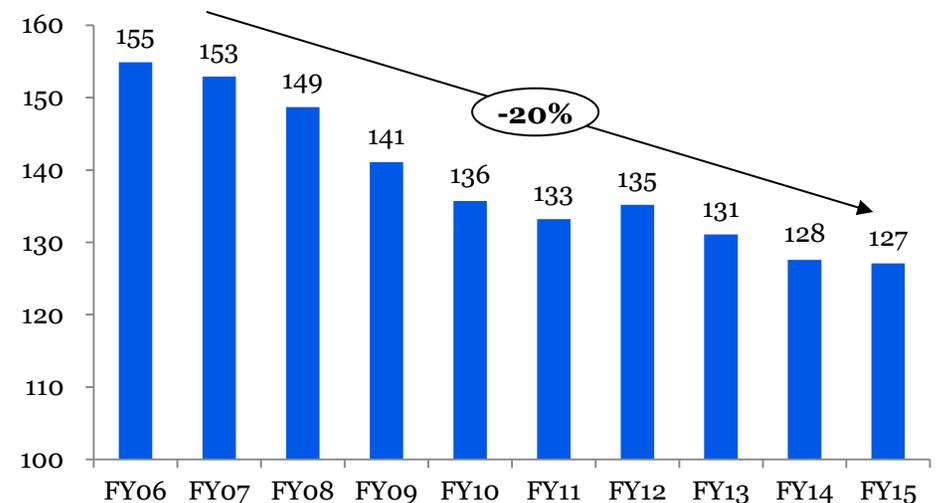

Since the expiration of Section 936 of the US Internal Revenue Code in 2006<sup>(1)</sup> and the onset of the global financial crisis in 2007, the Commonwealth has faced virtually continuous economic decline, in spite of substantial stimulus spending

- GNP growth has been negative nearly every year since FY 2007; little growth was recorded in the prior decade
- The lower rate of GNP decline since FY 2009 is due in large part to the large amount of stimulus and deficit spending injected into Puerto Rico's economy during the same period
  - For example, the Commonwealth was allocated approximately \$7.1 billion of funds through the American Recovery and Reinvestment Act ("ARRA") and, using the Puerto Rico Sales Tax Financing Corporation ("COFINA") bond proceeds from offerings in 2009 and 2010, the Commonwealth created a \$500 million "Local Stimulus Fund"
  - Furthermore, tax reform enacted in 2011 sought to jumpstart the economy by reducing individual and corporate taxes by approximately \$706 million, some of the provisions of which were later modified to deal with resulting revenue shortfalls

Real GNP Growth<sup>(2)</sup>

GDB EAI Index<sup>(2)(3)</sup>

(1) Insofar as is relevant to Puerto Rico, Section 936 of the US Internal Revenue Code exempted from US taxation certain income derived by US companies from the active conduct of a trade or business in Puerto Rico and certain Puerto Rico sourced investment income.

(2) Source: Economic Activity Index ("GDB – EAI") report for June 2015.

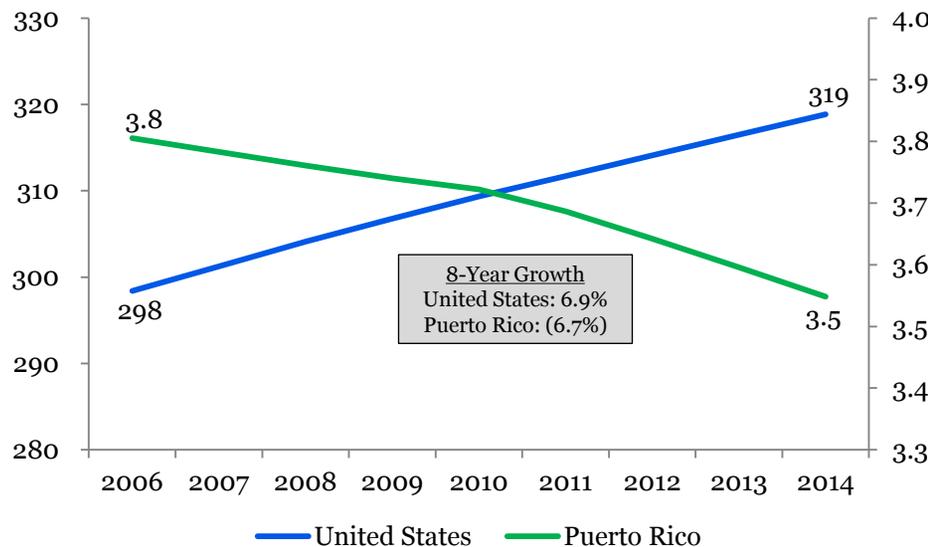

(3) Values are as of June 30 of each year. The apex in FY 2006 occurred at 158.0 in July. EAI is comprised of four indicators: total payroll employment; total electric power generation; cement sales and gas consumption. The index is highly correlated to Puerto Rico's real GNP. For additional details on the EAI, see the GDB website under "Economy."

# Deteriorating Economic Prospects & Demographic Trends

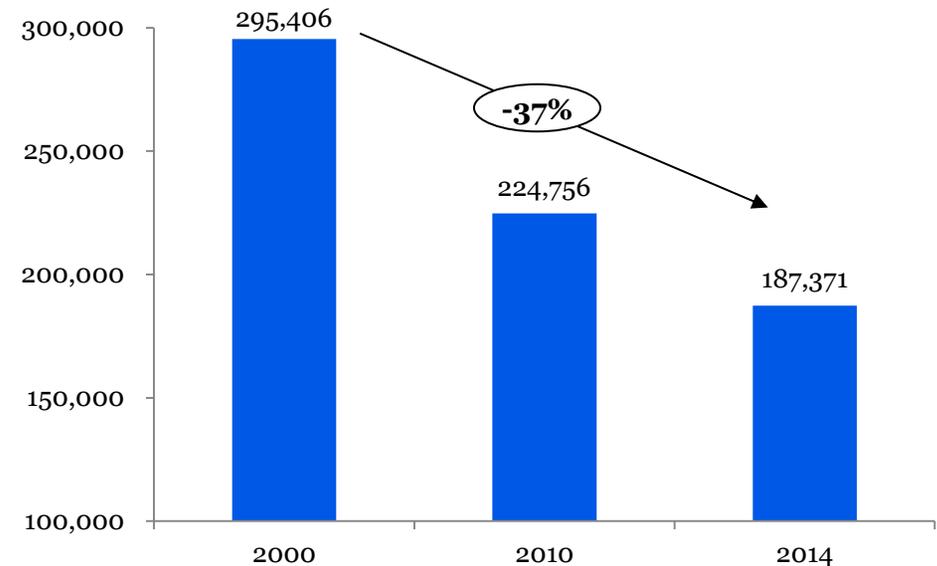

## Reduced economic activity has had a marked effect on the residents of the Commonwealth, leading to stagnating incomes and increasing outmigration to the mainland

- As multinational corporations moved out of the Commonwealth following the expiration of Section 936 and without substantial job creation, cumulative per capita income growth of 5.5%<sup>(1)</sup> from 2006 to 2013 has failed to keep pace with cumulative inflation of ~15%<sup>(2)</sup> over the same time period
- Deteriorating economic conditions have therefore led to many Puerto Ricans emigrating to the mainland
- The Commonwealth averaged net outmigration of approximately 48,000 residents per year from 2010 to 2013<sup>(3)</sup>, with 42% of emigrants stating that their primary reason for moving was job-related; in 2013, approximately 74,000 residents emigrated to the mainland<sup>(4)</sup>
- The remaining population is also becoming increasingly elderly and outside the labor force
  - Persons 60 years and older represent more than 20% of the population (the highest in the United States) and their labor participation rates range from 10.7% to 13.3%<sup>(5)</sup>; children aged five years or less have decreased from 295,406 in 2000 to approximately 187,371 in 2014, a reduction of 37%<sup>(6)</sup>

Population Data (millions)<sup>(6)</sup>

Population Under Age Five<sup>(6)</sup>

# Significant Fiscal Responsibility Measures

## The Commonwealth has repeatedly taken difficult measures to reduce its consolidated financing gaps

- The following chart represents a select subset of the various measures that the Commonwealth has taken since the onset of the economic crisis

Revenues	Expenditures	Other Fiscal Responsibility Measures
<b>2007:</b> 7% Sales and Use Tax (“SUT”) implemented ~\$1.1bn per year	<b>2010:</b> Voluntary resignation and work-day reduction programs ~\$91mm	<b>2011:</b> Gradually increase employer contribution to ERS from 9.275% to 20.525%
<b>2011:</b> Act 154-2011 institutes annually declining 4% excise tax on multinationals operating in Puerto Rico ~\$1.9bn per year	<b>2010:</b> Temporary suspension of certain laws, collective bargaining agreements and other contractual agreements ~\$187mm	<b>2011:</b> Gradually increase employer contribution to TRS from 8.5% to 19.75% per employee
<b>2011:</b> UPR <sup>(1)</sup> stabilization fee ~\$40mm per year (later repealed)	<b>2011:</b> Involuntary layoffs ~\$367mm	<b>2011:</b> Complete public-private partnership (“P3”) of PR-22
<b>2013:</b> Act 154 excise tax reset at 4% rate	<b>2013:</b> Eliminate subsidies to PRASA <sup>(2)</sup> (due to PRASA rate increase) ~\$340mm	<b>2013:</b> Complete P3 of LMM International Airport
<b>2013:</b> Petroleum products tax increase from \$3.00 to \$9.25 per barrel ~\$190mm per year	<b>2014:</b> Reduction in non-salary benefits ~\$51mm (prohibited December bonus above \$600 and liquidations of unused vacation or sick leave); government merit bonuses eliminated	<b>2013:</b> Increase employee contribution to ERS <sup>(3)</sup> from 8% to 10%; eliminate special law benefits to ERS retirees; increase retirement age
<b>2014:</b> Gross profits tax on corporations ~\$300mm per year	<b>2014:</b> Judicial and legislative budget reductions ~\$45mm	<b>2013:</b> Increase employee contribution to TRS <sup>(4)</sup> from 9% to ~13%; eliminate special law benefits to TRS retirees; increase retirement age (ruled unconstitutional in part)
<b>2014:</b> SUT charged at point of entry ~\$70mm per year	<b>2014:</b> UPR, Judicial and Municipality appropriation levels frozen from 2015-2017; CBA salary increases frozen	<b>2013:</b> Eliminate “scoop and toss” <sup>(5)</sup> of PBA <sup>(6)</sup> debt service (\$175mm in FY 2013)
<b>2015:</b> Petroleum products tax raised from \$9.25 to \$15.50 per barrel, providing an incremental ~\$170mm per year	<b>2015:</b> School transportation cost reductions and school consolidations ~\$110mm	<b>2014:</b> Eliminate “scoop and toss” <sup>(5)</sup> of GO <sup>(7)</sup> debt service (\$575mm in FY 2014)
<b>2016:</b> SUT increased from 7% to 11.5% and VAT <sup>(8)</sup> instituted; projected ~\$1.1-\$1.3bn per year	<b>2013-2015:</b> 3% annual payroll reduction	<b>2014:</b> Prohibit deficit financings by GDB

- (1) University of Puerto Rico (“UPR”).  
 (2) Puerto Rico Aqueduct and Sewer Authority (“PRASA”).  
 (3) Employees Retirement System (“ERS”).  
 (4) Teachers Retirement System (“TRS”).

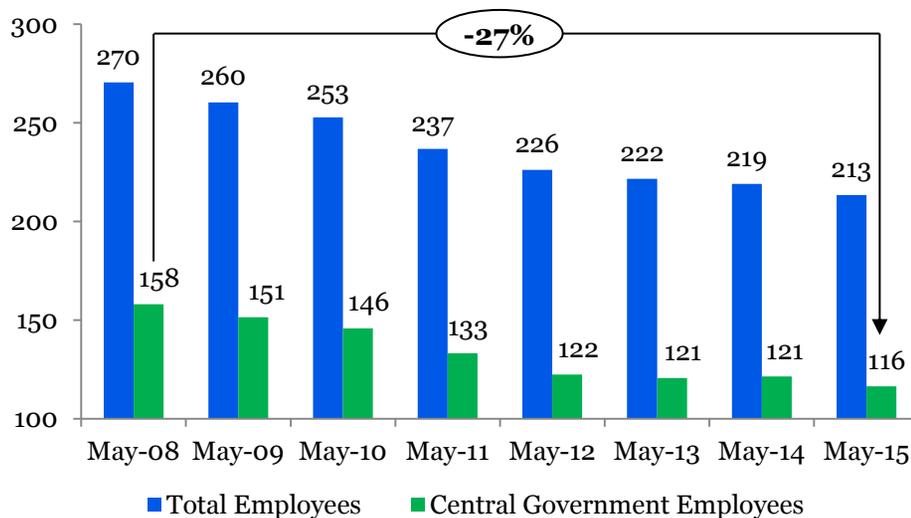

- (5) “Scoop and Toss” generally refers to the elimination of annual debt principal and interest through a refinancing with delayed payment dates.  
 (6) Public Buildings Authority (“PBA”).  
 (7) General Obligation (“GO”).  
 (8) Value Added Tax (“VAT”).

# Select Results of Historical Measures to Date

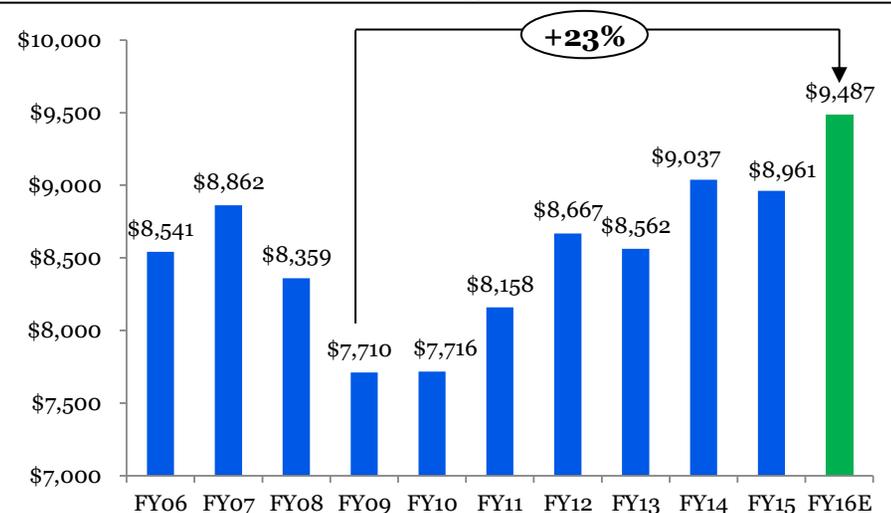

**As a result of the Commonwealth's expense reduction measures, central government employee headcount is down 27% (4.3% compounded annual decline) since 2008; further, revenue measures have allowed projected General Fund revenues for FY 2016 to grow by 23% since a recession low in FY 2009**

- Note that the General Fund revenue numbers shown below do not account for the incremental revenues that were also added at PRASA (through a rate increase), Puerto Rico Highways and Transportation Authority ("HTA") (through increased petroleum products taxes), Puerto Rico Infrastructure Financing Authority ("PRIFA") (also through petroleum products taxes) and other entities on the island which received governmental subsidies from the General Fund or GDB
- According to US Government Accountability Office, in 2012 government employment as a share of the population was 8.7% in Puerto Rico vs. 8.9% in the states<sup>(1)</sup>. Since 2012 there has been a further reduction of approximately 13,000 in the number of Puerto Rican government employees through attrition

Government Employee Headcount Reduction<sup>(2)</sup> (thousands)

General Fund Revenues<sup>(3)(4)</sup> (\$ millions)

(2) Source: Puerto Rico Statistics Institute, May 2015 Employment Report. Central government employees include Office of the Governor, Departments and Agencies, Judicial Branch and Legislative Branch as described in the report.

(3) Source: Puerto Rico Treasury website. Note that the numbers shown correspond to "Total Revenues" and not "Total Budgetary Revenues." See page 100 of the Commonwealth's Financial Information and Operating Data Report from October 30, 2014 for a historical reconciliation of "Total Revenues" to "Total Budgetary Revenues."

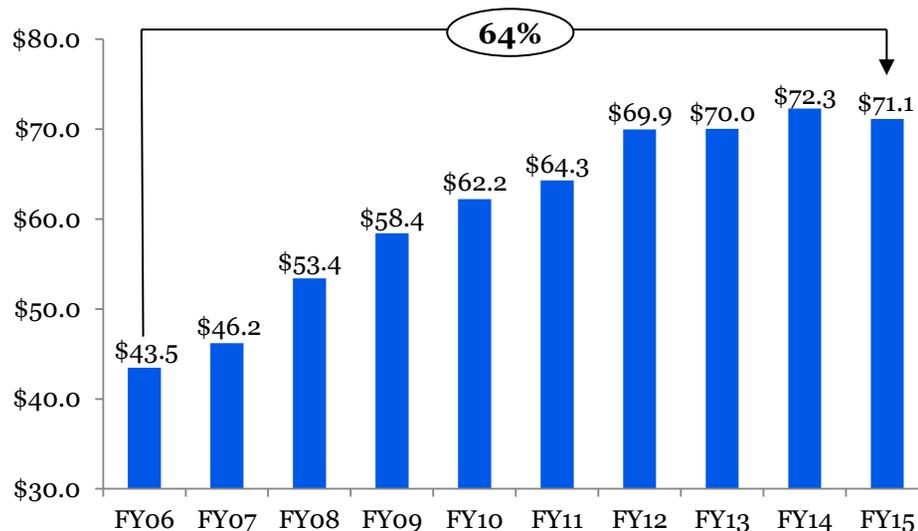

(4) FY 2016 General Fund revenue represents projections based on the work of Conway MacKenzie ("CM") and is inclusive of incremental SUT/VAT taxes projected to be collected on account of tax reform.

# Debt Accumulation

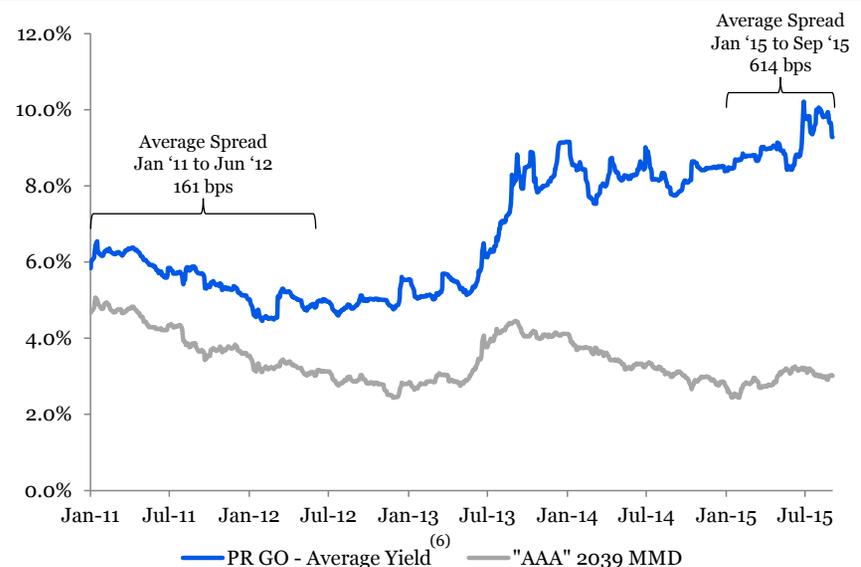

## Notwithstanding the Commonwealth's liquidity-enhancing measures, total debt has grown by approximately 64% since FY 2006

- This rising debt burden has increased total debt financing costs and has resulted in an increasing percentage of the budget being redirected from investment and essential services to debt service
- Increased financing costs are reflected in the rising yields of Puerto Rico GO bonds as compared to similar municipal bonds
  - Whereas in 2006, GO bonds with 20 years to maturity were priced to yield 4.8%, the March 2014 GOs due in 2035 (approximately 20 years to maturity) were issued to yield 8.7% and currently yield 11.3%<sup>(1)</sup>
- Given these yields, market access on sustainable terms is not currently available to the Commonwealth

Historical Public Sector Debt<sup>(2)(3)(4)</sup> (\$ billions)

Puerto Rico GO Yields vs. 2039 MMD<sup>(5)</sup>

(1) Yield on 2006 issuance from Public Improvement Bonds of 2006, Series A Offering Statement and 2014 GO current yield from Bloomberg.

(2) For more detail see the appendix for total public sector debt as of June 30, 2015. Data per GDB.

(3) Balances shown do not include the accreted value of capital appreciation bonds ("CABs"). As of July 1, 2015, the incremental accreted value of the CABs was \$2.6 billion, with another \$31.3 billion of accretion remaining.

(4) Does not include unfunded pension liabilities. Based on preliminary valuation reports as of June 30, 2014, the Employees Retirement System, Teachers Retirement System and Judiciary Retirement System ("JRS") net pension liabilities were \$30 billion, \$13 billion and \$442 million, respectively. See the May 7, 2015 Commonwealth of Puerto Rico Quarterly Report for more details.

(5) Puerto Rico GO bond valuation from Standard & Poor's (J.J. Kenny Evaluated Pricing Service). "AAA" MMD based on 2039 maturity, which was chosen as the benchmark as it is within the maturity range of the uninsured PR GO bonds included.

(6) Simple average of the historical Standard & Poor's (J.J. Kenny Evaluated Pricing Service) valuations for seven long-duration, tax-exempt, uninsured, current interest PR GO Bonds (CUSIPs: 74514LB71, 74514LB89, 74514LE86, 74514LWA1, 74514LKE6, 74514LXH5, 74514LYW1).

# Extraordinary Liquidity Measures Taken in FY 2016

Despite historical attempts to strengthen the Commonwealth's liquidity, the TSA account would have exhausted its liquidity had certain extraordinary liquidity measures not been taken for FY 2016, including:

- Funding \$400 million of its working capital needs through emergency “intra-governmental” loans funded by requiring its proprietary insurance companies to liquidate their securities portfolios<sup>(1)</sup>;
- Withholding GO set asides totaling approximately \$93 million per month;
- Requiring its insolvent pension systems to pre-fund benefit payments to retirees, which improved cash flow by approximately \$295.0 million in July 2015 and an expected \$141.0 million in each of October 2015, December 2015 and February 2016;
- Having GDB refinance the 2015 C-Series tax revenue anticipation notes (“TRANS”) (\$300 million) in July 2015, notwithstanding GDB's fragile liquidity position; and
- Delaying payment of approximately \$291.0 million in income tax refunds from the 2014 tax year
  - ↳ These refunds will not be paid in full until February 2016, at the earliest
- Moreover, the measures described on the following page do not account for any shortening of outstanding days payable to third parties that today exceed \$1.6 billion at Commonwealth agencies (excludes amounts owed by public corporations and agencies with independent treasuries)<sup>(2)</sup>
- **These extraordinary liquidity measures cannot be maintained on a long-term basis**

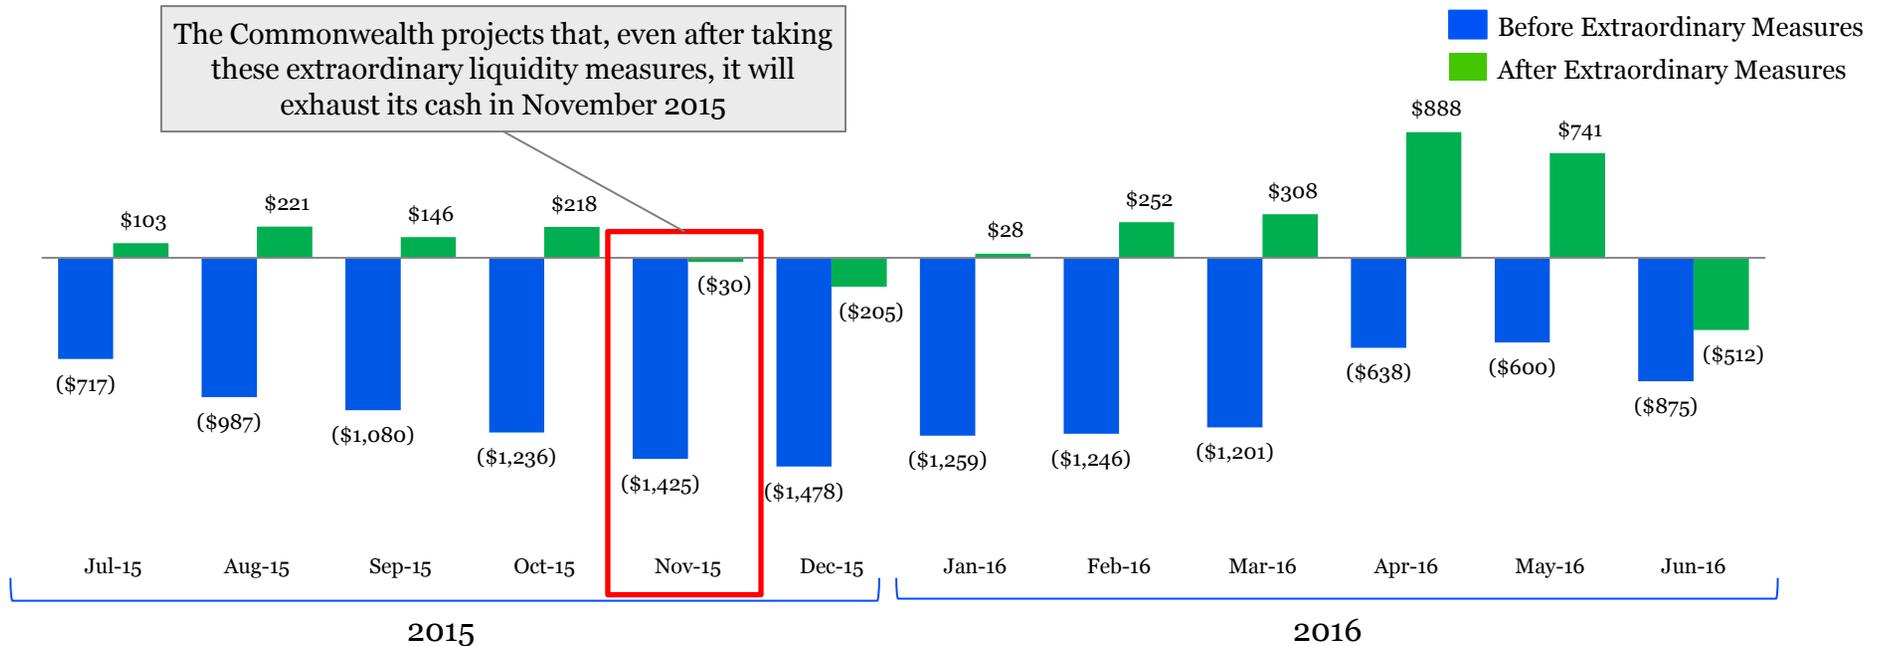

(1) Proprietary insurance companies include State Insurance Fund (“SIF”), Automobile Accidents Compensation Administration (“ACAA”) and Temporary Non-Occupational Incapacity Insurance (“SINOT”).

(2) Based on preliminary estimates subject to material revision; moreover, may not account for all payables as there is typically a substantial lag between the incurrence of an expense and that expense being recorded.

# Projected Near-Term TSA Liquidity

**Absent the Commonwealth's extraordinary and unsustainable liquidity measures described on the previous page, the TSA would have already exhausted its cash**

Projected TSA Liquidity – Ending Cash Balance <sup>(1)(2)</sup> (\$ millions)

- GDB cannot be a source of liquidity for the Commonwealth or the public corporations
  - As of May 31, 2015, GDB had \$778 million of total net liquidity, which is before any reduction for GDB's minimum liquidity requirement
  - During FY 2016, GDB has \$876 million of maturing notes, \$267 million of which are GO guaranteed (the payment of which is not included in the TSA projections above), and \$188 million of interest due

(1) Defined in the August 25, 2015 report Commonwealth of Puerto Rico: Conway MacKenzie Liquidity Update as cash in the bank and does not reflect outstanding checks, which may represent a substantial amount.

(2) Projections do not assume any working capital impact from a reduction in days payable outstanding to trade creditors or a catch-up in the payment of overdue tax refunds.

# Overview of Commonwealth Projected Financing Gaps

---

**Building on the work done in the report *Puerto Rico – A Way Forward*, updated as of July 13, 2015 (the “Krueger Report”), the Working Group developed a revised view of the future Commonwealth financing gaps (the revised view constituting the “Adjusted Estimates”)**

- As explained in the Krueger Report, which was authored by a team of former International Monetary Fund economists headed by Anne Krueger, the General Fund alone (which is the primary account associated with the TSA presented on the previous page) does not adequately capture the total financing needs of the Commonwealth
- The Working Group adopted the comprehensive approach outlined in the Krueger Report, along with many of the same key assumptions, such as an assumed baseline for real economic growth of negative 1%
- While the general approach to the financing gap projections is the same as in the Krueger Report, the Working Group conducted its own diligence and refined certain estimates based in large part on information that was not available at the time the Krueger Report was prepared
- These updates include:
  - Updated revenue projections that incorporate preliminary actual results from 2015
  - Updated component unit projections based on detailed work undertaken by the Working Group and its advisors (the Krueger Report did not have detailed individual unit projections)
  - Revised estimates of budgeted expenses and the resultant impact of Act 66
  - Revised capital expenditure estimates

# Overview of Commonwealth Projected Financing Gaps

---

- In addition to these updates, the Adjusted Estimates include two changes to the approach taken in the Krueger Report:
  - HTA is now included in the projections, due to its reliance on taxes collected by the Commonwealth and the Commonwealth's support of HTA historically through the assignment of new revenue sources and the provision of over \$2 billion of loans from GDB
  - Rather than showing estimates of retirement system shortfalls once they were projected to take place, the FEGP assumes the Commonwealth makes the additional uniform contribution (the "AUC") required by Act 3-2013 and Act 160-2013 to prevent full asset depletion. Both the Krueger Report and the Adjusted Estimates show the financing gap effectively assuming no interruption of current benefits<sup>(1)</sup>
- Additional details on the variances of the Adjusted Estimates to the Krueger Report are available in the appendix

---

(1) See the appendix for additional details on assumed asset balances in the retirement systems.

# Projected Financing Gaps Based on Adjusted Estimates

The Working Group's revised projections indicate that the Commonwealth as a whole will face significant financing gaps for at least the next five years, absent additional measures

Central Government Outlook (\$ millions)	2016P	2017P	2018P	2019P	2020P	Total
<b>Revenues</b>						
General Fund and Other Select Revenues <sup>(1)</sup>	\$8,503	\$8,519	\$8,561	\$8,604	\$8,648	\$42,835

Inflows from Other Entities <sup>(18)</sup>	105	–	–	–	–	105
<b>Identified Financing Sources (Uses)</b>	<b>(433)</b>	<b>(1,327)</b>	<b>(501)</b>	<b>(501)</b>	<b>(501)</b>	<b>(3,264)</b>
<b>Total Estimated Financing Gap before Measures</b>	<b>(\$4,075)</b>	<b>(\$4,386)</b>	<b>(\$4,670)</b>	<b>(\$7,437)</b>	<b>(\$7,217)</b>	<b>(\$27,786)</b>
<i>Memo: Debt Service as a % of Total Revenue ex. Federal Transfers<sup>(19)</sup></i>	42%	35%	32%	37%	33%	36%

Note: Revenues do not include any incremental tax revenues attributable to the increased SUT or transition to the VAT which would reduce the projected financing gap by \$6.350 billion (See page 56). For footnotes and additional details on the projections included herein, please see the appendix.

---

# Fiscal and Economic Growth Measures

# Scope & Process of the Fiscal and Economic Growth Plan

---

**In order to address the challenges facing the Commonwealth, Governor García Padilla tasked the Working Group to develop a Fiscal and Economic Growth Plan**

- The creation of the Working Group was in direct response to the Krueger Report regarding the fiscal and economic situation of the Commonwealth and the sustainability of its debt
- The Governor's executive order mandates that the Working Group evaluate the measures outlined in the Krueger Report and ultimately design a plan to address short and long-term fiscal challenges facing the Commonwealth by recommending measures to:
  - Address financing gaps and the debt load;
  - Ensure budget compliance;
  - Provide greater financial transparency; and
  - Carry out structural reforms necessary to restore economic competitiveness and growth
- The Working Group, in conjunction with its advisors, conducted due diligence on various Commonwealth funds, agencies and public corporations that are supported by taxes and appropriations and contributed to the fiscal deficits identified in the Krueger Report, in order to create a holistic projection of Commonwealth finances
- After identifying and estimating key contributors to historical and future Commonwealth-wide deficits, the Working Group also examined various measures outlined on the following pages that will help address the financing gaps identified in the Krueger Report

# FEGP Measures

---

*“The situation is acute in the face of faltering economic activity, faltering fiscal and debt sustainability, and faltering policy credibility. A comprehensive program that tackles all three has a better chance of success than a partial approach, and the advantage of sharing the costs and benefits of reform across government, workers, businesses, and creditors.” –The Krueger Report p.26*

## 1. Economic Growth and Structural Reform

- 1.1 Stimulate Employment and Labor Force Participation
- 1.2 Diversify Fuel Base and Stabilize Energy Rates
- 1.3 Implement Pro-Growth Corporate Tax Regime
- 1.4 Reduce Costs and Improve Ease of Doing Business
- 1.5 Invest in Strategic Infrastructure

## 2. Fiscal Stability

### Revenue Enhancing Measures

- 2.1 Complete Transition to VAT
- 2.2 Stabilize Corporate Tax Revenue Base
- 2.3 Improve Tax Administration and Enforcement

### Expense Reduction Measures

- 2.4 Reduce Operating Costs
- 2.5 Cut Governmental Subsidies
- 2.6 Right-Size Department of Education
- 2.7 Control Health Care Costs
- 2.8 Leverage P3s to Deliver Quality and Cost-Efficient Services

## 3. Institutional Reform and Transparency

- 3.1 Install New Accounting and Financial Systems
- 3.2 Establish Centralized Treasury Functions
- 3.3 Improve Fiscal and Economic Decision-Making
- 3.4 Implement New Budgetary Rules
- 3.5 Institute Control Board for Policy Continuity and Compliance

# Economic Growth and Structural Reform

*“Restoring growth requires restoring competitiveness. Key here is local and federal action to lower labor costs gradually and encourage employment (minimum wage, labor laws, and welfare reform), and to cut the very high cost of electricity and transportation (Jones Act). Local laws that raise input costs should be liberalized and obstacles to the ease of doing business removed.” – The Krueger Report p. 1*

## Economic Growth and Structural Measures

Target Date

### 1.1 Stimulate Employment and Labor Force Participation

**Only 40% of Puerto Rico’s adult population (vs. 63% in the US) is employed or looking for work.** A significant portion of the population is either receiving welfare, informally employed or both. The Commonwealth must **adopt pro-growth labor market policies, reform welfare programs and determine policy with respect to its minimum wage**

#### Private Sector Labor Reform

January 2016

- Enact legislation to reform current labor laws to incentivize growth and boost labor participation
  - Establish a uniform work day and enable employers to provide flexible work week schedule
    - 8-hour work day based on calendar days, not consecutive 24 hour periods
    - Provide option for overtime to be calculated based on hours worked in excess of 40 hours per week, not in excess of 8 hours per day
  - Incentivize businesses, including small and medium enterprises (“SMEs”), to expand job opportunities
    - Ease December bonus payment waiver process
    - To incentivize youth employment and reverse emigration trends, make discretionary December bonus payment to employees 25 and under
    - Modify mandatory vacation days for all new hires based on sliding scale tiered off an employee’s years of employment
    - Extend employment probation period to one year

# Economic Growth and Structural Reform

## Economic Growth and Structural Measures

## Target Date

### 1.1 Stimulate Employment and Labor Force Participation (cont.)

- Reform mandatory severance; allow performance-based retention
  - Apply Act 80-1976 only to “non-exempt” employees
  - Limit mandatory severance pay at six months; exclude non-cash benefits from severance calculations
  - Allow businesses to retain employees based on performance in the event of a downsizing or reorganization of operations
- Simplify and make uniform other labor market regulations, including establishing a one-year uniform statute of limitations for labor claims
- Create maternal benefits fund, funded by employer premiums, to reduce incentives for discrimination and increase labor participation while maintaining current maternity benefit level

January 2016

### Welfare Reform and Stimulating Work

- Establish an Earned Income Tax Credit (“EITC”)
  - Establish an EITC that, like the federal EITC, targets families with children, headed by working age persons, to stimulate employment among low-wage workers, reduce informal economy activities, bring families into the tax system and offset sales tax regressivity
    - ❖ Cost after full implementation will be ~\$150 million per year
    - ❖ Former Commonwealth EITC program (2006-2014) did not differentiate among claimants by filing status, presence of dependents or age of the tax filers
- Reform Nutritional Assistance Program (“NAP”) Benefits
  - Request US Department of Agriculture (“USDA”) to extend gross income exception for the receipt of NAP benefits from 12 to 18 months to allow more time for employees to experience salary and benefits increases that outweigh loss of NAP benefits
  - Modify NAP income thresholds for the Commonwealth so that program participants experience a more gradual and income-targeted reduction in NAP benefits when entering the workforce to eliminate the current cliff effect on benefit reduction

March 2016

March 2016

# Economic Growth and Structural Reform

## Economic Growth and Structural Measures

## Target Date

### 1.1 Stimulate Employment and Labor Force Participation (cont.)

- Public Housing and Section 8
  - Apply to US Department of Housing and Urban Development (“HUD”)’s “Moving to Work” program to receive waivers of rules that govern public housing and federal Section 8 voucher program
    - ❖ Program’s goal is to give incentives to families with children, where the head of household is working, seeking work, or is preparing for work to obtain employment, becomes economically self-sufficient and increase housing choices for low income families
      - After receiving waiver, local Housing Department to develop rent structures that allow residents to increase their earnings through work without penalty
  - Apply to HUD’s “Jobs Plus Pilot Program”
    - ❖ Program incentivizes employment through income-disregards for working families, and provides a set of services designed to support work including employer linkages, job placement and counseling, educational advancement, and financial counseling
  
- Integrate Childcare Services
  - Integrate Family Department’s child care and Head Start programs with the Puerto Rico Department of Education’s Pre-K program in local public schools in order to reduce transportation costs for working families with multiple children and provide such families with full day childcare options
    - ❖ Cost of program under evaluation

### Minimum Wage

- To promote the hiring of young workers, request Congress to grant a 10-year waiver from future minimum wage increases for workers aged 25 and younger. This increase to the minimum wage would apply to any individual worker after 2 years
  
- Grant the petition by the Commonwealth to exempt Puerto Rico from the US Department of Labor proposal to increase the salary level for required exemption under the Fair Labor Standards Act (“FLSA”) referred to as “EAP” or “white collar” exception, which would increase the salary threshold for exempt employees that are full time salaried employees to \$50,440 annually

# Economic Growth and Structural Reform

## Economic Growth and Structural Measures

## Target Date

### 1.2 Diversify Fuel Base and Stabilize Energy Rates

Lack of fuel diversification, mismanagement and lack of energy policy continuity have resulted in **high energy costs, eroding the Commonwealth's competitiveness** and increasing the cost of doing business

- Complete restructuring of Puerto Rico Electric Power Authority's ("PREPA") capital structure and operations to produce cash flow relief during next five years to invest in necessary infrastructure and stabilize rates To be determined

  - ❖ On September 1, 2015, PREPA announced that it had reached an agreement in principle with the Ad Hoc Group of PREPA bondholders – comprised of traditional municipal bond investors and hedge funds that hold approximately 35% of PREPA's outstanding bonds – regarding the economic terms of a restructuring of a significant portion of PREPA's bond debt. PREPA's agreement with the Ad Hoc Group marks PREPA's first agreement with a significant financial stakeholder regarding the substantive terms of its financial transformation. PREPA will continue negotiating with its financial guaranty bond insurers and revolving fuel line lenders, with the goal of reaching an agreement on a consensual recovery plan among all of its major financial stakeholders
  
- Issue request for proposal ("RFP") to third-party investors to upgrade existing generation capacity and build new, more efficient generation plants, allowing PREPA to transition into a transmission and distribution company 2016 <sup>(1)</sup>
  
- Depoliticize PREPA by attracting professional external management and directors 2016 <sup>(1)</sup>
  
- PREPA to invest more than \$2 billion over the next five years to upgrade vital generation, transmission and distribution infrastructure 2015-2020

(1) Contingent on timing of PREPA's restructuring.

# Economic Growth and Structural Reform

## Economic Growth and Structural Measures

## Target Date

### 1.3 Implement Pro-Growth Corporate Tax Regime

The Commonwealth's current corporate tax regime is too complex, distorts economic choices and produces horizontal inequities. Puerto Rico must **institute a pro-growth tax regime** applicable to all companies doing business on the island that **lowers nominal tax rates and eliminates loopholes and unnecessary complexity**

- Enact legislation to amend Puerto Rico's Internal Revenue Code to implement flatter, lower-rate corporate tax regime for both new and existing companies March 2016
  - Reduce nominal corporate tax rates
  - Eliminate inefficient corporate deductions and tax credits; eliminate or reduce alternative minimum tax
    - ❖ Simplified corporate tax regime would reduce unnecessary compliance burdens on entrepreneurs
  
- Enact legislation, after dialogue with existing multinationals, to retain and attract foreign direct investment March 2016
  - Legislation would amend Act 154-2011 to extend the 4% excise tax for an additional 5-year period to stabilize the General Fund's revenue base<sup>(1)</sup>
  - With respect to foreign multinationals, legislation would also amend Act 73-2008 and be applicable to new companies coming to Puerto Rico, existing companies wishing to convert to new tax regime and all firms after the expiration of their current tax grants
  - New regime would seek to substitute Act 154-2011 excise tax and its revenues without increasing overall tax liability to existing companies, including foreign companies that currently do not credit the excise tax against federal income

(1) For Act 154 extension 5-year revenue projections, please refer to measure 2.2 of the Fiscal Stability section.

# Economic Growth and Structural Reform

---

## Economic Growth and Structural Measures

## Target Date

### 1.3 Implement Pro-Growth Corporate Tax Regime (cont.)

- Request Congress to provide Puerto Rico with tax treatment that encourages US investment on the island, such as:
  - Section 933A: Amend US Internal Revenue Code to add new Section 933A to permit US-owned businesses in Puerto Rico to elect to be treated as US domestic corporations
  - Economic Activity Tax Credit: Enact an economic activity tax credit for US investment in Puerto Rico designed as a targeted, cost-efficient version of former Section 936 of the US Internal Revenue Code
  - Base Erosion: In the event the US moves towards a territorial taxation system, exempt Puerto Rico from base erosion and/or minimum tax measures

November 2015

# Economic Growth and Structural Reform

## Economic Growth and Structural Measures

## Target Date

### 1.4 Reduce Costs and Improve Ease of Doing Business

**Puerto Rico has been losing competitiveness** as measured by global reports produced by the World Economic Forum and the World Bank. To jumpstart its economy, **Puerto Rico must be equipped with a business-friendly environment that is conducive to sustained economic growth**

- Centralize and streamline permitting process
  - Submit legislation to: January 2016
    - Centralize all permit application processes in the Office of Management of Permits (“OGPe”), providing a single access point and electronic permit interface for all agencies and municipalities
    - Where a federal environmental review procedure is required, integrate concurrent local agency review and make the federal record of decision (“ROD”) binding on local agency ruling to lower costs and avoid inconsistent administrative rulings
    - Provide for a 7-day agency response period for “Categorical Exclusions” (e.g. minor lot designation variations for low impact environmental construction works); applications deemed granted if agency has not ruled on permit during said period
    - Require municipalities to adopt simplified uniform general permitting regulations (“*Reglamento Conjunto*”)
  - Issue Executive Order to expedite planning, permitting and environmental review procedure for high-priority projects, including high-impact infrastructure projects outlined in the FEGP November 2015
  - Consolidate Environmental Quality Board, Solid Waste Authority and Natural and Environmental Resources Department in order to simplify and streamline the environmental review process April 2016
  - Adopt a joint general construction permit and expedited application procedure for “low impact” construction projects April 2016

# Economic Growth and Structural Reform

---

## Economic Growth and Structural Measures

## Target Date

### 1.4 Reduce Costs and Improve Ease of Doing Business (cont.)

- |   |               |
|---|---------------|
| <ul style="list-style-type: none"> <li>▪ Modernize property registry               <ul style="list-style-type: none"> <li>- Pass House Bill No. 2479 to implement 100% digital, electronic and paperless property registry platform                   <ul style="list-style-type: none"> <li>❖ Platform expected to be effective upon legislative approval</li> </ul> </li> </ul> </li> </ul> | November 2015 |

# Economic Growth and Structural Reform

## Economic Growth and Structural Measures

## Target Date

### 1.5 Invest in Strategic Infrastructure

**The Commonwealth's infrastructure assets (ports, roads, bridges) are in need of substantial capital investments** due to limited financial resources and historically insufficient maintenance. In order to grow the economy, the Commonwealth must **increase spending on capital expenditures** to strengthen its infrastructure system and allow it to continue to serve as a pillar of economic growth. **Given the tight fiscal situation, the Commonwealth should leverage P3s to help achieve its capital expenditure goals**

- Central government to use cash from operations to invest approximately \$3.3 billion<sup>(1)</sup> during the five-year growth and adjustment period to improve infrastructure, boost aggregate demand and implement structural and fiscal measures 2015-2020  
(annual targets)

  - Government to begin budgeting for capital expenditures as part of General Fund budget
  - Capital expenditures (“capex”) program designed to leverage federal matching funds, prioritize projects with economic impact and provide adequate maintenance to public infrastructure, including buildings, roads and bridges
    - Total investment including federal matching funds, amount to ~\$7.7 billion
- In addition to directly funding its capital improvement program, the Commonwealth will seek to leverage P3s to build, maintain and operate new and legacy infrastructure, including electricity generation plants and transportation assets 2015-2020  
(annual targets)
- Strategic infrastructure projects (financed by government, federal and/or private funds) include: 2015-2020  
(annual targets)

  - Roads: Extension of Northwest Highway Corridor, PR-10
  - Airports and Ports: Upgrade Piers 1 and 4, Terminal, Roadway and Taxiways in Aguadilla Airport, Port of the Americas, Dry Dock, Army Terminal, Maintenance Dredging in San Juan Bay
  - Health: Science District (including cost to complete Comprehensive Cancer Center)
  - Strategic: Roosevelt Roads; investments in other strategic sectors (e.g. aerospace)
  - Other: Flood control projects, necessary rehabilitation and maintenance of roads and other public assets

(1) FEGP projections contemplate this investment in maintenance and strategic capex.

# Economic Growth and Structural Reform

---

## Economic Growth and Structural Measures

## Target Date

### 1.5 Invest in Strategic Infrastructure (cont.)

- Independent public enterprises, such as PREPA and PRASA, will separately undertake significant capex programs
  - PREPA plans to invest more than \$2 billion over the next five years to upgrade vital generation, transmission and distribution infrastructure, including the Aguirre Offshore Gas Port (“AOGP”)
    - ❖ PREPA restructuring process expected to release sufficient resources to undertake capex program
    - ❖ PREPA submitted a loan application to the US Department of Energy (“DOE”) 1703 Program to finance a portion of AOGP
  - PRASA also contemplates financing approximately \$1.4 billion in capex during the same period for water/waste water infrastructure renewal and replacement, water loss control and technology, among others
- Leverage federal resources through the Build America Transportation Investment Center on transportation related infrastructure projects and P3 proposals

2015-2020  
(annual targets)

# Fiscal Stability – Revenue Enhancing Measures

“Given looming revenue and spending pressures, eliminating the fiscal deficit will take substantial measures. Reforms should aim more at broadening tax bases than raising rates, and at targeted expenditure reduction rather than across-the-board cuts. But even a major fiscal effort leaves large residual financing gaps that will need to be bridged with debt relief.” –the Krueger Report p.19

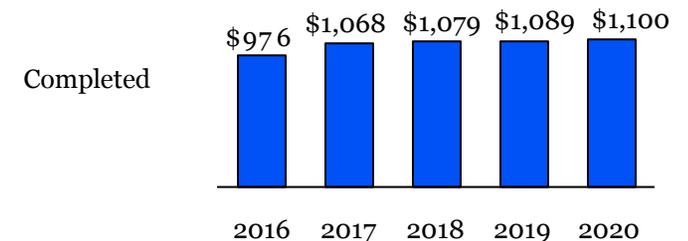

Revenue Enhancing Measures	Target Date	Estimated Incremental Impact FYs (\$ millions)
----------------------------	-------------	--

## 2.1 Complete Transition to VAT

In order to decrease tax evasion and increase the revenue capture rate, the Commonwealth must place greater reliance in consumption taxes and move towards VAT. **On May 29, 2015, the Government enacted Act 72-2015, which increases the SUT rate from 7.0% to 11.5%, expands the tax base by taxing certain business to business (“B2B”) services and provides for a VAT to substitute the Central Government’s portion of the SUT**

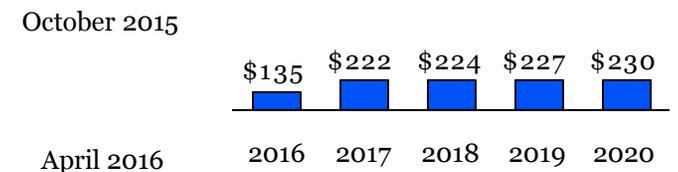

### Increase SUT Rate

- Starting July 2015, transactions that were subject to the 7% SUT are now subject to an 11.5% SUT, with the entire 4.5% increase going to the Central Government<sup>(1)</sup>

### Taxing B2B Services and Transitioning to VAT System (Incremental to SUT Rate)<sup>(1)</sup>

- Starting October 2015, B2B transactions that are currently taxable will be subject to an 11.5% SUT; B2B transactions and professional services that were previously exempt from the SUT will be subject to a 4% SUT
- Starting April 2016, all transactions subject to the SUT will be subject to a new VAT of 10.5% plus a 1% municipal SUT

(1) Numbers shown are the estimated benefit to the General Fund.

# Fiscal Stability – Revenue Enhancing Measures

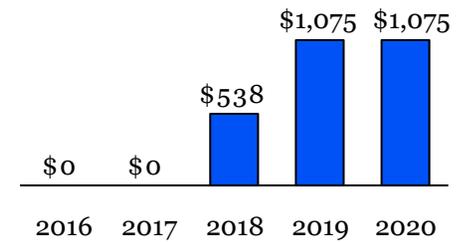

Revenue Enhancing Measures	Target Date	Estimated Incremental Impact FYs (\$ millions)
----------------------------	-------------	--

## 2.2 Stabilize Corporate Tax Revenue Base

**The Commonwealth is currently highly dependent on Act 154-2011 excise tax receipts** (approximately 20% of general fund revenues). The 4% excise tax is due to be replaced by a “Modified Source Income Rule” tax in December 2017 (FY 2018) and an extension of the 4% tax rate is necessary to ensure revenue certainty during fiscal and economic adjustment period

- Extend Act 154-2011 4% excise tax for an additional 5-year period as existing multinationals transition to a new corporate tax regime
- Amend, after consultation with existing multinationals, the Internal Revenue Code and Act 73-2008, to establish a new corporate tax regime that substitutes the Act 154-2011 excise tax and its revenues without increasing overall tax liability to existing companies

March 2016

Note: Incremental impact vs. Krueger Report’s “Loss of Act 154” downside risk as modified by Adjusted Estimates

# Fiscal Stability – Revenue Enhancing Measures

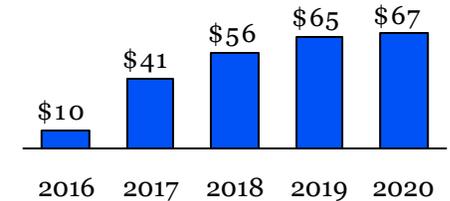

Revenue Enhancing Measures	Target Date	Estimated Incremental Impact FYs (\$ millions)
----------------------------	-------------	--

## 2.3 Improve Tax Administration and Enforcement

**The Commonwealth lacks a robust, modern and effective tax administration**, resulting in significant tax evasion and high taxpayer compliance and administrative costs

- Leverage technology and training in order to increase capture rates and improve tax administration and enforcement, including:

2016-2020  
(annual targets)

- Improve Integrated Merchant Portal System (“PICO”)
- Implement Automated System for Customs Data (“ASYCUDA”)
- Expand alternative delivery and payment channels’ capabilities
- Transform Collection Centers into Integrated Service Centers
- Joint-ventures with Municipalities for SUT oversight
- Implement performance management, develop work plans and create Professional Development Institute

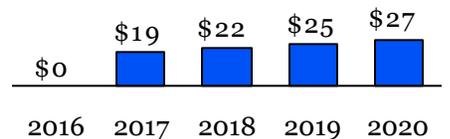

- Restrict use of tax amnesties and closing agreements to increase revenue certainty and reduce tax evasion

June 2016

- Tackle widespread use of illegal video lottery machines that erode Puerto Rico’s tax base by implementing and enforcing tax on, and regulating, video lottery games<sup>(1)</sup>

March 2016

Note: All impact estimates are net of investments.

(1) Net of transfers as required by law.

# Fiscal Stability – Expense Reduction Measures

Expense Reduction Measures	Target Date	Estimated Incremental Impact FYs (\$ millions)
----------------------------	-------------	--

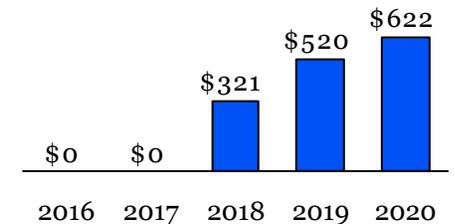

## 2.4 Reduce Operating Costs

Despite significant efforts to **reduce central government expenses** through headcount attrition, freezing formula-based appropriations, service costs and collective bargaining agreements, among other measures, the Commonwealth’s upcoming fiscal challenges, including unfunded retirement systems and increasing health care costs, **will require further expense cuts in governmental subsidies, a gradual reduction in payroll expenses and the implementation of additional operational efficiencies**

### Act 66

- Extend until FY 2021 Act 66-2014’s freeze of new hires, formula-based appropriations, service costs, increase in salaries and collective bargaining agreements<sup>(1)</sup>

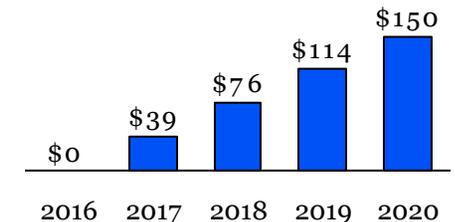

December 2015

### Human Resources

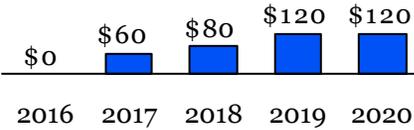

- Reduce payroll costs by implementing a 2% annual attrition target<sup>(1)(2)</sup>
  - To achieve attrition target, the Office of Management and Budget (“OMB”) may offer early retirement window to selected public sector employees
  - Commonwealth may use a portion of the proceeds of P3 initiatives to incentivize voluntary retirement

2016-2020  
(annual targets)

(1) Impact does not include the negative effect on Additional Uniform Contribution to the public pension systems.  
 (2) Totals excludes Puerto Rico Department of Education (“PRDE”). Attrition target with respect to PRDE is included in Section 2.6 hereto.

## 2.4 Reduce Operating Costs (cont.)

### Teacher’s Retirement System

June 2016

- Supreme Court opinion ruled that certain sections of Act 160 can only be applied prospectively to newly hired teachers. Further changes to the TRS are required to ensure the payment of benefits for years to come. Accordingly, TRS is working closely with actuaries towards a reformed proposal that ensures payment of benefits to existing retirees while passing constitutional scrutiny and that considers increases to employee contributions and/or modifications to special law benefits

# Fiscal Stability – Expense Reduction Measures

Expense Reduction Measures	Target Date	Estimated Incremental Impact FYs (\$ millions)
----------------------------	-------------	--

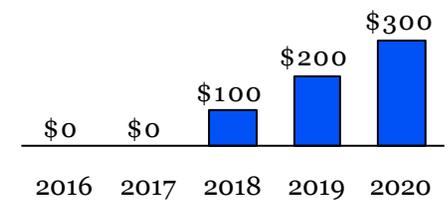

## 2.5 Cut Government Subsidies

The central government's precarious fiscal situation is exacerbated by the **sizable appropriations to independent government entities including municipalities and UPR**. For FY 2015, the government allocated almost 18% of its General Funds in appropriations to independent entities while significantly reducing the budget for the central government

### Municipalities

- Enact legislation to, beginning FY 2018, gradually adjust subsidies provided to municipalities by the central government, while empowering municipalities with the proper legal, administrative and operational tools for them to offset such decrease
  - ❖ Municipalities may present revenue generation and expense reduction initiatives, that may include changes to municipal license fees, modernization of property tax regime and municipal consolidations, among others
  - ❖ Central government to commission a study to provide analysis of, and recommendations with respect to, the relevant alternatives

March 2016

# Fiscal Stability – Expense Reduction Measures

Expense Reduction Measures	Target Date	Estimated Incremental Impact FYs (\$ millions)
----------------------------	-------------	--

## 2.6 Right-Size Department of Education

Since 1980, enrollment at public schools has declined 41% and, due to demographic trends, it is expected to fall an additional 25% (~317,000 students) by 2020. This decline has led to a reduction in school utilization and a decrease in the student to teacher ratio to 12:1 (US average is 16:1). The Puerto Rico Department of Education has made significant progress during the last two years by consolidating 135 schools and reducing the number of temporary teachers by more than 1,000

- Consolidate public schools based on specific parameters such as enrollment, school utilization and distance to adjust PRDE’s facilities to current demographic trends and improve student-to-teacher ratio for both underutilized and overcrowded schools

  - ❖ The PRDE has made significant progress over the last two years in adjusting its human capital and physical infrastructure to its fiscal and demographic reality. As it continues to right-size its resources, the PRDE will ultimately position itself to deliver high quality education with well compensated teachers
  
- Reduce PRDE’s payroll through 2% attrition<sup>(1)</sup>
  
- Complete remaining phases of PRDE’s ongoing restructuring plan, which requires overhauling the PRDE’s management and operations and reducing expenditures on select private services
  
- Consider selected asset sales, including the Commonwealth’s real estate asset portfolio, to finance retirement windows for teachers and/or capitalize severely underfunded Teachers Retirement System

2016-2020  
Estimated impact should be determined by March 2016

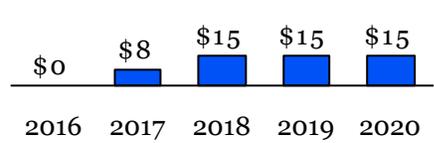

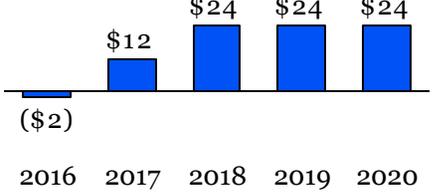

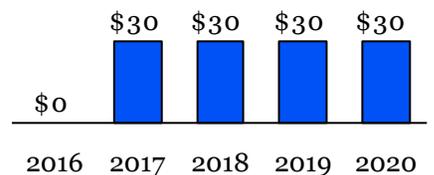

(1) Attrition calculated net of impact attrition measure in Section 2.4 hereto; impact does not include the negative effect of Additional Uniform Contribution to Teachers Retirement System.

# Fiscal Stability – Expense Reduction Measures

Expense Reduction Measures	Target Date	Estimated Incremental Impact FYs (\$ millions)
----------------------------	-------------	--

## 2.7 Control Health Care Costs

**The Commonwealth’s public health care plan covers approximately 1.6 million beneficiaries** (all but 180,000 of which are not covered by Medicaid) and is financed by a combination of federal and local funds.<sup>(1)</sup> Puerto Rico ranks #14 nationally in terms of total Medicaid enrollment and #1 as a percentage of population enrolled (48%). While the Commonwealth **is subject to a federal spending cap that limits federal dollars for Medicaid to approximately \$260 million (excluding \$150 million for the Children’s Health Insurance Program “CHIP”), there is no cap for US states. Puerto Rico also faces a “health care cliff,” currently estimated to grow to \$1.7 billion dollars by 2020, upon the exhaustion of Affordable Care Act funding in FY 2018**

<ul style="list-style-type: none"> <li>Implement “STAR”-like<sup>(3)</sup> rating system and establish a provider payment scale based on performance</li> </ul>	October 2015	 <table border="1"> <tr><th>FY</th><th>Impact (\$ millions)</th></tr> <tr><td>2016</td><td>\$0</td></tr> <tr><td>2017</td><td>\$8</td></tr> <tr><td>2018</td><td>\$15</td></tr> <tr><td>2019</td><td>\$15</td></tr> <tr><td>2020</td><td>\$15</td></tr> </table>	FY	Impact (\$ millions)	2016	\$0	2017	\$8	2018	\$15	2019	\$15	2020	\$15

# Fiscal Stability – Expense Reduction Measures

## Expense Reduction Measures

## Target Date

### 2.8 Leverage P3s to Deliver Quality and Cost-Efficient Services

The need for **proper infrastructure construction and maintenance, necessary for economic growth, can be met by leveraging public private partnerships**. Recent positive experience with the LMM Airport and PR-22 Highway demonstrate that P3s are a viable model and an effective tool to rehabilitate and develop necessary infrastructure, reduce operational costs and improve governmental services for the Commonwealth

- Concession remaining toll roads, including PR-20, PR-52 and PR-66 in consultation with US Department of Transportation (estimated impact subject to terms of concession)

  - Improve, intra-Island connectivity, road and bridge quality, and travel safety. Continuous investment in and maintenance of the roads would be mandatory as set forth in a Concession Agreement
  - Concessions would help transform HTA into a contract administrator and limit its construction role
- Merge Public Building Authority and Office for the Improvements of Public Schools (“OMEP”) (estimated impact subject to terms of concession)

  - Transform PBA into a more efficient and effective public corporation; consider transferring the construction function to (“PRIFA”) to avoid duplication of functions
- P3 maritime transport and bus system operations (estimated impact subject to terms of concession)

  - Maritime: 5-year minimum concession agreement for the operation and maintenance of the public maritime transportation services
  - AMA: currently evaluating possible transfer of operations to municipalities and potential P3 transactions
- Evaluate potential concessions for ports and airport operations or facilities, and work with the Federal Aviation Administration (“FAA”) to consolidate underutilized or geographically unnecessary airports (estimated impact subject to terms of concession)
- Identify and pursue additional P3 opportunities

# Institutional Reform and Transparency

*“The legacy of budgetary laxity, non-transparency, and unreliable/dated statistics must be overcome if the reform program is to work and command credibility. The priorities include a rolling 5-year budgetary plan approved by the legislature, legislative rules to limit changes to the plan, an independent fiscal oversight board to advise on the budget and control its implementation, and strengthening the quality and timeliness of economic data.” –The Krueger Report p.22*

## Institutional Reform and Transparency Measures

## Target Date

### 3.1 Install New Accounting and Financial Systems

The central government’s financial and payroll systems are obsolete and can not communicate with the systems of principal agencies, such as the PRDE and the Health Department. Lack of integration of agencies under the same platform hinders the ability to timely monitor expenses, complete annual audits and publish accounting financial statements

- Implement new financial/accounting and payroll system that unifies the patchwork of governmental platforms, which affect the government’s ability to properly monitor its fiscal situation and result in material delays in the preparation of financial information July 2017
  - Contract system provider (implementation schedule is expected to be approximately 18 to 24 months) November 2015
  - Requires an approximate investment of at least \$25 million to \$40 million

### 3.2 Establish Centralized Single Treasury Function

The Commonwealth currently has a highly fragmented treasury system that places weak emphasis on ensuring fiscal and financial controls and provides little visibility of the Government’s consolidated financial position. The centralization of treasury functions in the central government can provide significant communication, visibility and efficiency benefits

- Establish by legislation centralized single treasury functions across Commonwealth agencies and dependent public corporations to enhance visibility, reduce financing costs and improve cash flow June 2016
  - Identify agencies and component units that would be part of the centralized structure January 2016
  - Build the necessary infrastructure for the monitoring and projection of cash flows June 2016
  - Enact legislation to create centralized treasury with provisions that would allow for enforcement June 2016

# Institutional Reform and Transparency

## Institutional Reform and Transparency Measures

## Target Date

### 3.3 Improve Fiscal and Economic Decision-Making

Investors, bondholders, policymakers, and academics have repeatedly pointed to the need of equipping the Commonwealth with more **transparent, reliable and timely macroeconomic data** that complies with global standards. A methodological modernization of the Commonwealth's national accounts is long overdue, along with a **centralized and well-structured approach towards financial and economic development decisions**

- Adopt the Institute of Statistics and the Planning Board 5-year plan to strengthen the economic statistical system and analysis by modernizing national accounts with an estimated investment of \$3 million per year 2015-2020  
(annual targets)

  - Reorganize and expand Puerto Rico's current 5 national accounts into 7 accounts (Net Income and Gross Product, Personal Income and Outlays, Government Receipts and Expenditures, Foreign Transactions-Current, Foreign Transactions-Capital, Gross Savings and Investment and Private Sector Income)
  - Present the national accounting statistics in accordance with the 2008 United Nations standards
  - Develop a new forecasting model for Puerto Rico's national accounts
  - Publish official full-set of quarterly national accounting statistics that is consistent with annual estimates
  - Request technical assistance from the US Bureau of Labor Statistics and the US Bureau of Economic Analysis
- Consolidate the functions of the Treasury Department, OMB and the GDB's non-core banking operations into new Finance and Public Credit Department to better manage and coordinate fiscal and financial policy June 2017

  - Existing fiscal and financial policy is heavily fragmented; international best practices typically consolidate revenue, budget and financial functions to obtain a government-wide visibility and improve execution
- Reorganize the Department of Economic Development and Commerce to better deploy economic promotion resources and shared corporate services

  - Complete DDEC organizational diagnostic with respect to corporate governance, organizational structure, decision-making processes and return on investment philosophy February 2016
  - Submit and pass legislation to implement new DDEC organizational structure and business plan January 2017

# Institutional Reform and Transparency

## **Institutional Reform and Transparency Measures**

## **Target Date**

### **3.3 Improve Fiscal and Economic Decision-Making (cont.)**

- Merge strategic public corporations into a real estate development agency that supplements the Department of Economic Development to improve economic and business planning
  - Centralized entity will serve as a project management coordinator while leveraging resources from current entities and minimizing operational costs via shared services
  - Request to the US Census Bureau that Puerto Rico be included in the Census of Governments and that the National Agricultural Statistical Service provide technical assistance developing agricultural surveys

September 2016

### **3.4 Implement New Budgetary Rules**

Given that the Commonwealth has suffered from chronic **budget deficits** and has repeatedly failed to meet budgetary estimates, it should institute new budgetary rules and practices to impose budgetary discipline and help achieve FEGP targets

- Refer to Summary of Fiscal Responsibility and Economic Revitalization Act of the FEGP

### **3.5 Institute Control Board for Policy Continuity and Compliance**

An independent **fiscal control board, comprised by experienced individuals** from inside and outside the Commonwealth, **shall oversee the implementation of the 5-year FEGP** with the powers necessary to ensure compliance

- Refer to Summary of Fiscal Responsibility and Economic Revitalization Act of the FEGP

# Requests to the US Government

## Federal action is necessary to place Puerto Rico on a sustainable path

Type	Request	Needed for Measure
Long-Term Sustainability	<ul style="list-style-type: none"> <li>▪ Access to a legal framework to restructure the Commonwealth's liabilities in an orderly process</li> </ul>	Financing Gaps
	<ul style="list-style-type: none"> <li>▪ <u>Equitable Medicare and Medicaid treatment and funding</u></li> </ul>	2.7 Control Health Care Costs
	<ul style="list-style-type: none"> <li>- <u>Medicaid</u></li> <li>- Remove statutory limits on Medicaid funding, including not setting the Federal Medical Assistance Percentage ("FMAP") at a fixed percentage               <ul style="list-style-type: none"> <li>❖ Medicaid funding level is capped at ~\$260 million and the FMAP rate set at 50%, which equals an effective rate of 15% to 20%, whereas according to Puerto Rico's income levels should be 83%</li> </ul> </li> </ul>	
	<ul style="list-style-type: none"> <li>- <u>Medicare</u></li> <li>- Reimburse Puerto Rico hospitals who admit patients under the Inpatient Prospective Payment System ("IPPS") at the same rate as mainland hospitals</li> <li>- Make Puerto Rico hospitals eligible for bonus payments under Medicare</li> <li>- Automatically enroll in Medicare Part B individuals enrolled in Medicare Part A</li> <li>- Provide Puerto Rico doctors fair treatment under the Practice Expense Geographic Practice Cost Index ("GPCI") payment formula</li> <li>- Ensure adequate PMPM payments to Medicare Advantage plans in Puerto Rico</li> <li>- Allow adequate utilization of Enhanced Allotment Program ("EAP") prescription drug funding</li> </ul>

## Summary of Measures – Growth, Costs and Total Impact

A summary of the annual impact of the incremental revenue from GNP growth, which is spurred by economic development and structural reforms as determined by the Working Group, is presented below along with a summary of the estimated cost of implementing all of the measures and then the total impact of the growth and measures

- Consistent with the approach taken in the Krueger Report, incremental revenue from economic development and structural reforms is calculated as the difference between a high-growth and a base-case scenario for General Fund revenue sources<sup>(1)</sup>
- The base-case scenario assumes approximately -1% real growth in GNP while the high-growth scenario assumes structural reforms lead to GNP growth of 2% by 2020 (2% inflation is assumed in both cases)
  - In addition, labor reforms are assumed to lead to a greater increase in revenues from personal income taxes, which is calculated using an elasticity factor of 1%, which is also consistent with the Krueger Report
- Incremental costs of the various measures are also shown below and consist of estimates of incremental capex necessary for the measures and growth, incremental pension contributions associated with the measures, cost of earned income tax credits, investment in a new accounting system and the implementation of a new Institute of Statistics plan

<i>\$ millions</i>	2016P	2017P	2018P	2019P	2020P	Total
<b>Total Est. Incremental Rev. from Econ. Dev. and Structural Reforms</b>	–	\$115	\$322	\$584	\$907	\$1,929
<b>Estimated Incremental Cost of Measures</b>	(\$262)	(\$549)	(\$569)	(\$616)	(\$538)	(\$2,533)
<b>Total Impact of Measures</b>						
Revenue Measures	1,121	1,375	1,943	2,506	2,524	9,469
Expense Measures	11	443	1,064	1,538	1,859	4,914
Incremental Cost of Measures	(262)	(549)	(569)	(616)	(538)	(2,533)
<b>Total Impact of Measures</b>	<b>\$870</b>	<b>\$1,269</b>	<b>\$2,439</b>	<b>\$3,428</b>	<b>\$3,845</b>	<b>\$11,850</b>
Est. Incremental Rev. from Economic Development and Structural Reforms	–	115	322	584	907	1,929
<b>Total Impact of Measures and Growth</b>	<b>\$870</b>	<b>\$1,384</b>	<b>\$2,761</b>	<b>\$4,012</b>	<b>\$4,752</b>	<b>\$13,779</b>

(1) General Fund revenue sources include personal income, corporate, SUT/VAT, property, Act 154, alcoholic beverages, cigarettes, motor vehicles, excises on off-shore shipment rum and other taxes. Act 154 taxes are assumed to be held constant in both base- and high-growth scenarios.

---

# Summary of Fiscal Responsibility and Economic Revitalization Act

# Fiscal Responsibility and Economic Revitalization Act

---

**In order to ensure maximum benefit from the FEGP, the Working Group has drafted the Fiscal Responsibility and Economic Revitalization Act (FRERA) that includes measures that will ensure compliance with the FEGP, including the creation of a control board (and other oversight and compliance measures) as well as new budgetary rules**

## **Selected Highlights of FRERA: The Control Board (or the “Board”) Generally**

- Establishes the Board, which will consist of five individuals appointed by the Governor that must have knowledge and expertise in finance, management, or the operation of business or government and must be independent from other governmental entities
- Provides that Board members will serve for 4-year staggered terms
- Requires that a majority of the nominated Board members be selected from a list provided to the Governor by independent third parties
- Gives the Board oversight authority over most governmental entities, including the Commonwealth, GDB and the public corporations (except PREPA and PRASA)
- Assures the Board’s independence by
  - Giving it its own revenue source for operations
  - Allowing it to hire its own independent staff and professionals
  - Removing a board member only for cause
  - Giving it extensive subpoena powers
  - Authorizing it to levy sanctions for non-compliance with approved budgets

# Fiscal Responsibility and Economic Revitalization Act

---

## Selected Highlights of FRERA: Fiscal and Economic Growth Program

- Requires that a Commonwealth-wide consolidated 5-year FEGP be submitted to the Board for approval no later than the end of the 2nd Quarter of FY 2016
- Requires the Board to evaluate whether the proposed FEGP complies with the objectives and requirements provided in the FRERA
- Mandates that the objectives of the FEGP include:
  - Implementing structural reforms that restore economic growth and competitiveness
  - Eliminating, over time, the financing gaps and reducing the debt burden of most governmental entities, including the Commonwealth and public corporations (except PREPA and PRASA)
  - Improving institutional credibility by improving budget formulation and execution and data transparency

# Fiscal Responsibility and Economic Revitalization Act

---

## Selected Highlights of FRERA: FEGP (cont.)

- Requires the FEGP to:
  - Include specific proposals to improve and diversify the economy
  - Incorporate structural and economic reforms to ensure long-term fiscal sustainability and economic development
  - Incorporate best practices for making reliable revenue estimates
  - Require that budgets be prepared and calculated pursuant to the modified accrual basis of accounting according to generally accepted standards
  - Require governmental entities to reduce annually, and by FY 2021, eliminate budget deficits
  - Ensure a material reduction in expenditures through more efficient delivery of services
  - Ensure that pension obligations are sustainable and can be honored over the long term
  - Require that the Commonwealth-wide debt load be adjusted to sustainable terms
  - Require that financial controls and accounting systems be improved to monitor fiscal developments on a timely basis
  - Identify automatic budgetary stabilizers to ensure compliance with the proposed FEGP

# Fiscal Responsibility and Economic Revitalization Act

---

## Selected Highlights of FRERA: Approval of, and Monitoring Compliance with, the FEGP

- Requires the Board to review and approve the consolidated Fiscal and Economic Growth Plan if it complies with the objectives and requirements set forth in FRERA
- Requires certain entities to submit annual budgets to the Board to ensure that they comply with the approved Fiscal and Economic Growth Plan
- Requires the Board to evaluate whether the budgets comply with the Fiscal and Economic Growth Plan
- Requires the Board to issue non-compliance findings if the budgets do not comply with the Fiscal and Economic Growth Plan
- Requires the Board to monitor compliance with the approved budgets throughout each fiscal year
- Requires the Board to issue non-compliance warnings during the fiscal year or findings at the end of the fiscal year if the entities' actual revenues and expenditures vary from the approved budget in an amount that exceeds a permitted variance determined by the Board
- Imposes severe sanctions for failing to comply with approved budgets, which may include:
  - A prohibition on entering into contracts
  - Automatic hiring freezes
  - Automatic expense cuts (see next slide)

# Fiscal Responsibility and Economic Revitalization Act

---

## Selected Highlights of FRERA: New Budgetary Rules for the Commonwealth General Fund

- Provides that the Commonwealth budget be based on a “Revenue Projection” validated by third parties
- Requires that the budget include a 5-year revenue and expense projection
- Prohibits the creation or use of budgetary funds without an identified source of revenues and cancels several existing budgetary funds that do not have identified sources of revenues
- All purchase orders and contracts with third-party suppliers will be subject to OMB budgetary oversight and uniform procedures for approval and recording
- Creates a special fund that may only be used to pay the government’s accounts payable, including tax refunds; amounts to be deposited in such fund shall not be included in the Revenue Projection
- Provides that the Secretary of the Treasury shall adjust each fiscal year’s actual revenue numbers by the difference between the projection of tax refunds made at the beginning of the fiscal year and the revised projections of tax refunds made near the end of the fiscal year
- Provides that a specified amount of each fiscal year’s budget be allocated to a “Budgetary Reserve Fund” until amounts credited to such fund reach a specified percentage of the then-current fiscal year’s Revenue Projection
- Provides that budgetary expenditures for each fiscal year cannot exceed such fiscal year’s Revenue Projection less the amount allocated to the “Budgetary Reserve Fund” amount
- Provides that the Budgetary Reserve Fund may only be used for certain specified purposes
- Mandates that the budget identify a specified amount of operating expenditures that may not be incurred unless OMB (and in some cases the Board) authorizes the use of such funds (known as the “Sequestered Expenditures”)
- Provides that a portion of the Sequestered Expenditures shall be released by the OMB or the Board at the end of each fiscal quarter if actual revenues meet or exceed the Revenue Projection
- Provides that if actual revenues are below the Revenue Projection, the Sequestered Expenditures shall not be released
- Provides that the OMB or the Board may also decide not to release the Sequestered Expenditures to specific entities if it determines that such entities’ actual expenditures will exceed its budgeted expenditures

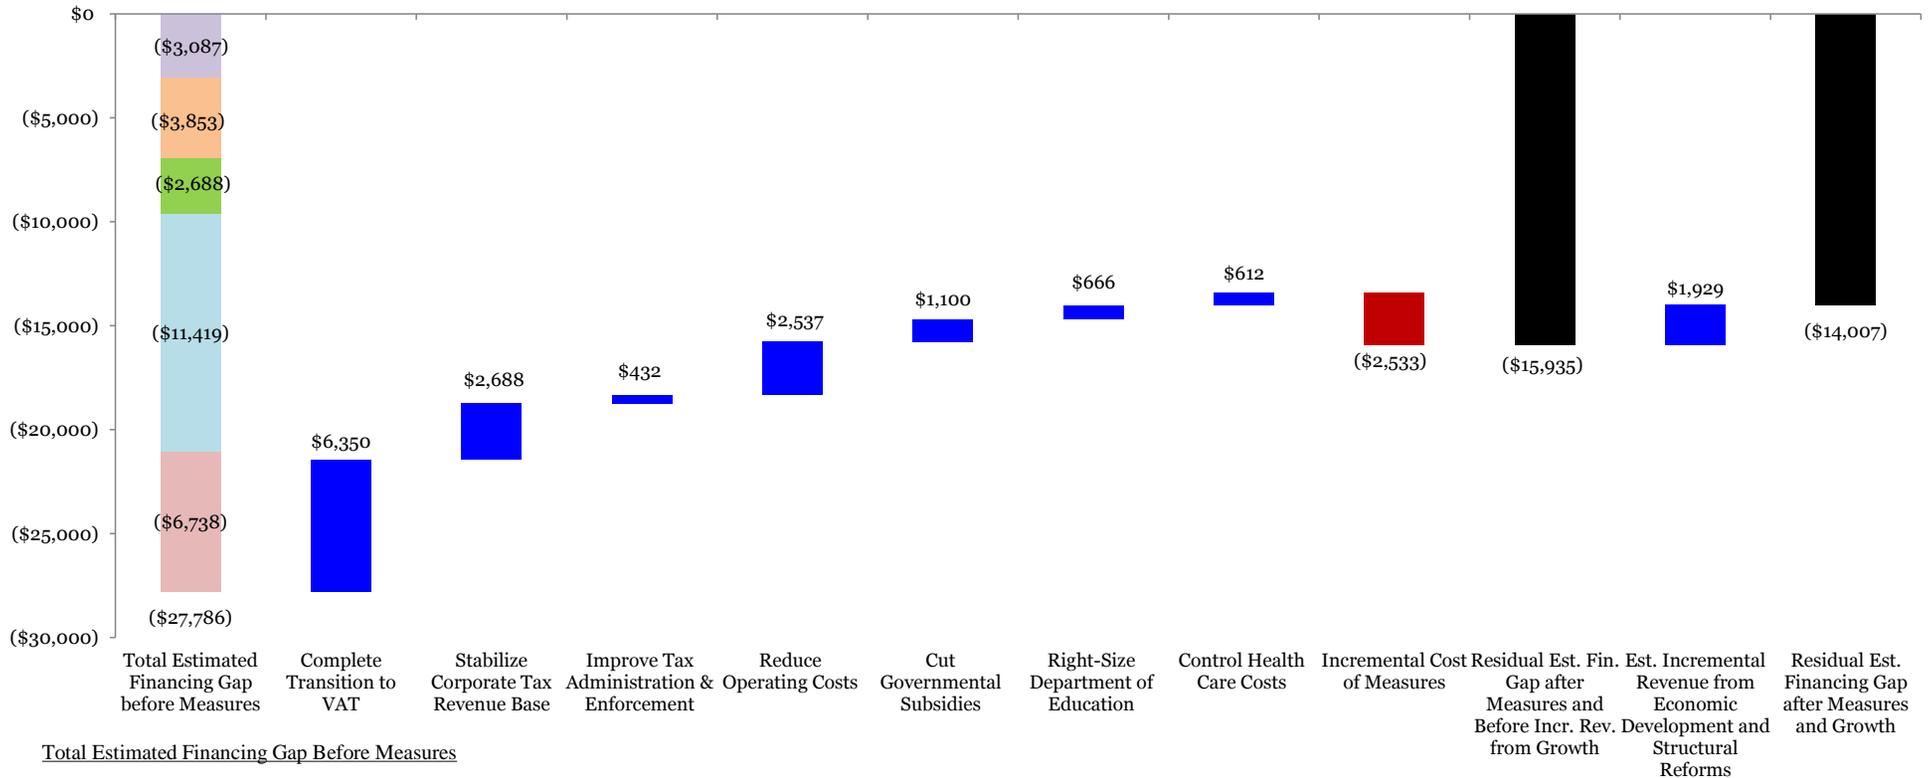

---

# Summary of Projected Financing Gap After Measures

# Cumulative Financing Gap Before and After Measures

A summary of the cumulative financing gap before measures from FYs 2016 to 2020<sup>(1)</sup> and the total benefit from each measure over the same period, as determined by the Working Group, is shown below

Cumulative 5-Year Financing Gap (\$ millions)

Total Estimated Financing Gap Before Measures

- Base Financing Deficit before Loss of ACA, Loss of Act 154 and Debt Service and after AUCs and Catch-up Payments to Retirement Systems
- Loss of ACA Funding
- Loss of Act 154 / Foreign Company Tax Losses
- Debt Service - Interest
- Debt Service - Principal

(1) Note that the financing gap before measures has been updated from the Krueger Report, based on new information obtained through diligence by the Working Group. The variances to the Krueger Report are detailed in the appendix.

# Annual Financing Surplus (Gap) Before Debt Service

Based on the Working Group's diligence and the measures previously outlined, the following presents a summary of the estimated annual financing gaps prior to the payment of debt service, but after the implementation of the measures previously outlined

## Projected Financing Surplus/(Gap) before Debt Service (\$ millions)

	2016P	2017P	2018P	2019P	2020P	Total
Total Estimated Financing Gap before Measures (incl. Debt Service)	(\$4,075)	(\$4,386)	(\$4,670)	(\$7,437)	(\$7,217)	(\$27,786)
Consolidated Interest	2,320	2,370	2,320	2,239	2,170	11,419
Consolidated Principal	1,810	1,044	957	1,628	1,299	6,738
Pre-Measures & Pre-debt Service Financing Surplus/(Gap)	55	(972)	(1,392)	(3,571)	(3,749)	(9,628)
<u>Revenue Measures</u>						
Complete Transition to VAT	1,111	1,290	1,303	1,316	1,330	6,350
Stabilize Corporate Tax Revenue Base	–	–	538	1,075	1,075	2,688
Improve Tax Administration & Enforcement	10	85	103	115	119	432
Total Revenue Measures	1,121	1,375	1,943	2,506	2,524	9,469
<u>Expense Measures</u>						
Reduce Operating Costs	3	165	550	840	979	2,537
Cut Governmental Subsidies	–	50	200	350	500	1,100
Right-Size Department of Education	12	78	135	193	249	666
Control Health Care Costs	(4)	151	179	155	131	612
Total Expense Measures	11	443	1,064	1,538	1,859	4,914
Incremental Cost of Measures <sup>(1)</sup>	(262)	(549)	(569)	(616)	(538)	(2,533)
<b>Fin. Surplus before Debt Serv. ex. Economic Growth</b>	<b>\$924</b>	<b>\$298</b>	<b>\$1,046</b>	<b>(\$143)</b>	<b>\$97</b>	<b>\$2,222</b>
Est. Incremental Revenue from Economic Development and Structural Reforms	–	115	322	584	907	1,929
<b>Financing Surplus before Debt Service</b>	<b>\$924</b>	<b>\$413</b>	<b>\$1,369</b>	<b>\$442</b>	<b>\$1,003</b>	<b>\$4,150</b>

(1) Includes estimates of incremental capex necessary for the measures and growth, incremental pension contributions associated with the measures, cost of earned income tax credits, investment in a new accounting system and the implementation of a new Institute of Statistics plan.

# Unsustainability of Existing Debt Service Absent Economic Growth

Even after taking the measures outlined on the previous pages, the FEGP suggests that the Commonwealth cannot service all of its debt as currently scheduled

- Since economic growth is dependent in many ways on elements outside of the Commonwealth's control (such as changes to certain federal government policies), the following exhibit presents the forecasted financing gaps after debt service excluding the estimated impact of GNP growth from economic development and structural reforms
- The financing gap below is shown for illustrative purposes only based on consolidated debt service and with GO bond and GO guaranteed bond debt service<sup>(1)</sup> separately delineated

## Total Projected Financing Surplus/(Gap) Excluding Economic Growth (\$ millions)

	2016P	2017P	2018P	2019P	2020P	Total
<b><u>Financing Gaps Based on Consolidated Interest and Principal</u></b>						
Fin. Surplus before Debt Serv. and Est. Incr. Rev. from Econ Dev. And Struct. Reforms	\$924	\$298	\$1,046	(\$143)	\$97	\$2,222
Consolidated Interest <sup>(2)</sup>	(2,320)	(2,370)	(2,320)	(2,239)	(2,170)	(11,419)
Financing Gap after Consolidated Interest	(1,396)	(2,073)	(1,274)	(2,382)	(2,073)	(9,197)
Consolidated Principal <sup>(2)</sup>	(1,810)	(1,044)	(957)	(1,628)	(1,299)	(6,738)
<b>Total Financing Gap before Economic Growth</b>	<b>(\$3,205)</b>	<b>(\$3,117)</b>	<b>(\$2,231)</b>	<b>(\$4,010)</b>	<b>(\$3,372)</b>	<b>(\$15,935)</b>
<b><u>Financing Gaps with GO and GO Guaranteed Debt Service Delineated</u></b>						
Fin. Surplus before Debt Serv. and Est. Incr. Rev. from Econ Dev. And Struct. Reforms	\$924	\$298	\$1,046	(\$143)	\$97	\$2,222
GO and GO Guaranteed Interest <sup>(1)</sup>	(920)	(953)	(932)	(895)	(860)	(4,561)
GO and GO Guaranteed Principal <sup>(1)</sup>	(925)	(526)	(433)	(483)	(553)	(2,920)
Financing Surplus after GO and GO Guaranteed Debt Service	(921)	(1,182)	(319)	(1,521)	(1,317)	(5,259)
Interest Excluding GO and GO Guaranteed	(1,400)	(1,418)	(1,387)	(1,345)	(1,309)	(6,859)
Financing Gap after GO and GO Guaranteed and All Interest	(2,320)	(2,599)	(1,707)	(2,865)	(2,626)	(12,118)
Principal excluding GO and GO Guaranteed	(885)	(518)	(524)	(1,144)	(746)	(3,818)
<b>Total Financing Gap before Economic Growth</b>	<b>(\$3,205)</b>	<b>(\$3,117)</b>	<b>(\$2,231)</b>	<b>(\$4,010)</b>	<b>(\$3,372)</b>	<b>(\$15,935)</b>

(1) GO and GO guaranteed debt service includes debt service payments related to GO, GDB GO guaranteed bonds, PBA and PRIFA Bond Anticipation Notes ("BANs"). Excludes PRASA and GDB guaranteed intragovernmental loans.

(2) Includes any debt service payments related to debt at GO, GDB, PBA, Public Finance Corporation ("PFC"), COFINA, PRIFA, UPR, Puerto Rico Convention Center District Authority ("PRCCDA"), Puerto Rico Industrial Development Company ("PRIDCO"), GSA, PRIFA BANs, ERS and HTA.

## Unsustainability of Existing Debt Service Even with Economic Growth

Even if the Commonwealth were able to achieve economic growth, the estimated benefit of such growth still would not be enough to allow the Commonwealth to pay all of its contractual debt service as currently scheduled

- The financing gap presented below is shown after the estimated benefit of economic growth; as with the previous page, the financing gap is shown based on consolidated debt service and with GO bond and GO guaranteed bond debt service<sup>(1)</sup> separately delineated

### Total Projected Financing Surplus/(Gap) Including Economic Growth (\$ millions)

	2016P	2017P	2018P	2019P	2020P	Total
<b>Financing Gaps Based on Consolidated Interest and Principal</b>						
Financing Surplus before Debt Service	\$924	\$413	\$1,369	\$442	\$1,003	\$4,150
Consolidated Interest <sup>(2)</sup>	(2,320)	(2,370)	(2,320)	(2,239)	(2,170)	(11,419)
Financing Gap after Consolidated Interest	(1,396)	(1,958)	(951)	(1,798)	(1,166)	(7,269)
Consolidated Principal <sup>(2)</sup>	(1,810)	(1,044)	(957)	(1,628)	(1,299)	(6,738)
<b>Total Financing Gap</b>	<b>(\$3,205)</b>	<b>(\$3,002)</b>	<b>(\$1,909)</b>	<b>(\$3,425)</b>	<b>(\$2,465)</b>	<b>(\$14,007)</b>
<b>Financing Gaps with GO and GO Guaranteed Debt Service Delineated</b>						
Financing Surplus before Debt Service	\$924	\$413	\$1,369	\$442	\$1,003	\$4,150
GO and GO Guaranteed Interest <sup>(1)</sup>	(920)	(953)	(932)	(895)	(860)	(4,561)
GO and GO Guaranteed Principal <sup>(1)</sup>	(925)	(526)	(433)	(483)	(553)	(2,920)
Financing Surplus after GO and GO Guaranteed Debt Service	(921)	(1,067)	3	(936)	(410)	(3,331)
Interest Excluding GO and GO Guaranteed	(1,400)	(1,418)	(1,387)	(1,345)	(1,309)	(6,859)
Financing Gap after GO and GO Guaranteed and All Interest	(2,320)	(2,484)	(1,385)	(2,281)	(1,719)	(10,189)
Principal excluding GO and GO Guaranteed	(885)	(518)	(524)	(1,144)	(746)	(3,818)
<b>Total Financing Gap</b>	<b>(\$3,205)</b>	<b>(\$3,002)</b>	<b>(\$1,909)</b>	<b>(\$3,425)</b>	<b>(\$2,465)</b>	<b>(\$14,007)</b>
<i>Memo: Total Financing Gap ex. Est. Incremental Revenue from Economic Development and Structural Reforms</i>	<i>(\$3,205)</i>	<i>(\$3,117)</i>	<i>(\$2,231)</i>	<i>(\$4,010)</i>	<i>(\$3,372)</i>	<i>(\$15,935)</i>

(1) GO and GO guaranteed debt service includes debt service payments related to GO, GDB GO guaranteed bonds, PBA and PRIFA BANS. Excludes PRASA and GDB guaranteed intragovernmental loans.

(2) Includes any debt service payments related to debt at GO, GDB, PBA, PFC, COFINA, PRIFA, UPR, PRCCDA, PRIDCO, GSA, PRIFA BANS, ERS and HTA.

---

# Conclusion

# Conclusion

---

- Even after the implementation of the FEGP, which is subject to significant political and execution risks, the Working Group's projections suggest that the Commonwealth cannot meet all of its debt service requirements as currently scheduled and must restructure its liabilities. Further, without significant changes in federal policies, particularly in health care and economic development, the ability of the Commonwealth to meet its debt service costs while providing essential services to its residents will be severely challenged
- While the Working Group recognizes that a restructuring of the Commonwealth's debt would result in hardship to individual bondholders, the Working Group believes that, unless the persistent stagnation of Puerto Rico's economy that has helped fuel the increase in Government debt over the past decade can be reversed, the public debt is not sustainable
- Therefore, in order to make the greatest amount of the debt sustainable in the long term, priority has to be given to:
  - Reigniting Puerto Rico's economic growth in the short- and medium-term;
  - Providing essential services, including health, education and safety, to the people of Puerto Rico, the continued deterioration of which will exacerbate the Commonwealth's negative demographic trends, adversely affect its economic prospects and erode its tax base; and
  - Ensuring government can sustain its pension obligations
- The Fiscal and Economic Growth Plan was designed with these priorities in mind

## Conclusion (cont.)

---

- As difficult as debt restructuring is likely to be, the Working Group has instructed its advisors to begin working on a voluntary exchange offer to be made to its creditors as part of the implementation of the Fiscal and Economic Growth Plan
- In the design of the voluntary exchange offer, the Working Group has directed its advisors to take into account the priority accorded to various debt instruments across the Puerto Rico debt complex, including its GO debt, while recognizing that, even assuming the clawback of revenues supporting certain Commonwealth tax-supported debt, available resources may be insufficient to service all principal and interest on debt that has a constitutional priority
- Therefore, a consensual compromise of the creditors' competing claims to the Commonwealth's revenues to support debt service will be required in order to avoid a destabilizing default on the Commonwealth's debt and to avoid a legal morass that will further destabilize the Commonwealth's economy and finances
- Accordingly, the Working Group has directed its advisors to meet with the creditor groups that have already been organized (and those that may be formed hereafter) to explain the Fiscal and Economic Growth Plan and to begin negotiation of the terms of a voluntary exchange offer that can garner widespread creditor acceptance
- **It is the Working Group's belief that a voluntary adjustment of the terms of the Commonwealth's debt that allows the measures contained in the FEGP to be implemented is the best way to maximize all creditor recoveries**

---

# Appendix

# Bridge from Budget to Conway

## Risk Adjustments to FY 2016 Budget

- The FY 2016 general fund budget, which is included in the CM TSA adjusted cash flow was adjusted for the potential risks below:
  - Revenue risk shortfall of \$306.4 million is primarily attributable to unfavorable revenue variances for May 2015 and June 2015
  - Litigation settlement of \$5.1 million (not included in the FY 2016 budget related to the Dept. of Health)
  - Debt risk of \$402.0 million is primarily related to debt obligations owed to GDB, for bonds held in the GDB portfolio, and debt service payments related to the Puerto Rico Public Finance Corporation, as follows:
    - ☞ \$308.3 million – contractually obligated debt payments for FY 2016 related to obligations owed to GDB. These debt service payments were not approved by the Legislative Assembly in the FY 2016 budget. Payment of this debt on terms other than the contractual terms could have a negative impact on GDB’s liquidity and its ability to pay obligations as they become due
    - ☞ \$93.7 million – the Legislative Assembly may appropriate for PFC debt service in FY 2016
  - A proposed Economic Development and Obligations Payment Fund totaling \$275.0 million has been created to be used for economic development initiatives and/or the payment of obligations pending legislative approval

### Risk Adjustment to General Fund Budget (\$ millions)

	<u>FY 2016</u>
Revenue	(\$306)
Litigation settlement	(5)
Debt	(402)
Economic Development & Obligations Payment Fund	275
<b>Budget Adjustments</b>	<b>(\$439)</b>

# Bridge from Conway to the Krueger Report

## Reconciliation of Conway and Krueger Reports

- The Krueger Report measured a deficit under an approach that is different than Conway's approach in the following areas: the Krueger Report generally used an accrual accounting method as compared to cash; the Krueger Report's methodology included GDB debt owed to third-parties versus Conway's approach that included debt obligations owed to GDB; and finally, the Krueger Report's scope included the broader Commonwealth financial position and Conway's approach only includes inflows and outflows of the TSA account as noted below:

- FY 2016 General Fund budget
- Federal funds
- Net pension benefits
- Non-General Fund revenue/expenses through the TSA
- CM Risk Adjustments to the TSA (debt, working capital, etc.)
- Commonwealth's Liquidity Enhancement Measures
- Select Component Units (ASES, PRITA, UPR, PBA, ASEM)
- CM's analysis does not include cash flow projections for the following:
  - ☞ Component Units, aside from the five noted above
  - ☞ Non-General Fund governmental funds
  - ☞ Special revenue funds
  - ☞ Special debt funds
  - ☞ Capital project funds
  - ☞ Non-major proprietary funds
  - ☞ Other non-governmental and fiduciary funds
  - ☞ Municipalities and the Municipal Property Tax Collection Center ("CRIM")
- Conway's analysis does not include cash flow projections for the following:
  - ☞ Litigation risk
  - ☞ Budget adjustment risk – reduction in spending from FY 2015 to FY 2016
  - ☞ Spending in excess of appropriations
  - ☞ Federal funding risk
  - ☞ Unfavorable economic factors
  - ☞ Extraordinary expenses associated with any restructuring activities

## Conway to Krueger Report Bridge (\$ millions)

	CM Adj. TSA CF	Liq. Outlook	FY 2016
Krueger Deficit (after revenue measures)	(\$2,518)	–	(\$2,518)
Tax and Non-Tax Variance	(73)	150	77
GDB Net Operating Revenue	(130)	–	(130)
Other Fund Inflows	36	–	36
<b>Total Inflows<sup>(1)</sup></b>	<b>(167)</b>	<b>150</b>	<b>(17)</b>
General Fund Budget	143	(183)	(41)
Net Op. Deficit of Non-GF Gov. Funds	362	–	362
Net Op. Deficit of Non-Enterprise Comp. Units	350	(193)	157
Capital Expenditures	300	–	300
Due to Intragovernmental	–	(500)	(500)
FY 2015 Deferred Appropriations (Ex. Debt)	(124)	–	(124)
<b>Non-debt Related Outflows<sup>(1)</sup></b>	<b>1,031</b>	<b>(876)</b>	<b>155</b>

<b>Total Variance</b>	<b>\$1,992</b>	<b>(\$1,277)</b>	<b>\$716</b>
<b>CM Liquidity Outlook<sup>(3)</sup></b>	<b>(\$525)</b>	<b>(\$1,277)</b>	<b>(\$1,802)</b>

Source: Krueger Report

Note: Terms defined herein are referenced in more detail within Conway MacKenzie's Liquidity Update of the Commonwealth of Puerto Rico (Aug. 25, 2015).

(1) Variance of inflows and outflows are net of Federal Funds which have a net zero impact. Krueger reports \$6.5 billion where CM's TSA cash flow includes \$3.0 billion.

(2) GDB debt variances totaling \$570 million are related to a different approach in debt disbursements. CM's report includes debt due to GDB, the Krueger Report includes debt owed to third-parties.

(3) The bank to book reconciliation as of June 30, 2015 was approximately \$442.6 million. This risk is not included in the reconciliation above, but is noted in Conway's report.

# Adjustments to the Krueger Report

---

**As part of its development of the FEGP, the Working Group reviewed not only the reform measures identified in the Krueger Report, but also the estimates in the Krueger Report for the Commonwealth's financing gaps before the impact of the measures**

- The Working Group's estimate of the total financing gaps facing the Commonwealth generally followed the approach outlined in the Krueger Report
- However, a review of the basis for many of the estimates in the Krueger Report resulted in numerous changes, including:
  - Revised revenue forecasts that incorporated actual results for 2015 that were not available to the Krueger team at the time its report was issued
  - More detailed component unit projections developed by Conway MacKenzie after the release of the Krueger Report
  - Revised capital expenditure estimates on a by-project rather than simply based on historical numbers as was done in the Krueger Report
  - Revised budgetary expense projections from OMB as well as the adjustment of an overestimation of certain expenses (and the resulting impact of Law 66 on these expenses) included in the Krueger Report
- ∞ The revised OMB projections included revised estimates of required additional uniform pension contributions that in turn impacted the estimated shortfalls in the retirement funds that were included in the Krueger Report

# Adjustments to the Krueger Report (cont.)

---

- In addition, the decision was made to incorporate HTA into the projections, unlike in the Krueger Report
  - Excluding federal grants, the majority of HTA's revenues come from gas and petroleum taxes collected by the Commonwealth
  - In addition, HTA has been funded with over \$2 billion of loans from GDB
  - Based on these factors, it was determined that HTA should be included in the model to capture a holistic view of Commonwealth-supported entities and resulting deficits on a consolidated basis, as was the goal of the methodology outlined in the Krueger Report
- These changes, the Adjusted Estimates, were reviewed with, and reflect the input of, members of the Krueger team
- The following pages provide a summary bridge from the Krueger Report to the Adjusted Estimates (the consolidated adjusted estimates are also presented earlier in the presentation)

# Bridge from Krueger to Adjusted Estimates

The following exhibit presents a summary of the variances between the Krueger Report and the Adjusted Estimates (prior to the implementation of any measures)

## Bridge from Krueger Report to Adjusted Estimates (\$ millions)

	2016P	2017P	2018P	2019P	2020P	Comments
<b>Krueger Report Fin. Gap Bef. Measures</b>	<b>(\$3,676)</b>	<b>(\$4,169)</b>	<b>(\$5,893)</b>	<b>(\$7,028)</b>	<b>(\$7,147)</b>	
<u>Variations in Adjusted Estimates</u>						
General Fund and Other Select Revenues	(83)	(152)	(194)	(236)	(279)	Revised revenue estimates that incorporate preliminary actual 2015 results that were lower than what had been estimated in the Krueger Report; 2015 revenues form the base for future year estimates. Comparison shown is against the sum of Krueger Report tax and non-tax revenues
GDB Net Operating Revenue (including PRIFA crudita receipts and PRIFA Petroleum Receipts)	(385)	(287)	(82)	(45)	(84)	Revised forecast from GDB. Note that the differential is shown after a deduction of PRIFA BAN debt service (which, in the Adjusted Estimates, is shown in the debt service line, whereas in the Krueger Report it was embedded in the GDB Operating Revenue line). Adjusted Estimates do not include any new loans to the municipalities, only funding on existing lines
COFINA SUT Collection	15	15	16	16	16	Revised forecast based on revised revenue estimates and the development of a waterfall model that projects the SUT allocations; the Krueger Report set COFINA revenues equal to COFINA debt service

# Bridge from Krueger to Adjusted Estimates (cont.)

## Bridge from Krueger Report to Adjusted Estimates (\$ millions)

	<b>2016P</b>	<b>2017P</b>	<b>2018P</b>	<b>2019P</b>	<b>2020P</b>	<b>Comments</b>
HTA Operating Income and Debt Service (ex. Capex)	75	124	172	191	191	HTA is included in the Adjusted Estimates but was excluded from the Krueger Report; numbers here are shown inclusive of all revenues, expenditures (ex. capital expenditures shown in the capital expenditures variance line) and debt service
GF budget (ex. Debt Service and Additional Uniform Contributions)	(102)	(280)	(75)	74	169	Revised budget per OMB as well as adjustment of an overestimation contained in the Krueger Report of certain expenses (and the resulting impact of Law 66 on these expenses). Adjusted Estimates exclude additional uniform contributions for illustrative purposes, whereas the Krueger Report had included the additional uniform contributions in this line (though at a lower amount than included in the most recent OMB projections). In the Adjusted Estimates, ERS debt service was also deducted from the ERS appropriations embedded in the General Fund budget from OMB and then included in the principal and interest lines; the Krueger Report embedded ERS debt service in the retirement shortfall

# Bridge from Krueger to Adjusted Estimates (cont.)

## Bridge from Krueger Report to Adjusted Estimates (\$ millions)

	2016P	2017P	2018P	2019P	2020P	Comments
Additional Uniform Contributions as Compared to Retirement Shortfall	(194)	88	458	(78)	70	Adjusted Estimates run through higher additional uniform contributions, which reduce the "Retirement Shortfall"; the comparison shown here represents the Additional Uniform Contribution in the Adjusted Estimates (including certain catch-up payments) as compared to the Retirement Shortfall shown for each year in the Krueger Report as well as the AUC embedded in the Krueger Report "GF Budget" line. Adjusted Estimates exclude \$58 million annually of estimated AUCs required by municipalities that have historically relied on limited GDB liquidity to fund
Non-General Fund Government Funds	127	129	130	131	132	Represents revised estimates of "non-budgeted funds." Excludes any losses from agencies with independent treasuries, which were included in the Krueger Report, based on further diligence and the inclusion of such outflows in other lines (namely, capex)
Component Units ex. Capex	230	413	256	552	687	Updated for detailed component unit projections that were not available at the time of the Krueger Report
Capital Expenditures	(86)	(285)	(245)	(203)	(38)	Krueger Report based on most recent historical estimates. Adjusted Estimates based on actual schedule of projects not available at the time of the Krueger Report. Adjusted Estimates do not include municipal capital expenditures, which have historically been largely funded by the Commonwealth and GDB

# Bridge from Krueger to Adjusted Estimates (cont.)

## Bridge from Krueger Report to Adjusted Estimates (\$ millions)

	2016P	2017P	2018P	2019P	2020P	Comments
Change in Payables	450	(377)	(51)	(51)	(51)	Krueger Report had made a blanket assumption of a constant reduction in payables; Adjusted Estimates include a more detailed analysis that reduces payables to ~35 days payable outstanding, assumes different repayment periods for different types of payables (i.e., tax refunds are paid on an accelerated schedule as compared to certain other payables), and that the repayment of payables does not begin until FY 2017
Change in Deposits and Deposit Replenishment	(551)	(500)	–	–	–	Based on updated deposit balance information that was not available at the time of the Krueger Report; Amount required for GDB to meet its estimated minimum statutory liquidity requirement of \$350 million and the Commonwealth to have \$1.0 billion of total deposits on hand by FY 2016 and \$1.5 billion by FY 2017
Inflows from Other Entities	105	–	–	–	–	Represents identified inflows from entities outside the model used to cover expenses in the FY 2016 budget
Loss of ACA Funding	–	–	474	(597)	(730)	Updated per revised estimates based on further diligence done on ASES that was not available at the time of the Krueger Report
Act 154 / Foreign Company Tax Losses	–	894	365	(163)	(154)	Updated based on revised diligence conducted with PRIDCO. The impact of the loss of Act 154 is not assumed to begin until halfway through FY 2018
Total Variances in Adjusted Estimates	(\$399)	(\$217)	\$1,224	(\$409)	(\$70)	
<b>Adjusted Estimates before Measures</b>	<b>(\$4,075)</b>	<b>(\$4,386)</b>	<b>(\$4,670)</b>	<b>(\$7,437)</b>	<b>(\$7,217)</b>	

# Total Public Sector Debt

The following summarizes total public sector debt as of June 30, 2015

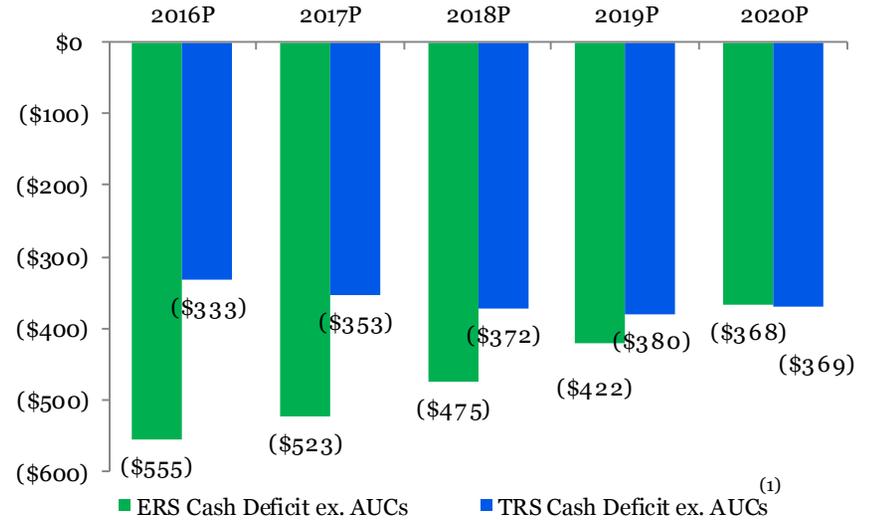

<u>Total Public Sector Debt Outstanding (\$ millions)</u>	
	<u>6/30/15</u>
Full Faith and Credit Bonds and Notes Issued by the Commonwealth	\$13,061
Bonds and Notes Guaranteed by the Commonwealth	<u>5,547</u>
<b>Subtotal</b>	<b>18,608</b>
Debt Supported by Commonwealth Appropriations or Taxes	4,047
Tax and Revenue Anticipation Notes	<u>300</u>
<b>Subtotal - Debt Payable from the General Fund</b>	<b>22,955</b>
Bonds and Notes Payable from Sales and Use Tax Revenue (COFINA)	15,224
Debt Issued by Public Corporations and Other Instrumentalities	23,877
Debt Issued by Municipalities	4,126
Pension Funding Bonds (Payable from Employer Contributions to ERS)	2,948
Other Limited Obligations Debt and Non-recourse Debt	<u>1,987</u>
<b>Subtotal - Other Public Sector Debt</b>	<b>48,162</b>
<b>Total Public Sector Debt</b>	<b><u>\$71,117</u></b>

Note: Not all entities included in the chart above are included in the Adjusted Estimates, consistent with the Krueger Report.

# Retirement Systems Assumptions, Asset Balances and Cash Flows

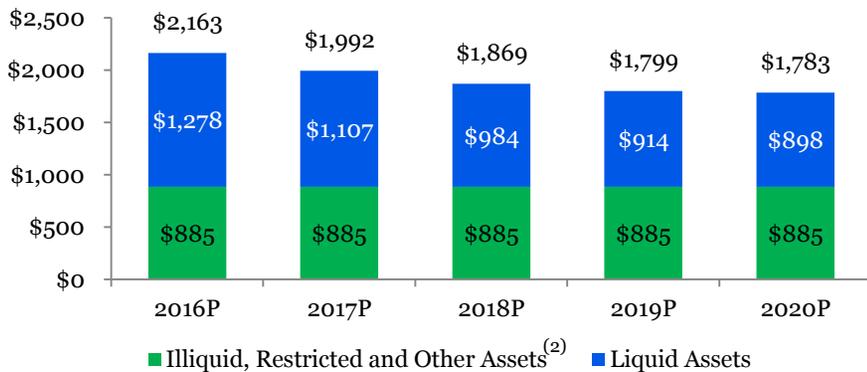

- The following charts summarize the declining asset portfolios of the retirement plans and certain assumptions embedded therein for purposes of developing the FEGP
- Key baseline assumptions include:
  - ERS:** ~2% payroll growth starting in FY 2018, begin to receive AUCs of \$352 mm in FY16, assuming the receipt of past-due contributions from the General Fund, municipalities and public corporations
  - TRS:** ~2% payroll growth starting in FY 2018, begin to receive AUCs of \$30 mm in FY17 & 18 and \$510mm from FY19 forward
  - JRS:** Modeled per June 30, 2014 actuarial valuation cash flows; projected ending balance in FY 2016 of ~\$30 mm expected to be depleted by FY 2018, after which it is assumed that General Fund employs “pay-go” funding of ~\$20 mm per year
- In a scenario that includes accelerated attrition, each retirement plan’s stock of assets would decline faster, necessitating larger AUCs from the central government
- Failure of municipalities or agencies to make contributions would exacerbate asset declines; historically, agencies and municipalities have relied on, among other sources, short-term financing from GDB and others to make such payments and that funding source may not be available going forward

**ERS and TRS Yearly Cash Deficits Ex. AUC (\$ millions)**

	2016P	2017P	2018P	2019P	2020P
ERS AUCs	\$428	\$352	\$352	\$352	\$352
TRS AUCs	–	\$30	\$30	\$510	\$510

**ERS Ending Asset Balance (\$ millions)**

**TRS Ending Asset Balance (\$ millions)<sup>(1)</sup>**

Note : All data sourced by preliminary data from the actuarial firm’s valuation reports and incorporating certain assumptions from ERS, TRS and GDB. All figures are preliminary in nature and subject to substantial revision pending a complete review of the retirement plans by the actuarial firm based on the latest available actual figures. Many factors affecting the pension are outside their control including actual performance of asset portfolios, plan participant attrition rates, general fund budgeting and policy decisions. These projections may not adhere to GASB accounting. None of the actuarial firm, ERS, TRS or GDB conducted a comprehensive evaluation of these projections and none of the aforementioned parties makes any representation or warranty, express or implied, as to the accuracy or completeness of the assumptions herein.

(1) Projections based valuation as of June 30, 2014, and not updated for FY 2015 performance. Important to note that actual payroll benefit payments were ~\$100 mm higher in FY 2015 and projected to be ~\$120 mm higher in FY 2016 than the baseline projection from the latest actuarial valuation. Potentially, this trend could continue, which could, in turn, lead to a higher AUC estimate for TRS once the June 30, 2015 valuation is performed.  
 (2) Illiquid, Restricted and Other Assets includes restricted cash, unrestricted cash at GDB and COFINA investments, net of accrued liabilities.

# Footnotes for Financing Gaps Before Measures (p. 17)

1. General Fund and Other Select Revenues include General Fund revenues as well as transfers from the Municipal Revenues Collection Center (known as "CRIM") and hotel tax revenues received by PRCCDA, consistent with the Krueger Report. Revenue estimates were revised to reflect greater knowledge of actual collections in 2015 as well as additional diligence done on certain tax revenues, in particular, those associated with the sales and use tax ("SUT") and the foreign entity tax (Act 154).
2. GDB net operating revenue includes net cash flows from its loan portfolio to entities outside of the scope of the Adjusted Estimates as well as PRIFA petroleum tax receipts (which provide an average of \$310 million per year over the projection period). The Krueger Report had netted payments on account of the PRIFA BANs, but in the Adjusted Estimates the debt service associated with the PRIFA BANs is included in the interest and principal lines. Estimates were also revised by GDB. Projections do not include any new loans to the municipalities, only funding on existing lines.
3. COFINA revenues were estimated using a SUT tax waterfall based on current policies and information developed by the Commonwealth. The revenues shown each year correspond to the Pledged Sales Tax Base Amount as defined in the COFINA bond documents. The Krueger Report had set COFINA revenues equal to COFINA debt service.
4. Unadjusted since the Krueger Report.
5. HTA revenues include gas taxes, license fees, toll receipts, investments, petroleum taxes, cigarette taxes, Tren Urbano related receipts for FY2016, and other highway and operating receipts. The HTA projections assume the Tren Urbano is transferred to PRITA in FY 2017.
6. Based on revised estimates of the budget from OMB. Excludes identified additional uniform contributions and debt service. Also adjusts appropriations to PBA and UPR to deduct debt service (which is then included in the principal and interest lines shown separately, similar to the Krueger Report).
7. Additional uniform contributions related to General Fund payments to fund the retirement systems and certain catch-up payments related to unpaid AUC amounts in FY 2014 and FY 2015. Also includes component units which have not budgeted for additional uniform contributions. Excludes \$58 million annually of estimated AUCs required by municipalities which, if not funded, would further deplete assets in the retirement system.
8. Represents revised estimates of "non-budgeted funds." Excludes any losses from agencies with independent treasuries, which were included in the Krueger Report, based on further diligence and the inclusion of such outflows in other lines (namely, capex).
9. Component unit estimates exclude estimated capital expenditures (which are included in the capital expenditure line) and other delineated expenses and risks, such as the loss of ACA funding. Once these items are accounted for, the total impact of the component units on the overall financing gap is negative.
10. Capital expenditures based on GDB forecast of recommended projects not available at the time of the Krueger Report and includes maintenance capex and capex related to regulatory compliance, construction in progress, judgements, emergencies, and extraordinary maintenance and repairs. Does not include municipal capital expenditures, which have historically been largely funded by the Commonwealth via bond issuances and GDB credit facilities.
11. Unadjusted since the Krueger Report.
12. HTA expenditure includes highway and Tren Urbano disbursements, excluding capital expenditures and debt service and including the payment of past-due payables. Tren Urbano related disbursements after FY16 represent pay-down of past due payables, but not ongoing operating costs.
13. Per revised estimates based on further diligence done on ASES.
14. The currently estimated range of the impact of the loss of Act 154 is \$650 million to \$1,500 million. For illustrative purposes, the midpoint of this potential loss is included in the projections (with a half year impact assumed for 2018).
15. Included debt service payments related to GO, GDB, PBA, PFC, COFINA, PRIFA, UPR, PRCCDA, PRIDCO, GSA, PRIFA BANs, ERS, and HTA. PRIFA BANs are on accelerated schedule with excess cash flow sweeps as estimated by GDB. Note that the Krueger Report had netted the PRIFA BANs from the GDB net operating revenues and had embedded ERS debt service in the retirement shortfall estimate.
16. Accounts payable includes amounts owed to General Fund third parties, tax refunds, PRASA, PREPA, and police officer litigation. Excludes pay-downs by component units and HTA, which are embedded in the forecasts for those entities.
17. Amount required for GDB to meet its estimated minimum statutory liquidity requirement of \$350 million and the Commonwealth to have \$1.0 billion of total deposits on hand by the end of FY 2016 and \$1.5 billion by the end of FY 2017.
18. Identified inflows from entities outside the model (primarily SIF) that are used to cover certain General Fund related expenses in FY 2016. These expenses are included in the "General Fund Budget" line.
19. Ratio based on total revenues shown less Federal Transfers. Note that in the build to total revenues GDB net operating revenue includes certain deposit outflows. Additionally, PRIDCO revenues are embedded in the net operating deficit of component units, not in revenues, though its debt service is included in the consolidated interest and principal line items. Also note that any UPR revenues are not included as they are assumed to be offset with other UPR expenses consistent with the Krueger Report approach (appropriations to UPR are included as outflows in the model).

June 1987

Regulation or Deregulation of the Labour Market:  
Policy Regimes for the Recruitment and Dismissal of  
Employees in the Industrialised Countries

Michael Emerson

Internal Paper

The present paper was prepared while the author was a Fellow at the Center for International Affairs of Harvard University, in 1985-86, on leave from the Commission of the European Communities, Brussels. Opinions expressed in this paper are only attributable to the author, and not to any institution to which he is connected. The author is grateful to Professor R. Freeman of Harvard University and Professor P. Weiler of Harvard Law School for useful information on the United States, to Professor K. Sugeno of Harvard Law School similarly for information on Japan, and to G. Nerb of the Commission of the European Communities who was responsible for arranging the survey of European enterprises whose results are exploited in the text. The author is greatly indebted to Susan Young for her assistance.

**ABSTRACT**

In recent years there has been increasing interest among economists and policy-makers in the contrast between the comprehensive hiring and firing regulations in Western Europe and Japan and their total absence in the United States. The correlation between these differences and the low and high rates of employment growth of Western Europe and the United States respectively is also often thought to be significant, even if the Japanese case complicates such deductions. The present paper seeks in the first place to fill in for the serious lack of cross-country documentation of these employment regulations. It also sets out results from new surveys of how European employers perceive the impact of these laws. Finally, the paper considers policy options for European countries, the conclusion being that a fairly wide spread of moderate but specific policy reforms appears warranted with a view to helping improve the European employment situation. However, the option of replicating the United States model by total deregulation is rejected.

## **1. Introduction**

The main purpose of this paper is to provide a basis for assessing different policy options that exist in the realm of employment protection regulations and negotiated practices. In particular it is intended to help judge in what respects the policies of West European countries may warrant some reforms with a view to helping achieve a higher level of employment under socially acceptable conditions.

Among labour market regulations that are important for the employment performance of the economy, a large part fall under the colloquial heading of "hiring and firing rules". The main sub-headings here are:

- hiring rules favouring disadvantaged groups
- firing rules:
  - \* individual dismissal
  - \* collective dismissal
  - \* layoff and short-time work
- rules for contracts of limited duration:
  - \* temporary work
  - \* fixed-term contract
  - \* part-time work

There are important interdependencies between these items. Restrictive firing rules create demands for forms of contract that circumvent such rules, for example temporary and fixed-term work contracts. Once a policy orientation of security of job tenure is decided upon, this tends to lead to a more extensive body of regulations so as to limit the use of loop-holes. Employment protection is in this respect similar to trade protection, where the protection of one product leads to the protection of substitutes. This is what makes the difference in employment protection between the United States on the one hand and Europe and Japan on the other hand so categorical. The United States has basically an unregulated hiring and firing system, whereas European and Japanese labour law is comprehensive in these domains. In the absence of any regulation of individual or collective dismissals the United States abstains also from the further regulation of temporary or fixed-term work contracts.

In recent years the subject of these hiring and firing practices has, in economic and political debate, risen from being one of considerable technical obscurity to one of major controversy in relation to employment policy.

The main reason for this seems to lie in the apparent correlation between the differences in the policy regimes in Europe and the United States and these economies' respective employment records. United States employment growth has boomed, whereas Europe's employment has approximately stagnated. United States hiring and firing practices are completely unregulated by public law, whereas those of Europe are heavily regulated. Moreover, Europe's employment protection laws were in many cases accentuated in the early 'seventies, about at the time when the European unemployment problem was beginning to grow. Advocates of deregulation as a policy philosophy have seized upon this important example with enthusiasm. Analysts of the Euroscelerosis syndrome have often dwelt at length on the argument that overregulation of the labour market has made the European economy insufficiently adaptable to changing economic conditions. However, these familiar trans-Atlantic contrasts are too often much oversimplified. This is first of all illustrated by the recent emergence of an important trans-Pacific debate which complicates the trans-Atlantic debate. It is observed that Japan's hiring and firing practices have more in common with those of Europe than those of the United States. Yet Japan has avoided an unemployment problem. It is also argued by business school analysts of the weak competitive position of United States' manufacturing industry that the American tradition of free hiring and firing personnel policies may be part of the problem. By comparison, the Japanese tradition of employment security is associated with heavy investment in personnel training and is rewarded with qualities of loyalty and adaptability on the part of the labour force (see, for example Walton and Lawrence, 1985, Ouchi, 1981 and Thurow, 1985). Secondly, the unregulated regime in the United States is showing increasing evidence of instability in the sense of unpredictable but often very expensive awards by the courts in the case of private litigation over the conditions of dismissal (Flanagan, 1986 and Manes and Rosenbloom, 1985).

Meanwhile, economic theory has also contributed to the debate with attempts to bridge the gulf separating neo-classical, free market advocates and those who observe employment security and economic efficiency often going together. Efficiency wage theory and implicit contract

theory are concerned with reasons why real wage rigidity and employment security may in certain conditions be optimal for both employer and employee (see Akerloff, 1984 and Katz, 1986). Following on from this it has also been argued that where direct or indirect labour costs in the primary labour market are too high to permit a clearing of unemployment from the labour market, the optimal policy may lie in creating less costly employment conditions in a secondary labour market, rather than trying to undermine the wage level and employment security in the primary labour market (see Bulow and Summers). In this latter respect the United States and Japan have more in common, both having important elements of duality in their labour markets. Europe is more clearly the outsider on this account.

The debate over desirable employment protection practices is often conducted in extremely simplified and ideological terms. This is understandable in that the subject matter is complicated for any single country, and formidably so for a representative collection of countries. In addition the subject matter does not easily yield to quantification, unlike wage or social security costs. This weakness in political debate is also extremely unfortunate, because it results in an undue polarisation of positions and confrontation. In fact the subject matter breaks down into large number of eminently negotiable variables. The choice does not have to be between total deregulation on the one hand and the impossibility of dismissals on the other. A very fine graduation of many financial, procedural, and legal dispositions is in fact possible, and observable in the practices of the industrialised countries. It is to be hoped that a better informed debate will lead more easily to a consensus on the most suitable policies.

## **2. Principles Governing the Economic Impact of Hiring and Firing Regulations**

Regulations which raise directly or indirectly the costs of hiring and firing staff may be thought of as having the following six kinds of impact on the behaviour of the enterprise or employee.

- (i) Severance and procedural costs or delays in making dismissals will cause higher employment than otherwise in periods of weak demand, because the enterprise is deterred from reducing its payroll more quickly (see Gavin, 1986).
- (ii) However in normal or good demand conditions, and in the long-run, severance costs and delays will add an element of fixed costs to the wage cost of labour. This fixed cost will have some expected probability of being incurred, depending on the chances of the firm's

finding itself with excess labour at some future time, thus reducing the demand for labour and encouraging capital-for-labour substitution (see Gavin, 1986).

- (iii) Severance costs and procedural constraints will tend to segment the labour market between insiders with protected jobs versus outsiders trying to get jobs. This dampens competitive pressures on the wage level coming from the unemployed and therefore results in less employment than otherwise (see Lindbeck and Snower, 1984).
- (iv) However analyses of labour markets of the implicit contract school would point to employment protection provisions reducing risks for the employee and therefore causing a lower equilibrium wage level, and therefore higher employment (Gavin, 1986).
- (v) The lower probability of dismissal can have an adverse effect on work effort, with reduced possibilities for sanctioning shirking workers. This may also, by contamination, weaken the work effort and cooperation of other workers.
- (vi) However, increased job security is also interpreted in sociological literature as favouring loyalty and dedication of the employee to the interests of the firm (Akerloff, 1984).
- (vii) Employment security will also, through increasing the stability of the labour force, encourage the firm to invest in training and thereby upgrade the productivity of the worker (see Piore, 1986).
- (viii) Employment security may also increase the willingness of workers to accept technological change and internal job mobility and so also upgrade productivity (see Piore, 1986).

Controversy in debate about employment protection regulations is immediately understandable. Argument (i) is directly favourable to employment, argument (ii) is unfavourable. Argument (iii) is unfavourable to employment indirectly through wage effects, whereas argument (iv) is favourable. Argument (v) introduces unfavourable productivity effects but arguments (vi), (vii), and (viii) are favourable to productivity.

All of these arguments are extremely difficult to estimate quantitatively. In some cases, for example those concerning productivity, the importance of the argument will vary greatly between enterprises whose activities rely on team-work, high skills and changing technology; versus enterprises where jobs are simple to learn and to supervise. In the former category of enterprises job security provisions will be relatively more beneficial or less costly than in the second category.

One commendable attempt to formalise and quantify the impact of employment protection provisions is in a paper by Gavin (1986). He has set up a model for testing the employment cost and employment demand effects of severance rules, depending upon the values to be

placed on a number of key variables, including:

- the variability of labour demand (+)
- the trend growth rate of labour demand (-)
- the size of severance payments (+)
- the rate of natural wastage of labour force (retirement and other voluntary quits). (-)

The signs in brackets indicate the direction of impact. Thus a high trend growth of labour demand and high rate of natural wastage lower the probable effective costs of severance provisions. High variability of labour demand and high severance payments raise the probable cost of dismissals. All these variables enter into the equation because what is important in evaluating severance costs is not their simple magnitude (number of months of pay, depending upon length of service), but the expected probability that these costs may be incurred, and the expected probability of other procedural delays in the firm's ability to adjust the labour force to a level corresponding to product demand.

The elasticity of labour demand to wage costs also enters into the equation, notably for estimating employment impacts. Gavin's work has not gone far in relating the actual situation of different economies to the theoretical schema, but this could be done in principle. His sensitivity analysis suggests the possible employment effects to range from the trivial to the substantial.

Two particular points may be underlined at this stage:

- in periods of low demand, wholesale dismantling of employment protection laws might be expected to create more job losses than job creations. However, when demand is low, and expected to remain so in the future, severance costs and delays weigh particularly heavily on the firms' expected labour costs in judging whether to hire new recruits. Therefore, there may be a case, transitionally at least, for measures that retain the acquired rights of existing employees, but impose less heavy constraints on new recruits (ways of doing this are discussed further in the concluding chapter).

- in periods of high demand and buoyant expectations for future growth, employment protection provisions may be perceived by employers to be relatively costless, since voluntary quits would then provide an adequate cushion of flexibility in the size of the payroll. But as the economy moves into a depressed condition the perceived costs of the same laws become, as already suggested, much higher. In this respect the economic consequences of employment protection regulations are similar to unemployment benefits. When the economy is functioning at high activity rates, high levels of employment and social security seem entirely bearable for the economy. However, these features of the system also make the economy vulnerable to a prolonged economic down-turn. Employment protection costs rise in the same way as the social security bill rises. Both further dampen the demand for labour in a vicious circle movement. Such appears to have been the European experience in the period since 1973 (see also Blanchard et al, 1985 and Summers, 1986, and Blanchard and Summers, 1986, on these points.)

### **3. The Broad Picture in Inter-Country Comparisons**

Major differences in regimes for employment protection should show up in the rate of turnover of employment.

One available measure (from OECD, 1985) is the percentage of employees holding their jobs for less than two years. The following rank order has been noted in recent years:

Table 1: Rank order of countries by percentage of employees holding jobs for less than 2 years

1. Italy (1978)	13%
2. Belgium (1978)	18%
3. France (1978)	18%
4. Germany (1978)	19%
Luxembourg (1978)	19%
Japan (1978)	19%
European Community average	19%
7. Ireland (1979)	22%
8. United Kingdom (1979)	24%
9. Denmark (1978)	27%
10. Netherlands (1979)	28%
11. United States (1983)	39%

This measure immediately suggests some convenient rules of thumb. Short job tenure is on average in Europe about the same as in Japan, 19% of employees holding jobs for less than 2

years. In the United States short tenure is twice as frequent, with 39% of jobs held for under two years.

Within Europe, Germany and France find themselves about at the average, with Italy showing markedly fewer short-term jobs. The United Kingdom has more short-term jobs, and is situated together with Denmark and the Netherlands between the European average and the United States.

A second measure (also from OECD, 1985) is the annual turnover rate in the employment of enterprises, as measured by the average of the number of new recruits and separations (retirements, quits and dismissals) per 100 employees. In this case the following rank order emerges for the most recent year available (data is also given for a decade earlier, which indicates the trend):

Table 2: Percentage annual average of new recruits and separations

	<u>Recent data</u>		<u>Earlier data</u>		<u>Change</u>
1. Italy	(1982)	11%	(1971)	28%	-11
2. France	(1982)	14%	(1971)	20%	- 6
3. Sweden	(1984)	18%	(1974)	26%	- 8
4. Japan	(1983)	18%	(1971)	25%	- 7
European Community average		18%		27%	- 9
5. United Kingdom	(1984)	20%	(1971)	30%	-10
6. Germany	(1982)	25%	(1973)	33%	- 8
7. Finland	(1983)	35%	(1972)	38%	- 3
8. United States	(1981)	40%	(1971)	48%	- 8

Although these data concern only manufacturing industries (except for Germany and Finland where they cover the whole economy) a similar story emerges. Job turnover averages 18% per annum in Europe, as in Japan, whereas it is about twice as high in the United States (40%). Within Europe, Italy is again conspicuous for the extremely low degree of labour turnover.

A feature common to all countries, however, is the reduction in the rapidity of labour turnover over the course of the decade covered in the data. For the extent of this reduction, Italy again heads the rank order, followed by the United Kingdom.

Another indicator of the severity or otherwise of policies towards dismissals is found in surveys of unemployed persons which distinguish between various reasons for entering unemployment (dismissal, resignation, new entrants into the labour force, etc.). In the following

data, a low percentage of dismissals suggests relatively severe regulations or practices restraining dismissals, whereas a high percentage suggests a liberal dismissals regime.

Table 3: Percentage of unemployed, 1981, who became so because of dismissal or redundancy

Italy	8%
Greece	37%
France	41%
European Community average	43%
United States	52%
United Kingdom	56%
Netherlands	58%
Denmark	83%

Source: for European countries Eurostat, 1983.

For United States: Bureau of Labor Statistics Monthly Labor Review. The U.S. figure includes 16% on lay-off.

The United States ranks higher than the European Community on average in the extent the unemployed became so because of dismissal, but by a smaller margin than the preceding two indicators of labour market flexibility. (It is possible that the data in Table 3 are not too comparable, the United States unemployed showing a particularly high percentage of re-entrants into the labour market which may be due to the short duration of unemployment benefits. However, cyclical fluctuations in the percentage of dismissals among the unemployed are not very high, ranging in the 'eighties between 50 and 59% in the United States.)

As between European countries, these figures confirm other indicators of the extreme difficulty of making dismissals in Italy; as also the finding of Germany and France in the middle of the European range, with the United Kingdom, the Netherlands and Denmark at the liberal end.

The high dismissals figure for Denmark deserves special note, not only because of its extreme level. Denmark did not participate in the E.C.'s survey of employers, and so is not included in a number of tabulations below. However, the above finding from Eurostat's labour force sample survey is consistent with the view that Denmark's legislation on dismissals is the most liberal in the E.C. It is also the case in the period 1983 to 1985 that Denmark's employment level has grown faster than in any other E.C. country, suggesting a high elasticity of employment to changing economic conditions when the regulation of dismissals is liberal.

As regards Italy's very low dismissals figure, the counterpart is found in the very high percentage (78%) of Italy's unemployed who are first job seekers, compared to 22% for the

European Community on average and 13% for the United States. The high percentage of first job seekers reflects a very acute youth unemployment problem. This illustrates how employment protection law may affect the trade-off of interests between different sections of the Community.

In order to obtain more detailed information on the perceptions of employers as regards the employment impact of these and other regulations, the Commission of the European Communities undertook in 1985 a detailed harmonised survey of 50,000 companies in 9 EC countries (C.E.C., 1986). The results indicated the following rank order of countries according to the importance enterprises attached to "insufficient flexibility in hiring and shedding labour as reason for not employing more staff":

Table 4: Percentage of firms considering insufficient flexibility in hiring and shedding rules to be an important obstacle to employing more staff

1. Italy	83%
2. France	81%
3. Belgium	75%
4. Greece	67%
5. Ireland	68%
European Community average	60%
6. Luxembourg	56%
7. Germany	56%
8. Netherlands	51%
9. United Kingdom	26%

These findings are again broadly consistent with those already reported from labour turnover data. Germany is close to the European average. Italy is the country where the regulatory burden is most widely considered to be an important impediment to employment. The United Kingdom is at the other extreme where only a minority of firms consider hiring and firing regulations to represent an important obstacle to employment. France, Belgium and Greece are also reported by their industrialists to have problematic regulations from the point of view of increasing employment. French regulations were subsequently eased in 1986.

Further use will be made of this survey below on more detailed aspects of hiring and firing regulations, as also of another survey by the International Organisation of Employers (IOE, 1985).

Opinion surveys of this kind are sometimes considered to be of questionable scientific value, especially where they touch on policy issues, as in these cases. The replies may be biased

by the political interests of respondents, so the criticism may go. Some reassurance against this concern, however, is suggested by the fairly good correspondence between the statistics on labour turnover quoted above, and the summary results from the Commission's survey.

#### 4. Rules of Recruitment

It is normally the case that employers are free to decide whom they hire. The regulation of recruitment largely concerns under what conditions, or how they are recruited. However there are some exceptions to the normal freedom over whom to recruit.

The employment of black and Hispanic people and women has been favoured by affirmative action legislation in the United States since 1965, when federal contractors were required by an Executive Order to make "good faith efforts" to employ minorities. Enterprises were required to compare their employment record for these groups with the regional average. Companies with poorer records risked the sanction of being debarred from government contracts. Only 30 such cases are known to have been treated this way, but many more may have been influenced by the threat. 50,000 companies, employing 23 million workers have been affected. Leonard (1985) has conducted research on the difference in employment performance between this group of enterprises and the rest of the economy. His findings were that over the period 1974 to 1980 the growth rate of employment for this group of companies was 3.8% faster for black men, 7.9% faster for black women, 2.8% faster for white women and 12.3% faster for women. For white men, the growth was 1.2% slower. However, in 1986 the Reagan administration decided to amend this legislation, making the target indicators voluntary rather than obligatory. (New York Times, January 11, 1986).

In Europe and Japan there is no comparable legislation, although the relatively unfavourable employment situation of ethnic minorities in several European countries is creating an increasingly similar situation to that of racial minorities in the United States. Anti-discrimination legislation exists in European countries, including the United Kingdom.

Only one European country, Italy, has attempted to regulate precisely whom is to be recruited. The public employment service there implements a law which requires companies seeking to hire workers to follow a rank ordering of candidates determined administratively by the public employment service. This so-called "numerical" system in principle lists candidates by order of merit according to some social criteria, like the size of the person's family

commitments and the length of unemployment spell. The system is widely criticised by employers, and its considerable impracticability has led to its limitation in various ways (jobs requiring special skills are excluded, as are firms with less than 5 employees, the recruitment of up to 10% of workers in large firms, the recruitment of relatives, etc). In 1985, the government decided to allow firms to recruit young people for apprenticeships and otherwise 50% of their needs freely, leaving only the remainder determined by the numerical rank order. These exceptions relax the law, while adding, however, to the complexity of the regulations and administrative practice. The external observer of the Italian labour market may be inclined to regard these remaining constraints in the system as archaic, bureaucratic anomalies, due for scrapping. Since this regulation was introduced, there have been major developments in many other features of the Italian social security system. The case there may have been at some stage for using recruitment regulations of this type an instrument of social policy has surely been greatly weakened.

An issue of concern to more European countries is the performance of public employment offices, and their monopoly status in most countries. The business community is often very critical of the quality of help effectively given by public employment agencies. For example, a recent government survey in Denmark reported that only 10% of vacancies were filled by the public employment service, and that many employers and job seekers had virtually given up using it. Why employment agencies should be a monopoly of the public sector is not evident. In any case the public agencies only enjoy a monopoly in a narrow sense, since a large amount of recruitment is done by other means, for example, direct advertising in the press. In Italy regulations are again more stringent than elsewhere. An employment contract made directly with an individual is subject to annulment by the law if it is not ratified by being put, ex-post, through the mediation of the public agency. Italy, alone with Sweden, prohibits private temporary work agencies (see further below). The demand for temporary labour in Italy has therefore to be channelled through the public agencies, where the procedures mesh with the "numerical" system, described above, of rank-ordered candidates. These provisions have encouraged the expansion of sub-contracting work to small enterprises, including some 1 1/2 million home-workers who can classify themselves as self-employed and escape the various official regulations.

Alone among European countries, the United Kingdom permits licensed private employment agencies to function alongside the public employment services.

In the United States there is no regulation of private employment agencies, or other methods of recruitment. A recent sample survey of manufacturing enterprises showed the following numbers of companies to be using the various means or channels of recruitment indicated:

trade union	16
public employment agencies	77
private employment agencies	78
advertising in media	85
recommendation	84
schools, colleges	171

Employment of handicapped persons. This is the sole category of persons which is generally supported in Europe by affirmative regulations (see Commission of the European Communities, 1985). Germany's employment policies towards handicapped persons may be described as a model case. Enterprises with over 15 employees are required to take on handicapped persons to the extent of a 6% quota. Companies not fulfilling the quota pay a fine of DM 100 per month per head (about 20% of the average wage in manufacturing), and companies more than fulfilling the quota benefit from a subsidy from a fund into which the fines are paid.

The other large European countries also set quotas (France 10%, United Kingdom 3%, Italy 15%). France also has a fine and subsidy system as in Germany. The United Kingdom does not apply financial sanctions, but modulates hiring and firing rules for companies not fulfilling the quota. Italy's quota regime is a simple regulatory requirement.

The smaller European countries have a mix of regimes, some applying quotas some making no quantified requirement.

The Italian policy rules appear to be the most demanding and rigid. The Italian quota of 15% is exceptionally high - a surprisingly high 19% of the population are registered as disabled or handicapped. Less surprisingly, Italy only achieves an actual disabled employment rate of 4.5%, which is about the same as for Germany (4.8% - 1980 figures). The Italian regulation, according to anecdotal information, acts a stimulus to keeping small enterprises just below the maximum size that escapes the regulation. A more flexible regime is to apply fines and

subsidies around the quota as in the German case. In this way the unevenness in local or sectional labour supply and demand conditions for handicapped person can be smoothed out.

The United States has an Executive Order recommending affirmative action in favour of handicapped persons, but there is no compulsion or enforcement, and so the measure may be effectively disregarded.

**Table 5: Employment regulations for handicapped person**

United States	no obligations
France	10% quota for firms with over 10 employees; fines for underfulfillment, subsidies for recruitment
Germany	6% quota for firms with over 15 employees; fines of DM 150 per month for underfulfillment, subsidies for overfulfillment
United Kingdom	3% quota for firms with over 20 employees; limitations on freedom to hire able-bodied persons for underfulfillment and restrictions on dismissal of handicapped persons
Italy	15% quota for firms with over 35 employees
Belgium	no mandatory quotas
Netherlands	3-7% quota may be prescribed by the Social Insurance Council if firms efforts are judged insufficient
Sweden	no mandatory quotas
Denmark	no mandatory quotas
Norway	no mandatory quotas
Ireland	3% quota, mandatory only in public sector
Greece	7% quota for handicapped persons and war veterans for firms with 100 employees or more

Source: Commission of the European Communities (1983), other national sources.

### **5. Systems for Individual Dismissals**

In Europe the rules of individual dismissal often distinguish between cases involving criminal acts and gross misconduct on the one hand, and cases based on economic conditions such as redundancy and the professional suitability or qualifications of the employee. The former category generally allows summary dismissal without compensation. The latter category

generally involves statutory procedures, periods of notice, and minimum amounts of financial compensation. (See I.R.E., 1984, and E.I.R.R., 1985, 1986.)

The procedures for the dismissals based on economic and professional reasons are often set out in extensive detail.

Procedures differ in many details among European countries. One key issue is how far the employer's prerogative to decide on his employment decisions is reduced by the role of third parties - trade unions, works councils, government or the courts. It is frequent for one or other of these third parties to possess considerable discretionary powers. In the Netherlands the government's labour service must approve the decision. In Germany, Italy and Sweden the works council or trade unions must be consulted. In France this was the case until 1986 when the new government repealed this requirement. In Germany if the works council does not agree, the dismissed employee may take the case to the labour court, where procedures are sometimes very long and drawn out (up to 5 years) during which time the employee must be retained on full pay. This is the normal procedure. However there are cases in which the works council's agreement must be obtained, failing which the employer must go to the labour court. In Italy appeal to the courts is likely to see the judiciary take such a favourable view of the employee's social or family problems that dismissal is commonly judged to be practically impossible. In Sweden the trade union has a legal role in determining in the first instance whether a dismissal is unreasonable: the employer can appeal to the courts against an unfavourable position but will rarely win. Other European countries with onerous dismissals procedures are Portugal, Spain, Norway, Belgium and Ireland.

The Japanese system for "regular" employees is equivalent to these European systems in restraining dismissals. Case-law establishes that dismissal for disciplinary reasons should not be overly severe. For example, in a key case, a news broadcaster for the early morning news twice overslept. He was dismissed but through an appeal to the courts he was reinstated (see *Shioda V. Kochi Broadcasting Co.*, 1977 in Sugeno, 1986). Dismissal for economic reasons has to be very strongly justified (see also under collective redundancies).

The United States, by contrast, has no general legislation governing of dismissals. Traditionally, since the 19th century, employers have been free to terminate contracts of employment "at will" for any reason, subject only to limitations established in the individual's

contract of employment or a collective bargaining agreement. Such contracts and agreements may fix periods of notice and amounts of compensation, but this is not required by law. Recently, however, the courts in many states have been moving away somewhat from the ultra-free firing model, requiring that dismissals be justified on reasonable grounds. A few states still adhere to the 19th century presumption, one state court even affirming in 1956 that an employer can freely fire an employee "for good cause, or bad cause, or no cause at all". However, the trend is against this view. Twenty-nine states recognise exceptions to the at-will doctrine. The number of wrongful termination law suits has increased dramatically in recent years - with 10 fold increases each year. Legal experts consider that this trend will continue as lawyers find such cases easy to prosecute and promise potentially staggering awards. Manes and Rosenbloom of Harvard Law School conclude their detailed study (1985) in the following terms:

"Corporations and businesses facing such large damage claims are looking for wages of limiting their risks in the "Russian roulette" of employee law suits. Legislatures are considering proposals that would change the entire termination at-will presumption. The courts are struggling towards a more precise definition of what constitutes a wrongful termination... this area of law is an muddled and confusing as it is significant... The conclusion seems unavoidable that legislation is required to balance the interests of all concerned".

Flanagan (1986) reports an analysis of 102 cases in Californian courts of wrongful discharge between 1982 and 1986. Three-quarters of the plaintiffs' cases were upheld with awards for general damages averaging \$344,000, and awards for punitive damages \$557,000. Thus the costs of "freedom" to dismiss staff in the United States can be very high compared to statutory provisions in Europe. In fact the United States paradigm of free hiring and firing and non-regulation appears in practice to have become unstable, and ultimately unsustainable. While federal legislation appears highly unlikely for the time being, it is not inconceivable that individual states may provide a clearer and more settled framework for the private sector to follow.

The United Kingdom's regime is worth noting as one which is regulated in order to protect against unfair dismissal but nonetheless gives the employer a considerable prerogative to dismiss redundant or poorly adapted staff, with moderate amounts of financial compensation.

However, neither government or trade union approval is required, and the arbitration and tribunal system for dealing with complaints over unfair dismissal is expeditious and fairly sympathetic to the employer's management concerns. Only one-third of complaints reaching the tribunal stage are upheld, and most cases are disposed of within three months of submission to the courts (see Annex 3 for detail). In 1985 the rules were relaxed by raising the minimum period of service required before the tribunal system for unfair dismissal could be used from 1 to 2 years. Ireland has a tribunal system that appears to be comparable with the British system (in 1983 about one-third of cases heard in Ireland were found in favour of the employee charging unfair dismissal).

#### **6. Rules for Collective Redundancies**

As in the case of individual dismissals, the conditions for collective redundancies are regulated in Europe by law. An EC Directive of 1975 stipulates some minimum conditions, such as 30 days of prenotification to be given to workers representatives. EC countries have since adapted their laws as necessary. Similar laws have generally been introduced governing plant closures. (See I.R.E., 1984, and E.I.R.R., 1985, 1986.)

In the United States, by contrast, there is no general law, any legal requirements depending upon the terms of collective bargains (see Harrison, 1984). In 1980 only 15% of collective bargains contained prenotification procedures. In 1981 a Supreme Court decision ruled that a company may close a plant without notification or bargaining with the trade union, unless the collective bargaining contract contains a "preservation of work" clause. In recent years there has been some publicity given to agreements in the automobile and meat-packing sectors in which job-security provisions were granted in exchange for concessions on work practices or pay. However, a survey of such contracts agreed in 1982 suggests that the typical deal saw withdrawal of a planned closure or lay-off against concessions over wage levels rather than commitments to a different system governing job tenure. Moreover, a study by Capelli and McKersie shows that most of these enterprises in fact soon closed down the plants in question.

In Europe the restraints imposed upon management are often analogous to those for individual dismissals. Prenotification delays are added to the specific notice periods owed to individuals as a function of years of service. Trade union consultation is frequently required,

and government authorisation needed in some cases (Netherlands, Greece, Spain, Portugal and, until 1986, France). The effective importance of the intervention of the government is hard to assess. On the one hand the enterprise may see the government's powers of approval or refusal as limiting an important management prerogative. However, the enterprise unable to adjust its labour force to economic necessities will go bankrupt, and the labour ministry will hardly be interested in provoking this. The government's authorisation may, in some cases, amount to little more than registering an event, and putting pressure on the enterprise to show that it considered alternative solutions. In Spain the intervention of the labour ministry amounts more to deliberating on whether dismissals are to be classified as fair or unfair than to preventing dismissals; however, compensation for unfair dismissal is extremely high (see below). In the Netherlands, the government in 1985 decided to limit to four-to-six weeks the maximum time its agencies could take to deliberate on proposed dismissals. In France, too, the government promised in 1985 to shorten delays in which the Administration decides on proposed dismissals (it agreed to 90% of requests in recent years). In 1986 the new government scrapped the need for administrative approval.

In Europe, the cost of compensation to redundant personnel is usually expressed as a function of years of service, but is often a complicated formula. The range for blue collar workers is between 1/2 week's pay per year of service (France), about 1 week (Netherlands, United Kingdom), rising to as much as 4 weeks in Spain. For Germany, Denmark, Norway and Finland the law leaves the amount open to negotiation. Compensation for unfair dismissal is often much higher, 5 months minimum in Italy, 6 months minimum in Belgium, 16-32 months in Sweden and up to 42 months in Spain. The Belgian government in 1985 significantly reduced the scale for compensation awards.

In the United Kingdom the relatively modest cost of redundancies are also 35% subsidised by public funds for enterprises with less than 10 employees. This makes the British regulations the lightest in Europe except perhaps for Denmark and Finland which leave redundancy compensation to be fixed by contract or collective bargain.

In Japan the lifetime employment tradition in large enterprises is buttressed strongly by the requirements of case law decided by the lower courts, although general legislation makes no requirement other than 30 days notice (see Inagami, 1984). Case laws makes it clear that an

extensive set of preconditions have to be met before redundancies can be admitted (see *Toyo Sanso K.K. v. Koji Shimazaki et al*, in Sugeno, 1986). The objective need to make redundancies for economic reasons has been established, and a specific list of alternative courses of action has to be exhausted such as recourse to internal transfer of surplus staff, work-sharing and part-time practices, national wastage through non-replacement of retiring personnel, dismissal of temporary workers and calls for voluntary early retirement. Trade unions have also to be consulted. In practice the possibilities for internal deployment of manpower in large firms and the other techniques are such as to make redundancies a rare event. However, smaller firms make more recourse to these legal possibilities for dismissal. The lump-sum payments made to dismissed staff are very large, but these can be confused with the system of retirement gratuities. On average on retirement a Japanese worker receives about 43 months pay as a gratuity, but 55% of firms have no private pension scheme. A dismissed employee receives a similarly important sum, but this implicitly contains quasi-retirement benefits.

The International Organisation of Employers in 1985 (I.O.E., 1985) reported how each country's employers organisation assessed the severity of the rules restraining the termination of employment contracts.

Table 6: Importance of obstacles to the termination of employment contracts

1. Obstacles are fundamental

France  
Germany  
Italy  
Netherlands  
Portugal  
Spain

2. Obstacles are serious

Austria  
Belgium  
Ireland  
Norway  
Sweden

3. Obstacles are minor

Denmark  
Finland

4. Obstacles are insignificant

United Kingdom

According to the Commission's survey in 1985 (C.E.C., 1986) European Community countries assessed the possible employment impact of shorter periods of notice for redundancies and simpler legal procedures in the following rank order:

**Table 7: Percentage of firms judging that there would be a positive employment impact from shorter periods of notice for redundancies and simpler legal procedures**

1.	Italy	88%
2.	Greece	76%
3.	Belgium	74%
4.	Germany	63%
	European Community average	58%
5.	Luxemburg	54%
6.	France	48%
7.	Netherlands	47%
8.	Ireland	35%
9.	United Kingdom	28%

As regards the question whether a reduction in redundancy payments would have a positive employment impact, the Commission survey (C.E.C., 1986) showed the following rank-order:

**Table 8: Percentage of firms considering that a reduction in redundancy payments would have a positive employment impact**

1.	Italy	78%
2.	Belgium	63%
3.	Greece	62%
4.	Luxemburg	52%
5.	Germany	46%
	European Community average	42%
6.	Ireland	33%
7.	United Kingdom	23%
8.	France	22%
9.	Netherlands	12%

It is notable that the financial cost of redundancy payments was in all countries considered to be a less important problem than the length of notice periods and the difficulty of legal procedures. This is particularly so in the case of France (indeed, as noted earlier, French compensation payments are among the lowest, but procedures have been onerous).

This general classification accords well with the main regime features described above. The countries in the first category of the I.O.E. survey (France, Germany, Italy, Netherlands, Portugal, Spain) all featured in 1985 the intervention of trade unions, works councils or government in the procedures and authorisation of dismissals (collective or individual or both). At the other end of the scale are countries which have no governmental interference in the decision process and where the amounts of compensation are not determined by law (Denmark, Finland) or are low (United Kingdom).

#### **7. Lay-Offs or Short-Time Working**

A lay-off is an arrangement whereby a worker is required to stop working for a temporary period, but without termination of the employment contract. The worker is usually not paid wages by the employer, but receives compensation from public funds. Alternatively employees may be required to work on a short-time basis, for example, two to three days per week. As techniques adjusting labour costs in the light of cyclical demand movements, lay-offs and short-time are in principle more flexible than recruitment and dismissal on and off.

Regimes facilitating total lay-off of personnel are not widespread. The possibility to lay-off workers completely exists only in the United States and Italy among the larger industrialised countries where the practice is widely used. Some smaller European countries also have lay-off arrangements (Belgium, Norway) but short-time working is the more general alternative in Europe (EIRR, 1983). The number of workers laid-off in the United States tended to fluctuate between 1 to 2 million in the period 1960 to 1981, from cyclical peak to trough (BLS, 1983). Laid-off workers benefit from the same compensation as in the case of unemployment.

The only European country to have a somewhat comparable regime is Italy where the CIG (Cassa Integrazione Guadanzi - "complementary integration fund") provides compensation of 80% of prior earnings. The original intention of the CIG was that it allow for cyclical flexibility in the labour costs of industrial employers - thus close to the United States system. However it gradually became a shadow unemployment compensation scheme that offered often indefinite benefits of much higher amount than the official unemployment scheme. For example, in March 1986 it was announced that FIAT was going to reemploy about 6,000 workers who had been laid-off for nearly six years. The CIG has in effect given cost flexibility to employers, but has at the same time frozen a sizeable fraction of the industrial labour force in inactive situations, except that reports of beneficiaries working the black economy are legion. Since the CIG was much expanded in the 1970s labour turnover in industry has dropped by one half (see D'Apice and Del Boza, 1985).

The more common type of regime in Europe is short-time working or "partial unemployment." This is the case in France, Germany, the United Kingdom, Spain and the Benelux countries. Typically the worker is compensated as a percentage of lost earnings at the level of unemployment benefits or somewhat less.

Perceptions of competitive disadvantage suffered by European companies compared with the United States are illustrated by the example of competition between Boeing and Airbus in the aircraft industry. Boeing has in the last decade resorted to some massive lay-offs and recalls in order to respond rapidly to changing demand conditions. Airbus, manufacturing in France, Germany, the United Kingdom and Spain, has much greater difficulty in adjusting to peaks in demand. It has to take a longer-term view of demand prospects in recruiting, and typically is more cautious in taking on extra staff. As a result delivery delays are often twice as long for Airbus, compared to Boeing. (See The Sunday Times, 2 March 1986, "Airbus Flies into Battle.")

Table 9: Lay-off or short-time working regimes

United States	Lay-off regime, compensation as for unemployment.
France	Compensation for reduced working time up to total of 50% of gross hourly earnings, up to 600 hours of reduced time per year.
Germany	Compensation for reduced working time up to 68% of net earnings for up to 24 months; 1/3 of employees must be idle for over 10% of working time.
Italy	Compensation of up to 80% of gross earnings paid by the Cassa Integrazione Guadanzi for up to 40 hours per week, ordinarily for up to a year, but in practice indefinitely in the case of recognized reorganisations. In 1987 government proposes to limit indemnities to 3 years.
United Kingdom	No provisions under public law or social security; only as may be negotiated in collective bargains.
Belgium	Compensation in line with unemployment benefits is paid for up to 4 weeks of lay-off or 3 months of part-time work, on condition that full time working then resumes.
Netherlands	Compensation in line with unemployment benefits is paid for up to 6 weeks for reduced working time.
Sweden	Compensation in line with normal pay for up to 30 days a year, the employer being reimbursed at most for 23 days.
Norway	Compensation in line with unemployment benefits is paid for up to 40 weeks in respect of complete workless days.
Switzerland	Compensation in line with unemployment benefits.
Greece	Compensation of 50% of normal pay for up to 3 months per year.
Spain	Compensation in line with unemployment benefits is paid for up to 18 months in respect of reduced working time.

## **8. Temporary Work and Fixed-Term Employment Contracts**

Temporary work tends to be of two types:

(i) the supply by specialised temporary work agencies of personnel to another company for short periods, in which the workers are legally employed by the agency;

(ii) direct employment on contract for a short and fixed time duration, such as seasonal jobs in agriculture and tourism.

Trade unions are usually strongly opposed to such practices and often argue that they should be outlawed. They see dangers of competition in the labour market from groups that will have weak market power, of abuse by employers of their market power in relation to unorganised labour, and a way of circumventing employment protection laws. Employers point to the need to assure the supply of labour for seasonal or other irregular demands. Individual countries seem in their policies towards temporary work to typify their broader tendencies on questions of labour market rigidity or flexibility (see Albeda (1985) for a detailed account).

Thus in the United States there is no regulation or licensing requirement at all of temporary work companies or individual employment. The numbers of persons employed in this way increased very fast in the years since 1982 (see Carey and Hazelbaker, 1986). According to Albeda (1985) some 500 private companies compete in supplying temporary workers, amounting 1 1/2 to 3 million people depending upon estimates (2-4% of the work force). Such personnel is covered by general labour law (including the minimum wage) and social security. However, the conditions of employment usually exclude fringe benefits such as holidays, holiday pay, and private pension and health insurance benefits; the latter are of course particularly important in the United States since public health insurance is not generally available. The workers can normally be dismissed without notice, compensation or recourse. The only effective restrictions on temporary work come from collective bargains where for given firms trade unions may negotiate a commitment from the firm that they abstain from this market.

In Japan, the temporary work market provides an important element of duality alongside the lifetime employment system (see Hobara, 1985). About 10% of non-agricultural employees are temporary or day labourers, with twice as many women as men in this category. Temporary employment provides a margin of employment flexibility that enterprises want, and the lifetime employment system obviously cannot provide. The pool of temporary workers tends to be those who have quit other jobs and failed to obtain 'regular' recruitment after graduating from school. Directly employed temporary workers are typically subject to special employment rules, notably allowing for termination. National health and pension coverage is typically provided for, but there may be exemptions from unemployment insurance for daily and seasonal workers. Usually temporary workers are excluded from trade union membership.

European regimes have diverged in the extent of their regulatory restriction of temporary work, although the EC Commission has proposed a directive to assure a degree of harmonisation (this proposed directive remains unpassed).

Table 10: Regulation of private sector temporary work agencies

United States	unregulated
Japan	regulated, restricted to specified activities
France	restricted under licensing system
Germany	restricted under licensing system
Italy	prohibited; law strongly prefers permanent employment contracts
United Kingdom	regulated under licensing system
Belgium	restricted under licensing system
Netherlands	restricted under licensing system
Denmark	restricted under licensing system (only permitted in business and office branches)
Norway	restricted under licensing system (only permitted in business and office branches)
Sweden	prohibited; direct temporary employment severely restricted since 1974.
Switzerland	unregulated
Ireland	regulated under licensing system
Greece	restricted to specific activities

**Note:** Temporary work companies hire personnel to a third company for limited periods of time. Direct temporary employment involves only employer and employee in a contract of fixed duration.

**Source:** Albeda (1978).

Italy and Sweden are at the most restrictive end of the regulatory spectrum in Europe. Both countries prohibit private temporary work agencies, and both severely restrict direct employment on the basis of non-permanent contracts. Sweden, however, had freedom of direct temporary employment until 1974 when restrictive legislation was introduced. Both countries apparently have substantial black or grey markets in temporary employment. In Sweden the 1976 "right-to-veto" legislation gave trade unions the power to object to temporary work contracts where "improper practice was taken to be involved" but not necessarily proved (Kennedy, 1984).

A group of other European countries legislated in the period 1970 to 1976 to regulate and restrict temporary work companies quite strictly: Germany, France, Belgium, Netherlands and Denmark. These countries operate licensing systems for such companies imposing not only obvious requirements such as social security coverage but also a variety of restrictions on the type of work or length of contract permitted. Generally trade unions press for total prohibition of temporary employment, and the legislation that has emerged reflects a compromise between the desire of trade unions to prohibit such agencies and that of employers to have freedom to satisfy special employment needs.

In France, the Socialist government in 1982 tightened the regulations governing temporary work, following a rapid expansion of the number of such workers since 1975. The uses of such labour was restricted to specific situations, such as to fill in for absence of a permanent employee. An "insecurity bonus" of 15% had to be paid to staff at the end of the contract. Trade unions were given statutory rights to institute legal proceedings against abusive use of temporary work. As a result it was estimated that a 30% reduction in the number of employees of this type resulted in 1983. In 1986, however, restrictions on temporary work were eased.

In the United Kingdom direct temporary employment (casual labour) has been progressively reduced under legislation adopted in 1975 and 1976 of the Labour government of the day.

The law on fixed-term contracts in Europe tends to be analogous to that set for temporary workers. Typically, regulations define restrictive conditions under which such contracts may be offered (seasonal needs, to replace a permanent employee's temporary absence, etc), and the maximum duration and possibilities for extension of the contract. The 1970s saw in Europe

widespread legislation making these regulations more comprehensive or restrictive. The France governments legislation of 1982 appears to be the last example of the period of tightening regulations. Since then several countries have opened wider opportunities for fixed-term contracts as a way of easing the burden of severe restraints or dismissals. In Germany legislation in 1985 extended the maximum duration of fixed term contracts from 6 to 18 months, also removing the need for any particular justification of such contracts. Spain adopted similar measures already in 1984. Italy in 1984 opened new possibilities to offer fixed term contracts to young people. France in 1986 reversed the restrictions introduced earlier.

Table 11: Regulation fixed-term contracts

United States	unregulated
Japan	permitted, but automatic renewal converts into permanent contract
France	'82 law tightened criteria to jobs only manifestly of a temporary nature; '86 law liberalises, extends duration to 24 months
Germany	'85 law extends (temporarily until 1990) duration from 6 to 18 months, with no justification required
Italy	permitted only for seasonal or exceptional needs
United Kingdom	unregulated, freedom to make fixed-term contracts at will
Netherlands	permitted, but if extended subsequent dismissal requires official permission
Switzerland	unregulated
Sweden	'82 law allows 6 month probationary period, and some special (seasonal) work, including up to 6 months employment in 2 years for peak-load work periods
Finland	permitted only when motivated by temporary nature of work, or traineeship
Norway	illegal, except for naturally limited jobs
Spain	'84 law allows 6 mth - 3 yr contract for new firms
Greece	permitted, but if repeated contract becomes permanent
Portugal	'75 law allows 6 mth to 3 yr contracts upon evidence of temporary nature of work.

Source: I.R.E. and E.I.R.R. (various issues).

The survey of the International Organisation of Employers (I.O.E., 1985) indicated that temporary work regulations were judged as follows:

**Table 12: Importance of regulatory constraints of temporary work according to employers' organisations**

<b>1. Fundamental Constraints:</b>	<b>Belgium Italy Spain</b>
<b>2. Serious Constraints:</b>	<b>France Germany Netherlands Sweden</b>
<b>3. Minor or Insignificant Constraints:</b>	<b>Austria Denmark Finland Ireland Luxembourg Norway Portugal Switzerland United Kingdom</b>

Source: I.O.E. (1985)

The same survey reported the following opinions as regards regulation of fixed-term contracts:

**Table 13: Importance of regulatory constraints of fixed-term employment contracts according to employers' organisations**

<b>1. Fundamental Constraints:</b>	<b>Belgium Italy Netherlands</b>
<b>2. Serious Constraints:</b>	<b>France Germany Luxembourg Sweden</b>
<b>3. Minor or Insignificant Constraints:</b>	<b>Austria Denmark Finland Ireland Norway Portugal Spain Switzerland United Kingdom</b>

Among European Community countries, the Commission's survey of 1985 (C.E.C., 1986) indicated the following rank ordering according to the percentage of firms that would expect a positive employment impact from measures facilitating temporary contracts (fixed term, interim work, etc):

Table 14: Percentages of firms expecting a positive employment impact from measures facilitating temporary contracts

1.	Germany	74%
2.	Luxembourg	69%
3.	Italy	63%
4.	Belgium	63%
	European Community average	55%
5.	France	53%
6.	Greece	50%
7.	Ireland	47%
8.	Netherlands	32%
9.	United Kingdom	27%

### 9. Part-Time Work

The extent of part-time work in the EC on average and in the United States is not, in the aggregate, very different. Some 13 million people were in 1983 working part-time in the EC, compared to 15 million in the United States in 1985. This amounts to 12 and 13% of the labour force respectively. However, the range is quite wide within Europe: 7% in Italy, 9% in France and Germany, 20% in the United Kingdom and even higher in Scandinavia. Japan's labour force includes 6 1/2% of part-time workers, a share that is rising. As Dreze (1986) has shown, a high share of part-time employment tends to in Europe to be associated with high total labour force participation rates. This reflects the widespread preference of second workers in the family to be employed only part-time. There is on both sides of the Atlantic a preponderance of part-time work among women in the 25 to 50 age bracket.

The main difference in the structure of part-time work between the European average and the United States is seen in greater number of young people (three times as many) who work part-time in the United States compared to Europe. In the United States part-time work among high school and university students is widespread and encouraged, whereas in Europe it is much less so. In the United States a little over one quarter of those in the age bracket 16 to 24 years old who are not in full-time labour force have part-time jobs.

The policy regimes for part-time work tend to be quite different as between Europe and the United States.

In Europe the broad thrust of policy has been to provide equality under the law for part and full-time employment (see EIRR, 1985). This principally means assurance of equal basic pay per hour for comparable jobs, equal rights under employment protection law, and the requirement of social security coverage. Social security contributions will normally be proportional to salary, but in some countries the regime is not so neutral or simple. Some countries impose substantial minimum social security contributions (e.g. Belgium) which may mean very heavy taxes on short lengths of working time. Others allow freedom from contributions for work under a certain level. In the United Kingdom this limit is expressed at L35.5 of weekly earnings, which is about one quarter of the average earnings for a full week's work. The United Kingdom also exonerates jobs of under 8 hours per week from the provisions of employment protection law (or 8 to 16 hours if the employee has less than 5 years of service). The Government is proposing currently to extend these thresholds. It is notable that part-time employment benefitting from these provisions has been the main growth element in aggregate employment in the United Kingdom in recent years.

In the United States there is no legislation governing part-time employment. Such jobs are invariably subject to free hiring and firing conditions. Social security contributions are paid at normal percentage rates. More significant is the fact that part-time jobs will often not benefit from fringe benefits such as private medical insurance and private pension coverage. Since social security provides public medical coverage only for very poor or retired people, this is an important effective difference between the primary and secondary labour market. However many female and young part-time workers are covered for private health insurance by family policies subscribed by the main income earner.

Japan's regime is in an intermediary category. Part-time workers do benefit from general social security coverage (including health insurance) as in Europe but there are income ceilings beneath which second family workers do not need to pay social security contributions. Part-time workers often do not benefit from employment protection rules and custom as in the case of regular and life-time jobs. Their basic wages may be below those wages of regular employees. and they will often not receive bonus payments either (see Hobara, 1985).

Table 15: Structure of part-time employment by age and sex in the EC (9) and United States, thousands

	(years)	EC men	(1983) women	total	(years)	US men	(1985) women	total
young	(14-24)	532	1,223	1,755	(16-24)	2,446	2,995	5,441
prime age	(25-49)	568	7,010	7,578	(25-54)	878	5,569	6,447
older	(50+)	935	2,859	3,784	(55+)	1,162	1,715	2,876
Total		2,035	11,092	13,117		4,486	10,279	14,764

### 10. Summary and Conclusions: Options for Policy Reform in Europe

The first option for consideration is the most radical: total deregulation. This is not a purely theoretical hypothesis. It was for a long time the regime of the United States, although the judiciary is through case decisions now increasingly filling the void left by the absence of federal legislation. Economists and business school writers in the United States who recognise the advantages of employment security for employees and many enterprises often draw the conclusion that the optimal degree of employment security can be introduced through collective bargaining or the simple choice of the enterprise. On the other hand, there are arguments favouring an extension of employment security in industry in the United States beyond what the free market has so far delivered. Moreover, the legal regime for coping with disputes over individual dismissals in the United States appears to be in increasing difficulty, in the absence of general legislation providing a framework for case decisions.

The reason for rejecting a de-regulation option for Europe would not, therefore, be only political. As noted above, employment security provisions generate a number of effects on labour costs, employment and productivity, some favourable and some unfavourable. The net impact seems likely to vary considerably between size of firms and types of activity. Therefore the proposition of blanket deregulation would seem ill-adapted. While, the United States' regime appears on close inspection to be less satisfactory than sometimes suggested, Japan has succeeded in reconciling considerable employment security with little unemployment. Politically, total deregulation in Europe would no doubt create very great conflict and instability in industrial relations. Even in the hypothesis of total deregulation by the state, reasons of

economic efficiency would recommend that a large share of total employment would be governed by security of employment contract. The process of wholesale renegotiation of employment contracts in all enterprises in the economy to make explicit what deregulation had rendered unspecified would be an awesome prospect.

A second approach to reform is to consider amending existing legislation where it appears to be unduly onerous, thus retaining the existing legal framework as the basis. A reasoned evolution of the status quo is proposed. In fact the foregoing survey of the existing law in Europe and Japan shows that there are a very large number of eminently negotiable variables filling the space between, on the one hand, the regime of total deregulation and that, on the other hand, of the most constraining possible set of regulations. A struggle over choosing between total deregulation versus total regulation would be not only conflictual but also unnecessary, given the opportunities for fine graduations in the setting of the policy variables. A selection of these variables may be recalled for illustrative purposes: the length of notice for dismissals, the amount of compensation per year of service, the criteria determining fair versus unfair dismissal, the criteria governing temporary and fixed-term contracts, the role of workers' representatives in procedures leading to redundancies, the extent of exemptions from the standard laws for small enterprises, or for young or elderly workers etc.

Four general principles are proposed for reviewing the optimality of employment protection rules:

- the social and economic qualities of secure employment for a large proportion of employees and enterprises should be reflected in the basic design of the law;
- however, the differences of situation between categories of employees and enterprises should be recognised, so as to avoid excessively rigid constraints either for employees who do not need or want it, or for enterprises who need flexibility in the size of their labour force most;
- it should be possible to sanction the shirking worker by dismissal, subject to legal safeguards against abuse;
- the enterprise should retain the prerogative of judging the requisite size of its labour force and for deciding therefore upon the need for collective redundancies. However, this should be subject to respect of minimum requirements for financial compensation

and procedural delays for consultation with workers' representatives and to assure that alternative courses of action to collective redundancies are fully exploited.

As regards policies on individual dismissals the comparison of national regimes suggests the following points. The sharpest issue is whether the employer has in effect the power to dismiss a person for reasons of his misconduct or poor work performance. In general European law distinguishes between "grave misconduct" and "unsatisfactory work performance". Generally "grave misconduct" covers criminal acts such as theft and bodily violence. In these cases summary dismissal is, to the extent of the author's knowledge, provided for in all European countries. The situation of "unsatisfactory work performance" (laziness, incompetence or lack of appropriate skills) is more varied. European practices range from an apparent even-handedness of the law in some countries (the United Kingdom for example) to the practical impossibility of dismissal in others. The latter kind of regime covers a number of different practices, such as the need to prove incompetence to the courts (Portugal), the policy of the courts to override professional criteria with social criteria (Italy), or the extremely onerous or time-consuming procedures that recourse to the courts entails (Belgium, Germany, Sweden). Excessively protective legal procedures have two economic disadvantages. The small enterprise in particular can be discouraged from taking on staff outside the family where the sanction of dismissal is absent. The working atmosphere and productivity of a team of workers can be adversely affected by the presence in their midst of a worker who does not pull his or her weight.

As regards collective redundancies, the requirements of the EC Directive in this domain seem to be quite justifiable in laying down the basis for a consensus model. Minimum prenotification periods are required, as are consultations with workers' representatives and compensation payments as a function of length of service. More controversial, and going beyond the E.C. Directive, are provisions in which either trade unions or governments retain powers of approval or authorisation. Governments have power of approval in the Netherlands, Spain and Portugal, and powers to defer action in Germany. Management can in these cases claim that a basic prerogative is being denied to them. This is countered in some cases with the argument that the labour ministry intervenes with a light hand, or that the political difficulties for a firm in making redundancies may actually be eased by the approval of the government. The essential point would seem to be whether enterprises, in their recruitment

planning, fear the probability of future constraints on their freedom to adjust their labour force when demand is low. For several European countries surveys suggest that this is the case. In some countries the level of minimum compensation payments is also relatively high and perceived to be so by the enterprises.

As regards lay-off and short-time working arrangements, there seem to be some reasons for preferring the European system of short-time working, rather than the United States system of total lay-offs. While the most effective regime doubtless depends upon the technology of individual industries, short-time working has the advantage of greater equity among workers and less discontinuity of work experience. In Italy the lay-off scheme has come to be abused to the considerable cost of the state budget: very high compensation payments go to many people who for long periods of time find supplementary employment.

Temporary work and fixed-term contract regulations allow for derogations, in Europe and Japan, from the dominant regimes of permanent and secure employment contract. In the United States there are simply no such regulations, because the dominant regime places little or no constraints on individual or collective termination of contract. An important question for European and Japanese policy makers is, therefore, how wide and open these derogations should be. Some countries have made the regulatory restriction on temporary work and fixed-term contracts extraordinarily severe. As noted above, for example, Italy and Sweden prohibit private temporary work agencies, whereas most European countries license such agencies in order to guard against abuse of weak members of the labour force. Other countries limit temporary or fixed-term work contracts very narrowly to certain skills or circumstances. On condition that social security and minimum wage laws are respected for such employees, there would be two advantages in opening up opportunities for employment of this type. First, on the labour supply side, many people who are marginal participants in the labour market (youths, elderly people approaching retirement, second workers in families) are not as interested in long-term security of employment as is a middle-aged principal income earner of a family with dependents. Secondly, on the labour demand side, much of potential employment growth appears to lie in small business and service enterprises which have a stronger economic preference for short-term employees, compared with larger and technologically advanced firms which have a greater need for long-term employees.

Similar considerations apply to the supply and demand for part-time work. The case for assuring that these workers also are covered by social security is strong. However, their need to be covered by the employment protection regime for permanent workers is not so strong, especially if there is here, as is to be suspected, a quite sharp trade off between the volume and security of job creation. For many marginal members of the labour force the buoyancy of job offers is a far more plausible source of effective employment security than the long-term nature of employment contracts for a relatively small number of job opportunities.

As regards rules of recruitment favouring disadvantaged workers, there are in most European countries quotas for handicapped workers, whereas there are no significant policy instruments of this type in the United States. In Europe policy techniques range from simple mandatory quotas, to indicative quotas supported by the taxation of under-performing enterprises and subsidies for those employing more than the quota. The latter policy would seem more efficient, given unevenness in the possibility of different firms to absorb handicapped workers and the distortions seen in attempts to evade mandatory quotas (such as keep a firm below a minimum size). Italy is alone in having some other recruitment regulations in which official employment agencies have a role to saying whom enterprises should select. These administrative processes seem quite archaic and due for scrapping.

The policy strategy for employment protection regulations should not be decided in isolation from the specific objectives of economic policy. In the present European context three wider issues may enter into the picture:

- objectives for the labour force participation rate;
- interdependence in the choice of policy strategies for employment protection on the one hand, and for wage rigidity or flexibility on the other;
- judgements about the acceptability of a certain duality in the labour market in the interests of maximising employment and minimising threats to acquired rights.

As regards the labour participation rate, relaxations in employment regulations that led to increased job creation would also be likely to induce an increased supply of labour, for example among the young, elderly and second income earners in the family. The crucial question therefore is whether the European economy needs a rising labour force participation rate, or whether it should alternatively invest in labour supply reducing measures (early retirement

scheme, etc.) to help achieve a better balance in the labour market. Demographic and social security financing considerations strongly point in favour of increasing the labour force participation rate, without which social security taxes will rise further (thus hurting labour demand), or pensions will have to be cut, or both. Of course, in this case, such policies favouring expanded labour supply should also be accompanied by suitably expansionary macroeconomic policies to assure that demand is adequate.

It is often observed that the United States has flexible hiring and firing rules but not so flexible pay levels, that Japan has considerable rigidity in hiring and firing rules but relative flexible pay levels, whereas Europe is relatively rigid on both accounts. The implied policy choice for a Europe wishing to improve its employment situation is between aiming at either greater flexibility in job tenure or in pay levels, or some compromise mix of the two. There are several reasons favouring the compromise approach. As noted above, a policy of total deregulation of employment protection law would seem to be undesirable on economic efficiency as well as political grounds. On the other hand a policy of total reliance on greater pay flexibility would be very difficult to secure for at least two reasons: first, the strength of institutional rigidities lying behind collective bargaining behaviour and, second, the fact that rigid employment protection laws serve to prevent labour market pressures, notably from the unemployed, from bearing upon wage bargainers. Therefore a complementary approach seems preferable, aiming at moderate and mutually supporting reforms in the direction of both employment protection and pay systems.

As regards the dual labour market question, there are issues here of two kinds. Firstly, there is the possibility, already mentioned, of stimulating a faster growth in the future of short-term and part-time employment if certain changes in employment protection law were implemented. Secondly, there is the issue of whether to acknowledge acquired rights in terms of job security laws of existing job-holders, but to change the rules for new employees. There are several arguments that go in the direction of admitting rather than resisting these types of increased labour market duality.

With a much increased labour supply as well as demand, many of the additions to the labour force would be relatively favourably disposed towards short-term and part-time jobs. This prospect sometimes leads to fears being voiced about creating increased "under classes" in

the labour market. However, for Europe this fear would seem not to be very pertinent in a situation in which immigration from developing countries has been stopped (unlike in the United States), and in which the universality of social security coverage would be maintained (also unlike the United States, where health care is not obtained with low level jobs). Relaxations of constraints on short-term work would, for example, be envisaged especially for young and elderly workers.

Some countries (Germany, Spain) have in recent years reformed their employment protection laws in the direction of allowing firms much more liberal recourse to fixed-term contracts for new recruits. This particular policy move has the quality that the situation of the existing labour force on permanent contracts is not changed, whereas many new recruits may have a different status. The rationale favouring such moves is two-fold. By leaving the existing labour force unaffected, this avoids the risk that a general relaxation of the rules at a time of relatively weak business cycle conditions would cause a flood of dismissals. On the other hand the marginal cost of new employment is reduced since there would be no expected severance costs. While such a development would mean a kind of increased duality, its social acceptability should also be rated relatively favourably since it would help break down the differences of interest between insiders (those currently employed in permanent jobs) and outsiders (those currently unemployed) in the labour market. Indeed, this duality among the employed would seem more preferable than the graver social duality separating the employed from the unemployed.

Annex 1Regulations Governing Individual Dismissals

<b>United States</b>	No general law. In absence of contract or collective bargain employer or employee could, in principle, terminate at will without notice or compensation. However, the judiciary increasingly erodes this situation, often inflicting heavy damages on employers in disputed cases.
<b>Japan</b>	30 days notice required. For dismissal for economic reasons see collective redundancies. Discharge as disciplinary punishment possible. For ordinary dismissals courts will nullify if company's action unreasonable or not based on common sense of society.
<b>Germany</b>	Legislation of 1969 and 1972 permits summary dismissal for gross misconduct. Otherwise notice of 2-3 months required, Works Council must be consulted, dismissal must not be "socially unwarranted". Works Council must approve dismissal, if not employer must appeal to Labour Court, pending which employment must continue. Compensation for unfair dismissal 1 month pay per year of service.
<b>France</b>	Legislation permits summary dismissal for gross misconduct. For dismissal for economic reasons employee is entitled to public retraining facilities and minimum financial compensation (as for collective redundancies).
<b>Italy</b>	Industry and trade union agreement of 1965 and legislation of 1966 and 1970 require employer to supply proof of justified reasons; employee may demand meeting with trade union and employer, a hearing before arbitration and appeal to the courts. Compensation for unfair dismissal not less than 5 months pay. Dismissal considered practically impossible except for criminal acts.
<b>United Kingdom</b>	Legislation of 1975 and 1978 protects against unfair dismissal. Employee can appeal to arbitration and tribunal, employer has to show substantive reasons. Notice of 1 week per year of service, compensation 1/2 to 1 1/2 weeks pay per year of service.
<b>Belgium</b>	Legislation of 1966 and 1978 permits summary dismissal for gross misconduct. Otherwise notice of 7 to 56 days for blue-collar workers or 3-15 months for white-collar workers is required (often longer by collective agreement). Appeals to tribunal may lead to compensation for unfair dismissal of at least 6 months pay.
<b>Netherlands</b>	Legislation permits summary dismissal for gross misconduct. Otherwise approval of Labour Office must be obtained, with notice of 1-6 months week per year of service.
<b>Denmark</b>	Notice periods and severance pay is largely left to (legally enforceable) collective agreements.
<b>Sweden</b>	Legislation of 1982 requires notice of 1-6 months, and consultations with trade union if requested. Compensation for unfair dismissal 16-32 months pay.
<b>Finland</b>	Notice periods and severance pay generally set in collective agreements. No legal obligation to pay indemnities other than wages during notice period.

Norway	Legislation of 1977 requires notice of 2 weeks - 6 months unless otherwise agreed. Consultation with shop steward mandatory. Employee may appeal to the court, normally being retained on full pay meanwhile. Compensation for unfair dismissal according to court decision.
Ireland	Tribunal system judges complaints of "unfair dismissal," which if funded leads to reinstatement or up to 2 years wages in compensation. In 1983 200 cases were found in favour of employee, 370 cases against.
Austria	Notice periods of 6 weeks to 5 months. Works Council consent must be obtained. Compensation of 2-3 weeks per year of service. Reinstatement customary in event of unfair dismissal.
Switzerland	Legal minimum notice periods of 1-3 months usually extended by contract or collective agreement, which also determine severance pay.
Spain	Dismissals for economic reasons require agreement of Labour Office, which is not given before 30 days, possibly deferred by a further 30 days. Compensation for unfair dismissal up to 42 months pay.
Greece	Dismissal permitted after written notice and indemnity linked to length of service.
Portugal	Legislation of 1975 prohibits dismissal without "just cause", which covers gross misconduct, but not professional inability. Employee can appeal to the courts, which will require proof of "just cause".

Annex 2Regulations Governing Collective Redundancies

United States	No general law. 15% of collective bargains contained advance notification provisions (in 1980).
Japan	Case law establishes extensive preconditions for legally admissible redundancy of regular workers: objective need to reduce labour force, prior recourse to internal staff transfer, natural wastage, work-sharing, dismissal of temporary workers, call for voluntary retirement. Consultation of work force required. Compensation not required by law, but customarily substantial.
Germany	Legislation of 1969 requires prenotification of Labour Office and Works Council of 30 days. Labour Office may extend by a second month. Notice and compensation as for individual dismissals.
France	According to laws of 1964 and 1979, employer must first consult Works Council (which must prepare its opinion within 14 weeks) and then request authorisation of Labour Office (which may defer its decision up to 30 days). Severance pay for hourly personnel, 20 hours wages per year of service minimum. Law of 1986 abolishes role of Labour Office in authorisation and shortens statutory delays.
Italy	Following notification, trade unions may delay by 25-40 days. Collective dismissals considered practically impossible, unions tend to occupy plant until agreement negotiated.
United Kingdom	Legislation of 1975 requires earliest possible notification of Labour Office and consultation with trade unions, minimum period up to 90 days. Compensation of 1/2 to 1 1/2 weeks pay per year of service, depending upon age, with 35% subsidised by public funds for firms with less than 10 employees.
Belgium	Legislation of 1975 requires 30 days, prenotification to Labour Office, which may extend this by 60 days. Works Council must be consulted. Compensation as for individual dismissals.
Netherlands	Legislation of 1976 requires 30 days prenotification of Labour Office. Works Council and trade union have to be consulted. Labour Office must authorise. Compensation according to age and service.
Denmark	Works Council must be informed, and Labour Office given 30 days prenotification. Compensation determined by contracts.
Sweden	Notice of 2-6 months required, with consultation of trade unions, Labour Office and local authorities. Compensation by collective agreement.
Finland	Prior discussions with work force required. No legal obligations to pay compensation.
Norway	Labour Office and shop steward at earliest possible stage. No legal obligations to pay compensation.
Ireland	30 days notice, after employees have been consulted and Labour Office informed. Compensation as for individual dismissals.

- Austria** Discussions with trade unions and Works Council required at least 30 days in advance. Compensation as for individual dismissals.
- Switzerland** No general legislation. Prior notification recommended in a general collective agreement of 1975. Compensation depends mainly on collective agreement.
- Spain** As for individual dismissals, 30 days minimum prenotification; Labour Office authorisation required. Compensation 20 days pay per year of service.
- Greece** Authorisation of Labour Office required for firms with more than 20 employees, and where redundancies exceed 2% of the work force per month. Indemnities legally required.
- Portugal** Prenotification of 60-90 days given to Works Council, trade unions and Labour Office. Authorisation of Labour Office required. Compensation of 1-2 weeks pay per year of service.

### Annex 3

#### Resolution of Disputes Over Individual Dismissals in the United Kingdom - By Arbitration and Tribunal

The British system of resolving disputes over unfair dismissal is of interest in that it appears to have qualities of expedition and even-handedness that are often absent in other countries. The law provides that "every employee shall have the right not to be unfairly dismissed by his employer" (Industrial Relations Act of 1971 and Employment Protection Act of 1978).

In the period 1976 to 1982 about 40,000 cases of contested individual dismissal arose per year on average. The majority of cases are resolved in arbitration, where it often becomes evident how the case should be decided. However about 10,000 cases are heard in the industrial tribunal. About 30% of such cases tend to see the dismissed employee's complaint upheld, with the larger percentage found in favour of the employer.

The law provides that certain grounds for dismissal are automatically illegal (race, sex, marital status). Certain other grounds are automatically unfair (pregnancy, membership of a trade union, trade union activities). Capability, conduct, redundancy and "other substantial reasons" are potentially fair grounds for dismissal, depending upon reasonableness.

The industrial tribunal consists of three persons with a lawyer (in the chair), and representatives of employers and employees. Judgements allow considerable room for managerial prerogative. Thus the high court of appeal has ruled "when a man is dismissed for incapacity or incompetence it is sufficient that the employer honestly believes on reasonable grounds that the man is incapable or incompetent. It is not necessary to prove that he is in fact incapable or incompetent."

In the event of the tribunal judging that dismissal was unfair, basic compensation is awarded of 1/2 to 1 1/2 week's pay per year of service with possible entitlement to a larger amount. Reinstatement is possible but rare (3-5% of cases).

Surveys have been made of the system and of the views of claimants and defendants. Cases are generally heard within three months, and disposed of in a day or less. The system is relatively informal, and claimants often present their own cases. The majority of participants find that the time taken to reach judgements is about right, and have a favourable view of the tribunal system.

As regards the impact of the system on recruitment, brochures of the Department of Employment draw attention to the relatively low success rate of complaints against unfair dismissal, thus seeking to dispel undue fears of small employers over the difficulty of dismissal.

Annex 4Texts from some Japanese Judicial Decision on Dismissals

The following two cases, one concerning an individual dismissal, the other collective redundancies, illustrate the use and content of court decisions in defining the rules of dismissal in Japan. They are extracts from the court decisions, as reproduced by Sugeno (1985).

1. Abuse of Right of Dismissal

Supreme Court Judgement, January 31, 1977, Second Petty Bench (Shioda v. Kochi Broadcasting Co.) 268 Rodo Hanrei 17.

Facts: The Plaintiff had been employed by Defendant company as an announcer. He was committed the following negligence which fall into the reason of discipline prescribed in the Work of Rule of the Company.

1. Plaintiff was working overnight from 6:00 p.m. of February 22nd of 1967 until 10:00 a.m. of the next morning together with a reporter in charge of new manuscript. He overslept until around 6:20 a.m. of 23rd and could not broadcast entirely the regular news program which was due to be done for 10 minutes from 6:00 a.m. (the first failure).

2. He also worked overnight together with another reporter from 7th to 8th of March of the same year and again missed a news program for 5 minutes from 6:00 a.m. in the morning of 8th (the second failure).

3. He failed to report the second failure to his superior and submitted a report with some camouflage when he was requested to report by the director of his section around March 14th and 15th. The Company did not take a disciplinary punishment (discharge) but simply dismissed him taking his future fate in consideration. Plaintiff brought the case to the court asking to confirm his employment status holding that the dismissal is too severe and abuse of right of dismissal. In both of the first and second instances the Courts admitted the Plaintiff's request and declared the dismissed null and void. The Supreme Court sustained the original judgement.

Excerpt of the Court's Opinion

Plaintiff's above described failures in this particular case fall under the reason of (ordinary) dismissal prescribed in the Article 15, No. 3 of the Work Rule of the Company too. However, even when there is a reason of ordinary dismissal the employer is not always permitted to dismiss the employee. The dismissal could be null and void as abuse of the right of dismissal when the the dismissal is extremely unreasonable and not to be admitted to be appropriate based on the common sense of the society depending on the actual situations of the individual case. In this particular case, two failures he had committed were in their nature something to damage the social credit of the Company. The fact that he had overslept and caused the same kind of failure twice in two weeks showed his lack of responsibility as an announcer. Furthermore, he had not admitted his failure in the second case not straight-forward. All these points he is certainly not blameless. However, judging from the facts confirmed by the original instances his failures were not caused by his malice or on purpose but by his negligence, namely oversleeping. It is rather too harsh to blame only Plaintiff since in both cases of his failure the reporters were supposed to wake him up but they also overslept and failed to wake up and to give him the manuscript of the news program. Plaintiff had apologized immediately after his first failure and in the second case he tried to start work as soon as he woke up. In both cases the vacant period of broadcasting was not so long. The Company was not taking a perfect arrangement to secure the early morning new program. His submission of a camouflaged report was partly a result of his misunderstanding of whether the door of the first floor was closed or not and partly a result of his awkwardness because of his repeated mistakes in a short period. Judging from all these points he is not to be strongly blamed. He has committed no failure in

announcement work until this time. His performance has been not particularly bad in the past. The reporter in the case of the second failure was punished only by warning. No announcer was dismissed because of the failure in broadcasting in the past. Plaintiff has finally apologized for the second failure too. Judging from these circumstances to dismiss him is rather too severe and tends to lack in reasonableness. Thus it could possibly be regarded as inappropriate in the common sense of the society. Therefore the judgement of the original instance holding the dismissal of this case as abuse of the right of dismissal and null and void is proper.

## 2. Dismissal Due to Closing Down of Division

Tokyo High Court Judgment, October 29, 1979 (Toyo Sanso K. K. v. Koji Shimazaki et al.)

### 30 Rominshu 1002

**Facts:** The Appellant, having its principal office in Tokyo and business offices and factories in eight locations throughout Japan, is engaged in the business of manufacturing and selling various high pressure gases such as oxygen, acetylene and liquefied petroleum gas. (As of 1970, the amount of capital was 1,520,000,000 Yen, and the number of employees as 532.) The Appellant decided to close down its entire acetylene division and on July 24, 1970 informed all 47 employees of the division, including another 12 other appellees, of its intention to dismiss them. This action is a request for a preliminary injunction for a preserving position filed by the Appellees, 13 employees among the 47, asserting that this dismissal is an abuse of the dismissal power.

Tokyo District Court (April 19, 1976, 255 Rohan 58) granted the Appellees' petition. That is, the first trial held that "in order for the dismissal of the Appellant's employees in a certain division which has been closed down to be considered valid when as, in the instant case, the Appellant asserts unavoidable business necessity; the closing down of the division should be reasonable from a management point of view, as should be the dismissal of the employees, and moreover the dismissal procedures should be generally acceptable to society." The court found that the first condition had been satisfied for the following reasons. In general, even when the management for unavoidable reasons has to close down a specific business division it goes without saying that the employees in the division should hopefully be minimal. Therefore, when the Appellant closed down the acetylene division, it should have tried to avoid dismissal of the employees in the division as much as possible by taking steps such as transferring the employees to the Appellant's other business divisions, or by calling for voluntary retirement among the employees in the division or in the whole company. If the Appellant dismissed all the employees in the division without taking such steps in spite of the fact that it was able to do so, then it can be said that the dismissal was not unavoidable from a business management point of view.

### Excerpts From the High Court's Opinion

The judgement of the Tokyo District Court shall be reversed, and the petition of the Appellees shall be dismissed.

In general, an enterprise can freely decide to close down a specific business division, since it is a decision with respect to management policy within its exclusive discretion. This does not directly mean, however, that the enterprise, as an employer, can freely dismiss the employees in the division when it decides to close down the division. In order for the employer's decision dismissing the employees in the division to be justified as being based upon "unavoidable business necessity," the following requirements shall be met and considered sufficient except in unusual circumstances. First, the closing down of the business division must be found to be based upon unavoidable necessity from the viewpoint of reasonable management of the enterprise. Second, the dismissal for the reason of the closing down of a business division should not be arbitrary on the employer's part. Such a dismissal can be held not arbitrary only if there is no room for transferring the employees to identical or similar jobs in the other business divisions in the same or other business locations not far from the original place of business, or if there is no way to avoid a surplus of employees in the whole enterprise even after the execution of the

above-mentioned transfer. Third, the selection of the actual retirees should be based on objective and reasonable criteria.

Annex 5Conclusions of a Study by (Manes and Rosenbloom of the Harvard Law School) on the United States Legal System for Handling Disputed Individual Dismissals (Excerpts)

"The Current system for handling claims of unfair discharge, if one may call it a system at all, is not working. The courts continue to create more problems than they resolve. Society, as well as employers and employees, has been ill served by the law's response to the problem of unfair discharge. The conclusion seems unavoidable that legislation is required to balance the interests of all concerned.

"Our survey of the current case law leaves little room to doubt that the judicial system does not adequately promote the interests of employers or employees. By its very nature the litigation process is slow, costly, and formal. Some commentators claim that the courts lack the necessary labor expertise and perspective to properly address unfair discharge problems. Clearly courts have been anything but uniform in their decisions, as judges have attempted to combat perceived unfairness by formulating rules which often are both over and under inclusive. Ultimately, these rules are ill tailored to protect either the employees' or employers' interest. Further, handicapped by the limited remedies a judge can adopt, and the erratic manner in which juries allot compensatory and punitive damages, the courts are destabilizing the employment relationship.

"Case by case adjudication has proven to be a poor way of regulating the employment relationship. Already courts have begun to express the fear that their duty to develop a common law of wrongful discharge threatens to render the court a bargaining agent for every employee not protected by statute or collective bargaining agreement.

"The courts themselves recognize the need for legislative action. Although sympathetic to the unfairness that may accompany the dismissal of an at-will employee, many courts nonetheless feel that the legislature is the appropriate agency for effecting a change in policy regarding the employer-employee relationship. In Murphy v. American Home Products Corp., New York's highest court refused to recognize the tort of wrongful discharge. The court reasoned:

Those jurisdictions that have modified the traditional at-will rule appear to have been motivated by conclusions that the freedom of contract underpinnings of the rule have become outdated, that individual employees in the modern work force do not have the bargaining power to negotiate security...and that the rule yields harsh results for those employees who do not enjoy the benefits of express contractual limitations on the power of dismissal. Whether these conclusions are supportable...are issues better left to resolution at the hands of the legislature.

...If the rule of nonliability for termination of at-will employment is to be tempered if should be accomplished through a principaled statutory scheme, adopted after opportunity for public ventilation, rather than in consequence of judicial resolution of the partisan arguments of individual adversarial litigant...

"Similarly, the Connecticut Supreme Court recently noted:

What categories of employment should be given [protection] and what criteria should determine whether there exists good cause for a discharge are questions which the General Assembly may deal with more comprehensively than the courts.

"In view of the erratic and inconsistent judicial development of the law of 'unfair discharge', we believe a better approach to the problem may be found in state legislation. Moreover, there

is more that recommends a legislative approach than simply the failure of courts to provide a comprehensive and effective solution to the wrongful discharge problem. The policy issues that arise are intensely political, and resolution of these issues will not be found merely by referring to the 'brooding omnipresence' of the common law, but rather by informed public discussion. The history of labor regulation in this country has of necessity been a history of balances and trade-offs. It is this 'trading-off' of employer and employee interests that legislatures are uniquely qualified to perform."

# Selected Labor Market Reforms

*Aline Coudouel and Pierella Paci*

Overall, in recent years, the policy advice of bilateral and multilateral donors to policymakers in developing countries has been centered on reducing the degree of government intervention in the functioning of the labor market and on increasing the liberalization of labor market institutions. Underpinning this advice is the traditional neo-classical assumption that the *laissez-faire* approach ensures the highest social welfare by promoting labor market efficiency and job creation.

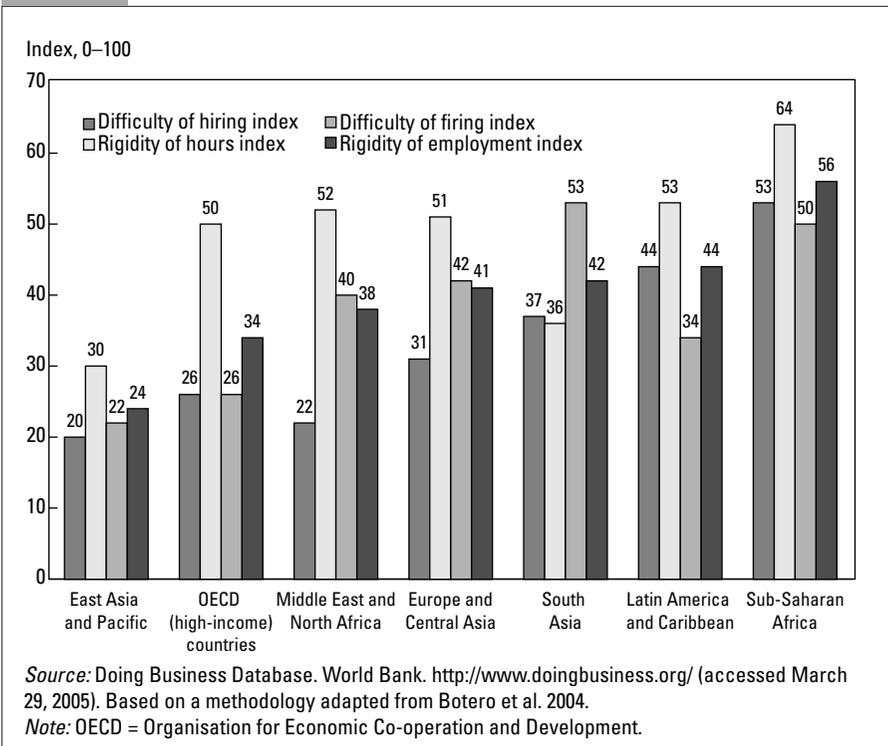

However, this view has long been challenged by those who see in the many market failures in the labor markets of developing countries the need for a more active role for labor market policies. A number of non-competitive theoretical frameworks question the efficiency of unregulated markets, provide a rationale for different types of labor market interventions, and, in combination with the *Theorem of Second Best*,<sup>1</sup> challenge the view that liberalization always leads to increased efficiency. In addition, the strongest criticism of the *laissez-faire* approach is based on considerations of equity and on poverty reduction objectives on the grounds that the outcomes of unregulated, competitive labor markets are not necessarily consistent with the social justice objective. The different definitions of social justice or *equity* preclude any simple answer to this question (Barr 1993). However, the claim becomes much easier to assess when the focus is on poverty and on income distribution. The argument here is that labor market interventions reduce inequality in labor incomes by (1) maintaining earnings at the lower end of the income distribution above the level at which they would have been in an unregulated market, and (2) reducing the vulnerability of earnings.

Employment is widely perceived to be among the most important channels through which the poor can move out of poverty. This is mainly for two reasons. First, labor is the most abundant asset of the poor, and, second, what distinguishes the poor from the non-poor is labor incomes: labor force status is repeatedly found to be a critical determinant of household welfare in developing countries. Thus, among other studies, the recently released “Pro-Poor Growth in the 1990s: Lessons and Insights from 14 Countries” (World Bank 2005) highlights employment as a crucial link between growth and poverty reduction; it identifies labor market regulations and segmentation and the links between the investment climate and employment as priority areas for pro-poor growth strategies. Yet, access to jobs is not sufficient; the existence of so many *working poor* underlines the importance of the availability of jobs that offer some degree of security and pay *decent* wages.

From this arises the essential role of labor market policies designed to improve job security and guarantee a decent wage for the most vulnerable workers. However, this potential role would clearly be significantly reduced if the security of decent labor incomes for some was achieved at the cost of reduced employment opportunities and more inadequate working conditions for others. This raises important challenges for policymakers, such as: (1) how to design a package of labor market policies that reconcile the right of workers to secure and decent wages—which is essential for reducing poverty and labor market vulnerability—with the overall objective of widening employment opportunities; (2) how to implement any necessary reform of the existing package of interventions; (3) how to quantify the potential distributional impact of any such reform; and (4) how to minimize the welfare costs to those people who would lose out from these changes.

These are important issues for development as, contrary to expectations, the developing world generally tends to have relatively rigid labor laws governing the relationship between employers and employees. This is evident in Figure 3.1, which presents four indexes of labor market rigidity, ranging from 0 to 100, from least to most rigid. The indexes are as follows:

- the difficulty of hiring index, which is based on the legality of part-time and fixed-term contracts and their applicability
- the rigidity of hours index, which is based on the rules that govern the hours of work (maximum, treatment of night-shift work, overtime, and so on), the policy toward work leaves, and the minimum wage

**FIGURE 3.1 Selected Indexes of Labor Market Rigidities across Regions**

- the difficulty of firing index, which is based on the grounds allowed for firing, the firing procedures in place, the firing notification requirements, the size of severance payments, and whether the right to job security is enshrined in the country's constitution
- the rigidity of employment index, which is a synthesis of the three indexes above

Figure 3.1 shows that, with the exception of the East Asia and the Pacific Region, formal labor markets in all regions exhibit labor market rigidity that is greater than the average for the countries of the Organisation for Economic Co-operation and Development (OECD). The greater rigidity is particularly evident in firing restrictions and employment regulation. The rigidities are especially substantial in Sub-Saharan Africa, where all the indexes are in excess of 50, and hiring and firing are twice as difficult than they are in the OECD countries. At the other end of the

spectrum are the East Asian countries, which have, on average, much less stringent laws.

However, it may be misleading to derive conclusions about the overall degree of the rigidities of the labor market from the findings shown in Figure 3.1. This is because the coverage of these laws and their level of implementation vary considerably from country to country partly as a reflection of the size and structure of the informal sector. Indeed, for most, labor market policies only apply to a subset of the workforce, namely, those people in the formal sector. As shown in Table 3.1, the size of this subset varies considerably across regions and countries, but it represents over 40 percent of gross domestic product in Africa and Latin America and 35 percent in the transition countries of Europe and Central Asia. In addition, in countries with weak implementation capacity, large pockets of unprotected employment persist even in the formal sector.

This suggests that labor market legislation directly affects employment conditions only for a relatively small percentage of the workforce in the developing world. Nevertheless, it is likely to affect the incomes and the vulnerability to poverty of a much larger part of the population than the small percentage covered by the policy. Indeed, evidence has emerged that conditions prevailing in the formal sector have indirect effects on the informal sector by, for example, raising the average wage in both sectors. More importantly, the degree of intervention prevailing in the formal sector may represent a barrier to job creation in general and to the employment of new workers in particular. It may also affect the size and structure of the informal sector: informality may be more widespread, and the gap between the formal and informal sectors may be larger in economies with more highly regulated labor markets.

**TABLE 3.1. Average Size of the Informal Economy in Terms of Value Added, by Region, 2000**

<i>Region</i>	<i>Value added (% gross domestic product)</i>	<i>Countries covered (number)</i>
Africa (including North Africa)	41.0	23
Latin America and the Caribbean	41.0	18
Middle East and Asia	29.0	26
Central and Eastern Europe and Central Asia	35.0	23
Western European OECD	18.0	16
North America and Pacific OECD	13.5	4

*Source:* Schneider and Klinglmaier 2004.

Thus, labor market policies and policy reforms are an important determinant of income distribution and poverty incidence even in countries where the relative importance of the covered sector in the overall labor market is small. This is because of the indirect effect of the policies and the reforms on the rest of the economy. Indeed, when the focus is on improving overall social welfare and reducing poverty, labor market interventions may act as a double-edged sword by protecting the income levels and security of those covered by the policies, the *insiders*, while increasing the vulnerability of the rest of the population, the *outsiders*, who may face increasing barriers to employment and have access only to jobs in the uncovered sector of a typically *dual* labor market.<sup>2</sup> For this reason, any reform of the prevailing labor market is unlikely to be Pareto neutral. It will leave some members of society worse off, while improving the living standards of others and will therefore have an important distributional impact. Who the winners and losers will be will depend on a number of factors, ranging from the type and direction of the reforms—that is, more intervention versus increased liberalization—to the characteristics of the labor and output markets.

In deciding on the implementation of these policies and reforms, policymakers should thus be fully aware of the potential direct and indirect impacts on the distribution of income at both the individual and the household levels so that the full significance of the policies and reforms in terms of efficiency, equality, and poverty reduction can be adequately evaluated.

The objective of this chapter is to provide policymakers with the tools they need to conduct such an evaluation. The chapter first describes a variety of labor market policies, focusing on three of these policies. It then describes possible reforms of these policies and the rationale behind the reforms. The subsequent section illustrates the channels by which the reforms may impact income distribution and poverty. The following section identifies the stakeholders involved in each of the reforms analyzed. Finally, the tools of analysis and the main impacts of the reforms as identified in the empirical literature are outlined.

The chapter is not intended as a full-scale analysis of the pros and cons of particular labor market policies and reforms, but more simply as a guide to the comprehensive evaluation of potential distributional impacts. Thus, the attention is on the possible effects on income inequality and the incidence of poverty rather than on the efficiency of the system or the existence of a trade-off between efficiency and equity considerations.<sup>3</sup>

## LABOR MARKET POLICIES

The types of labor market policies implemented in countries are many and varied. In the interest of maintaining a tight focus, the analysis in this chapter is limited to the potential distributional impacts of reforms in three areas of labor market policy that are of particular relevance to developing countries, namely, the minimum wage, employment protection legislation, and unemployment benefits.

The chapter neglects other types of labor market policies and reforms<sup>4</sup> and the potential interactions of these reforms with the conditions prevailing in other areas of the labor market.<sup>5</sup> In addition, the analysis takes a partial-equilibrium approach and does not deal with the issue of possible interactions between, on the one hand, capital and product market institutions and reforms and, on the other, the reforms of labor market interventions; nor does it address the potential impact of labor market reforms on the competitiveness of a country vis-à-vis its neighbors. These are important limitations because the status and the sequencing of reforms in product and labor markets are clearly interrelated, and the changes in labor costs brought about by reforms may have important second-round effects on labor market outcomes and income distribution, as shown by the examples in Box 3.1. However, the decision to focus on only three types of labor market policies and to analyze these three in isolation from other reforms both within and outside the labor market is dictated by the need to keep the task within manageable dimensions.

### BOX 3.1 Labor Market Reforms Do Not Happen in a Vacuum

Recent empirical literature on economic liberalization has unveiled a number of interactions among labor market reforms, their impact, and the conditions prevailing in other markets. For example:

- Evidence from South Asia points to the importance of industrial policies in determining the impact of labor market reforms.
- Trade liberalization appears to have led to the expansion of the informal sector in Colombia until a major labor market reform also increased the flexibility of the labor market (Goldberg and Pavcnik 2003).
- Soaring minimum wages and labor costs in Indonesia are believed to have eroded the country's competitiveness (Agrawal 1995).
- Analyses of European countries show that the effects of shocks depends on the nature of institutions. Shocks have a larger and more persistent effect in countries with poor labor market institutions, and a similar shock has differentiated effects on unemployment when labor market institutions differ (Blanchard and Wolfers 1999).

## The minimum wage

Minimum wage legislation sets a lower bound to the wages paid to individual workers. The conceptual definition is very simple, but the scale, eligibility, and policy design differ considerably from country to country. The majority of countries opt for a single national minimum rate set on an hourly, daily, weekly, or monthly basis. Beyond the single national wage, a reduced or subminimum rate is sometimes applied for some groups of workers, notably, youth, the unskilled, or the long-term unemployed; for most workers, subminimum rates sometimes exist de facto, because special employment programs allow employers to pay lower wages for young workers. In other countries, minimum wage premiums are sometimes used that are related to worker characteristics. For example, the minimum wage may rise according to worker experience, worker qualifications, or worker family status.

In addition, different minima may be set for different regions, occupations, or industries. This is particularly common in Latin America. For example, in Argentina, there are dozens of minimum wages set for agricultural workers, while one minimum wage is set for all other economic activities (World Bank 2006), and, in Mexico, wages are set separately for three regions and 88 occupations (Gindling and Terrell 2004a). Countries also vary in the process they adopt to set the minimum wage. The government sets it unilaterally in some countries. In others, it is the result of negotiations between representatives of workers and firms. In a number of countries, it is indexed to price inflation. The available information on selective features of minimum wage policies across countries is summarized in Table 3A.1 in the annex to this chapter.

Such diverse approaches make international comparisons of minimum wages difficult. Nevertheless, cross-country comparisons can be made by measuring the value of the minimum wage relative to some measure of average wage (the *Kaitz index*). Maloney and Mendez (2003) provide estimates for the Kaitz index for most Latin American countries. They find a large variance across countries. Argentina, Bolivia, Brazil, Chile, Mexico, and Uruguay represent the lower bound (with a Kaitz index around 20–25 percent), while El Salvador, Honduras, Paraguay, and Venezuela are among the countries with the largest values (with estimates around 50–60 percent). The evidence for African countries is less readily available. Jones (1998) finds that, in Ghana, the Kaitz index for manufacturing workers fell from 50 percent in the early 1970s to around 20 percent in the early 1990s.

## Employment protection legislation

Employment protection legislation refers to the set of norms and procedures to be followed when hiring or dismissing workers. The legislation typically obliges employers to give workers a monetary compensation in case of early termination of permanent contracts and imposes procedures to be followed in case of individual or collective layoffs.<sup>6</sup> It also imposes constraints on the type and length of the available contracts, for example by limiting the use of temporary contracts.

Typically, the legislation governs *severance payments* and *advance notice*. A *severance payment* is a monetary transfer to a worker in case of firm-initiated layoff. The payment may include compensation for unjustified dismissal, seniority premiums, and compensation for wages forgone during any legal process if the worker brings an action against the firm,<sup>7</sup> and so on. An *advance notice* is a specific period of time allowed to the worker before a layoff can be implemented. Firms typically either provide notice and keep the workers during the notice period or provide a compensation equivalent to the wages that would have been earned during the notice period. When workers continue on the job during the notice period, their level of effort is likely to be reduced, which translates into an extra cost for the employer. In addition to mandatory payments, some firms and sectors also have collective agreements that specify other requirements. These components of the legislation can be conceived of as *monetary transfers* similar in nature to wages.

Another aspect of the legislation is the *administrative procedures* that must be followed. In most countries, the employer is required to discuss layoff decisions with the representatives of the workers. In some countries, dismissals must be approved by authorities (for example, India), and, in most countries, the legislation distinguishes between *individual* and *collective dismissals*. Within individual dismissals, a distinction is usually made between economic dismissals and disciplinary dismissals (often not covered by the legislation). The procedures for collective dismissals apply to large-scale restructuring and typically impose tighter administrative burdens in the form of prolonged consultations with worker representatives. The legislation may also govern the distribution of legal costs if workers contest dismissals by initiating court proceedings. These components of the legislation can be conceived of as “*taxes*” since they correspond to payments to third parties.

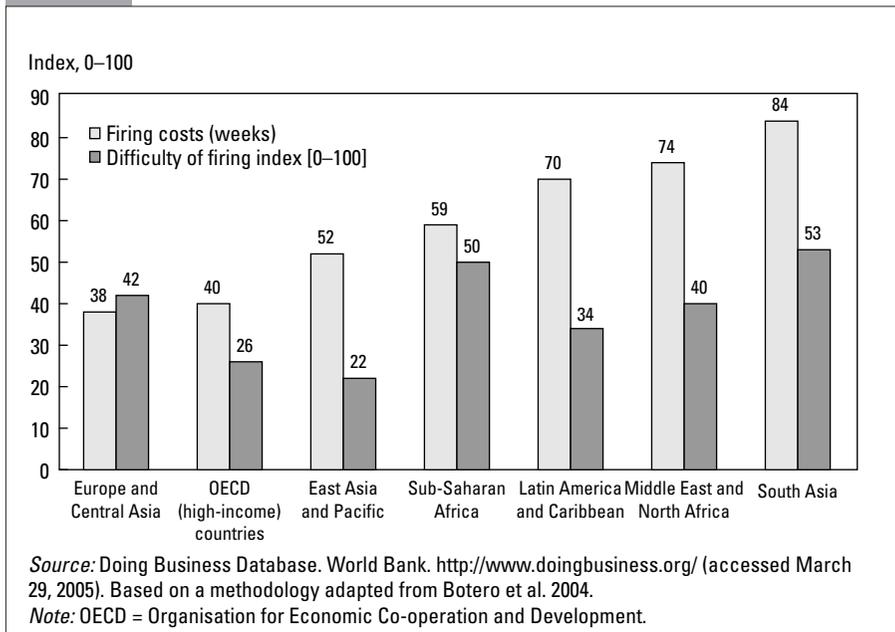

The multifaceted character of the legislation throughout the world makes international comparisons of the nature and comprehensiveness of the legislation difficult. However, several synthetic measures of the rigidity of the legislation exist. International comparisons of two of these

indicators are illustrated in Figure 3.2. The figure shows the *difficulty of firing index*, which ranges from 0 (least rigid) to 100 (most rigid), and the *firing costs* expressed in weeks. Figure 3.2 indicates that firing existing workers is far more difficult in the developing world than in OECD countries. Firing is two times more difficult in South Asia and Sub-Saharan Africa than in the OECD. Firing costs are also much higher in developing countries than in OECD countries. In South Asia, they are over twice those in the high-income countries of the OECD.<sup>8</sup> A more complete breakdown of the values of synthetic indicators of the strictness of employment protection legislation by country and region are provided in Table A3.2 in the annex to this chapter.

### Unemployment benefits

The objective of unemployment benefits is to provide income to individuals during spells of unemployment. Typically, the systems function as insurance schemes, whereby the amount and duration of the benefit are based on the worker's employment history, past contributions to the system, and most recent wage (unemployment insurance). Some schemes

**FIGURE 3.2** An International Comparison of Selected Indicators of Employment Protection Legislation

also include a component that is independent of the worker's profile and (usually) provides flat benefits to individuals with long unemployment spells or who are below a certain income level (unemployment assistance). In most developed economies, unemployment benefits are combined with other transfers designed to supplement income for individuals who are out of work, such as early retirement schemes, invalidity pensions, and social assistance benefits. In addition, alternative ways of supporting the income levels of the unemployed while increasing their reemployment opportunities have recently been tried by a number of countries. These policies, commonly referred to as active labor market policies, vary substantially in their characteristics and in the degree of their success both as safety nets and as a means of reemployment. Vodopivec and Raju (2002) offer an extensive review of alternative systems of income support for the unemployed and an evaluation of the relative merits.

Several key features characterize an unemployment benefit system. Among these are the level of payments, the duration of the payments, and the eligibility requirements. To deal with the size of the benefit and the length of time during which the benefit is provided, the OECD tabulates a "summary measure of benefit generosity," defined as the average replacement rate during the first two years of unemployment for an "average production worker" having sufficiently long seniority to be offered the benefits up to their maximum duration. Another useful indicator is the coverage rate, that is, the fraction of the unemployed population receiving benefits. This measure depends on the duration of the benefits and the characteristics of unemployment (in particular, the share in unemployment represented by those individuals who typically do not benefit from the system because of a lack of work experience).

### **The potential interaction between different policies**

The three policies highlighted in this chapter interact in interesting ways. This is particularly true of the unemployment benefit and employment protection legislation because the effects of the benefit are likely to differ depending on how flexible the legislation is, and, to a degree, the legislation and the benefit can substitute one for the other. However, in order to maintain a tight focus, this chapter does not address the topic.

## **TYPES OF REFORMS AND THE RATIONALE OF REFORM**

The rationale for labor market intervention has traditionally been based on the argument that the market for labor is a very special type of mar-

ket because of its nature and the fact that it deals in people rather than goods. This makes issues of equity particularly important and also makes the occurrence of market failures more likely and worrisome. In the view of many, this implies that an unregulated labor market would lead to outcomes that are inequitable and inefficient and that some form of intervention is required to increase the efficiency of the labor market and enhance the equity of its outcomes. However, many other people believe that the acceptance of this argument has caused labor markets to become excessively regulated in numerous wealthy and less wealthy countries and that this has led to outcomes that are neither efficient nor equitable. Based on these two competing views, calls for reform have focused on the implementation or strengthening of interventionist policies or on their weakening. For the most part, this has led only to marginal changes designed to alter the coverage or the generosity of systems.

### Reforms of the minimum wage

In addition to the setting or elimination of a minimum wage, reforms in the area of the minimum wage are typically of two types: those that either increase or decrease the average value of the wage threshold and those designed to introduce subminimal wage floors for particular groups of workers (such as the unskilled, youth, or the long-term unemployed) or locations or regions (areas of high unemployment or poor areas). The main rationale for a generalized increase in the minimum wage is the need to ensure a *living wage* to all workers and concerns about excessive wage inequalities. In such a context, the introduction or increase of a minimum wage acts as an instrument for redistributing income within a formal labor market characterized by large numbers of “working poor.”<sup>9</sup>

On the other hand, a reduction in the average minimum wage or in the minimum wage of specific types of workers is advocated when the existing level of the relevant minimum wage appears to act as a barrier to employment either across the board or among workers characterized by particularly low productivity, typically youth, the unskilled, or the long-term unemployed. The introduction of regional variations in the minimum wage may also be advocated in a context of differences in the cost of living across regions or systematic differences in labor demand or skill levels across parts of a country.

Thus, these contrasting proposals reflect two different views of the impact of the minimum wage and of minimum wage reforms. One view stresses the *redistribution dimension* of the minimum wage, while the other view stresses the *quantity crowding out* dimension. These two different

views also reflect the key transmission mechanisms of the minimum wage, as described in more detail below.

### Reforms of employment protection legislation

The range of possible reforms in employment protection legislation is large, but the reforms are mostly linked to concerns about long-term unemployment and large pockets of unemployment among specific groups, typically the young and women. Any legislative initiative that induces a change in the regulations on individual or collective dismissals can be considered a reform in employment protection legislation. Furthermore, since the rigidity and enforcement of the legislation depend also on the way the judicial system applies and interprets the legislation, changes in the functioning and organization of the judicial system are also an important factor in legislative reforms.

One may distinguish between radical and marginal reforms. *Radical reforms* typically refer to changes in the regulations that apply to all jobs (for example, changes in the level of severance payments, the length of the required advance notice, the definition of fair dismissal, court procedures and the burden of proof, collective dismissal procedures, and so on). *Marginal reforms* refer to changes that apply only to newly created jobs. These include changes in the regulations on temporary or atypical contracts (for instance, interim contracts) and so on.

As shown in Table 3.2, by far the most popular reforms in employment protection legislation in Europe since 1985 have been marginal ones. Each country has, on average, undertaken one reform every other year, and the reforms have reduced or increased protection in equal shares.<sup>10</sup> The numerous reforms have led to an expansion in contractual types and a growth in the number of both fixed-term and unstable jobs, as well as permanent and still heavily protected positions. This has increased the dualism in European labor markets, making them more segmented not only with respect to insiders and outsiders, but also with respect to various sorts of outsiders.

**TABLE 3.2. Employment Protection Legislation Reforms in Europe since 1985**

	<i>Increasing protection</i>	<i>Decreasing protection</i>	<i>Total</i>
Structural reforms	7	4	11
Marginal reforms	59	53	112
Total	66	57	123

## Reforms in unemployment benefits

The main reforms in unemployment benefits consist of changes in the duration of benefits, in entitlements, and in replacement rates. The reforms are often designed to realize policies to encourage labor market activity and labor force participation or to increase the incentives for unemployed individuals to take up jobs. In addition, a number of countries have also recently been experimenting with alternative ways to support the income levels of the unemployed, while increasing their reemployment opportunities. These policies, commonly referred to as active labor market policies, vary substantially in their features and in the degree of their success as safety nets and as a means to boost reemployment.

An analysis of reforms in unemployment benefits in the European Union since 1987 shows that reforms in basic benefit systems are numerous, with an average of two reforms in each country every three years. Most of these reforms have aimed at augmenting benefits, but have only entailed marginal changes (that is, phasing in new beneficiaries rather than changes in existing entitlements) or have increased the rewards for labor market participation by altering the incentive structure. Finally, reforms have typically taken place during phases of economic growth and have often involved simple changes in administrative rules, for example, requiring more frequent visits to an employment office before one is eligible to receive benefits or rewriting the definition of “suitable job offer.” This reflects the fact that the implementation of administrative reforms during economic growth is often less controversial than changes in benefit levels.

To avoid the opposition of people already covered by the system, more radical reforms to benefit systems are typically implemented little by little via marginal adjustments in benefits and a gradual narrowing of entitlements. Benefit reforms therefore usually “grandfather” existing entitlements by exempting those individuals who are receiving benefits at the time of the reform and allowing for the new rules to be phased in. An important exception is represented by the case of the former planned economies of Central and Eastern Europe, where fiscal constraints and the need to set right the perverse incentive structure that prevailed before the transition led to dramatic reforms, which, in some instances, severely reduced benefits and halved the maximum duration of benefits (Boeri 2000).

There are three main reasons for carrying out reforms in unemployment benefits. The first relates to the observed positive correlation between the duration of a benefit and the *duration of unemployment*. Exits from unemployment are found to respond strongly to the benefit-entitlement period (the exit rate increases as workers near the end of their

entitlements). A second reason relates to the effects of benefits on *unemployment levels*. More generous benefit systems tend to be associated with higher unemployment rates because of longer unemployment and because of a dampening effect on entries into the workforce. A third reason for benefit reforms is the *fiscal cost* of the benefit system that, in conjunction with other nonemployment benefits, may account for a significant proportion of social spending.

### **The argument for implementation and strengthening of labor market interventions**

From an efficiency perspective, the arguments for significant intervention in the labor market focus on the existence of different causes of *market failure*. First, the efficient working of a market under *laissez-faire* conditions requires full information flows. However, the substantial degree of heterogeneity among workers and jobs makes information flows highly complex and the costs of acquiring and updating information extremely high, leading to the use of infrequently updated stereotypes that distort decisionmaking and may put some groups systematically at a disadvantage, that is, either by being discriminated against in employment decisions or by being paid less than their marginal value product. Second, the presence of externalities may distort the relationship between individual utility-maximizing objectives and the overall objective of maximizing social welfare. A third potential source of market failure may arise when product market monopolies, trade unions, or a labor market monopsony cause the relationship among productivity, real wages, and employment to be distorted, leading to inefficiency in resource allocations.<sup>11</sup> Finally, the failure of markets for goods, services, and resources to perform efficiently may distort the operation of demand and supply.

Box 3.2 provides examples of the different categories of labor market failures discussed above. It is important to note that these are not mutually exclusive. On the contrary, they may interact to generate widespread market failures. This is particularly evident in the case of unemployment insurance.

An additional argument for labor market intervention derives from the fact that contracts for employment are more likely to be incomplete than are contracts prevailing in goods and output markets because of the “idiosyncratic” character of labor as a factor of production. Indeed, contracts involving the exchange of labor have dimensions other than duration and terms of employment that cannot be easily quantified or communicated, such as attentiveness, effort, and creativeness. Since these

**BOX 3.2 Examples of Types of Market Failures in the Market for Labor**

The following are examples of the four prevailing types of failures of the market for labor in developing countries.

1. *Asymmetric information.* In many situations, information is available asymmetrically in the labor market. This is a particular problem in markets with less effective reputation effects, that is, markets characterized by small firms, mobile workers, and informal contractual arrangements.
  - Firms may find that it is expensive to discover the true characteristics of applicants, and job-seekers may find that it is difficult to discover the true characteristics of job offers.
    - Off-the-job search is inefficient.
  - Employees may be unable to obtain full information on job-security arrangements in their current jobs.
    - They may make inefficient decisions about training and job-seeking.
  - Firms may conceal their difficult financial situations in order to prevent new job-seeking and departures by their most valuable workers.
2. *Externalities.* There are many examples of externalities in this area.
  - In deciding whether or not to close a branch, firms are unlikely to internalize the costs to local workers or to the government in the form of lost tax revenues and increased benefit payments.
  - In deciding whether or not to accept jobs, unemployed job-seekers are unlikely to take into account the costs of their refusal for firms or for the government.
  - If firms or workers are prepared to internalize these costs, free-riders who have failed to do so may nevertheless share in the resulting benefits.
    - Private decisionmaking in the unregulated labor market is inefficient because it does not internalize these costs.
3. *Monopoly power* may result from a number of factors both in the labor market and the product market and affect both demand and supply.
  - The existence of technologies idiosyncratic to a particular firm means that skills obtained through on-the-job training cannot be transferred to other employers. This makes labor turnover costly.
    - Virtually all employees and firms possess some degree of monopoly power.
    - Labor mobility is restricted; the labor market is not competitive, and wages may not clear.
  - Trade unions or monopolistic behavior may lead to similar distortions in the wage and employment equilibrium.
4. *Absence of markets for goods and services* may distort the operation of both the demand side and the supply side of the labor market.
  - The investment decisions of individuals may be distorted by the inability of workers to realize the value of their human capital in the same way they sell their financial assets.
    - There will be underinvestment in education and training.
  - The inability to obtain full insurance against redundancy because of the risk of moral hazard may distort interfirm mobility.

dimensions are not specified in the contract, they cannot be enforced, and the agency problem results. Thus, contracts need to be designed to increase the incentives for workers to behave in a manner that is consistent with the interest of employers, that is, supply-acceptable levels of effort and so on, or, more technically, “no shirking.” These incentive mechanisms may involve piece-rate systems of pay or internal promotion that may distort the operation of market forces, leading to the development of internal labor markets and requiring intervention.

Finally, Keynes argued that, in the context of a more aggregate approach toward labor contracts, competitive labor markets are prone to coordination problems, resulting in aggregate market failures and persistent aggregate unemployment. These difficulties derive from the fact that contracts are negotiated at regular, but potentially long intervals and in terms of money wages. Meanwhile, worker demands are motivated in terms of real wages, and the offers of firms are motivated by labor costs. This means that any adjustments will be achieved through employment rather than wages. More recently, the “new growth theory” has expressed concerns about the ability of unregulated labor markets to produce optimal growth performance because of the failure of private employers to internalize the full development benefits of the existence of a trained and educated labor force.

However, the argument most often used to justify labor market interventions is the one based on *equity*. Many question the capacity of an unregulated labor market to produce an outcome that is socially acceptable given the fact that the trade in individual labor is involved. The various definitions of social justice or equity preclude any simple response (Barr 1993). Nonetheless, calls for equity become much easier to address when the focus is on poverty reduction since employment at a “decent” wage is widely perceived as the most important channel through which the poor can move out of poverty. It is also somewhat easier to evaluate the impact of policies on earning distribution and on earnings variability. This is because labor market policies, for the most part, are designed to reduce inequalities in labor incomes by maintaining earnings at the lower end of the income distribution above the level at which they would have been in an unregulated market, as well as to minimize income vulnerability in the light of possible dismissal, unemployment, and so on.

### **The argument for less labor market intervention**

In recent years, the policy advice of bilateral and multilateral donors to policymakers in developing countries has been centered on reducing

government intervention in the labor market and increasing the liberalization of labor market institutions. Underpinning this advice is the conviction that, despite the clear potential for market failures and the active role labor market policies can play in promoting a more equitable distribution of incomes and in reducing poverty, labor markets across the world tend to be overregulated. This overintervention may result in significant efficiency costs that lead to a trade-off between efficiency and equity. Furthermore, some have argued that, in the name of equity and fairness, excessive intervention may ultimately hurt those very groups it is designed to protect: the vulnerable and the poor. This can happen in a number of ways.

At the simplest level, overintervention may result in excessive government expenditure, and the imposition of taxes to finance this expenditure will reduce efficiency. Taxes will distort key relative prices, such as those between work and leisure on the supply side and those between labor and capital on the demand side. These distortions cause labor market behavior to deviate from that consistent with economic efficiency by, for example, discouraging formal employment, reducing employment potential, or generating growth in the uncovered, untaxed informal sector at the expense of the formal one. Similarly, interventions in the minimum wage or through employment protection legislation, by prohibiting employment under certain conditions, reduce the freedom of choice of workers and employers. When excessive, they may prevent the signing of mutually beneficial labor contracts, which would have important implications for the overall level and distribution of welfare. In addition, enforcement of these policies requires resources that could be used more directly for wealth creation.

## **STAKEHOLDERS AND THE POLITICAL ECONOMY OF REFORM**

It is clear that any type of reform is likely to have important distributional effects because of the differential impact on the welfare of various groups in society; some groups may benefit, while others will likely lose out. However, the losers and the winners will be specifically determined by the type of policy and the nature of the reform.

### **The minimum wage**

One important difference between reforms of the minimum wage and reforms of other labor market institutions is that the former mostly affect the bottom of the income distribution in contrast to, for example, changes

in the structure of unemployment benefits, which directly affect all workers. Indeed, the main winners from a rise in the minimum wage are those workers who thereby enjoy a wage increase. Meanwhile, the losers are those people who lose their formal jobs because of the related reduction in employment. Typically, both groups are *unskilled workers in the formal sector*. The opposite is true for a reduction in the minimum wage. Finally, the expectation is that the introduction of differentiated minima for groups or regions facing particularly high risks of unemployment will benefit workers from these groups or regions. In the case of the introduction of subminimal wages for selected groups, the policy may disadvantage other workers at the same level of productivity because employers would tend to replace more expensive workers with those at the subminimal wage.

In addition, *workers slightly above the minimum wage* are also likely to be (or to be afraid of being) affected by reforms because they risk being replaced by workers at the minimum wage. Indeed, they would benefit from a rise in the minimum wage if this reform results in the elimination of the least skilled (the employment effect) since it would increase their marginal value and hence their wages. On the other hand, they would suffer from a reduction in the minimum wage, since it might bring less-skilled workers into the market, and they might lose their jobs. Hence, semiskilled workers might support an increase in the minimum wage, although they do not benefit directly from such an increase.

*Workers in the informal sector* are also likely to be indirectly affected because the minimum wage may come to represent a “fair wage” and hence a binding constraint on employers in the informal sector who need to attract labor and minimize labor turnover. Some *employers* are likely to lose from reforms that increase the minimum wage, but the extent of the loss will partly also depend on their ability to elude the increase via an increase in shadow activity or other subtle methods to lower the effective hourly wage without violating the statutory minimum (for example, by extending working hours or reducing training schemes).

Reforms that decrease or increase the minimum wage are relatively simple to implement and have no direct *fiscal implications*. The administration of the minimum wage is also rather simple, and this limits the need for a sizable enforcement agency.

## Employment protection legislation

*Insider workers* hired under permanent contract in the covered sector are those for whom the bulk of employment protection legislation applies

directly. They are likely to suffer from radical reforms that soften the legislation since this might increase the chance they will lose their jobs. Thus, radical reductions in the scope of the legislation are generally difficult to implement because successful reforms typically need the approval of the median voter, who is likely to be an insider worker protected by the legislation. This might explain part of the resilience of job-security provisions and the difficulty of implementing radical reform once the institutions are in place. In such a context, marginal reforms seem to be the only politically viable option since they do not affect the median voter. A toughening of the legislation reduces the probability of exiting employment for those currently employed, but also increases the difficulty of finding a new job if one is lost. This produces a sense of insecurity among protected workers, who tend to exert pressure to maintain a high level of protection. Since protected workers tend to have greater political power than outsiders, they will typically oppose any diminution in the legislation.

The *outsiders*, on the other hand, include workers in the informal, uncovered sectors, the unemployed, and workers with fixed-term contracts. For them, a relaxing of the legislation usually has a positive impact in that it increases the hiring rate and, hence, the chance of these people to enter employment as insiders. However, these groups are unlikely to have sufficient political power to bring about the required reforms, and poorer, marginalized workers (youth, women, the unemployed, the discouraged) will tend to become more marginalized.

Finally, *capital owners and shareholders* are likely to benefit from a relaxing of the legislation, both marginal and structural, because strict legislation is akin to a tax on capital since it forces capital to be allocated to low-productivity jobs.

## Unemployment benefits

More generous unemployment benefit systems tend to redistribute from less exposed workers to more exposed workers and from the employed to the unemployed. However, the extent to which different groups will gain or lose depends on the strength of the various effects.

Under strong wage effects (when adjustments in the labor market occur through wage compression rather than through employment reduction), *insider workers* are more likely to suffer from reductions in benefits. Consequently, employed workers oppose reforms and may benefit from strong support from unions. Conversely, currently *unemployed individuals* may be more prone to accept benefit cuts because they may realize potential increases in job-finding rates. The progressivity of

unemployment benefits is also important. *Skilled workers* may support reductions in strongly progressive systems (or oppose the extension of progressive systems) since they do not benefit so much from these systems. For instance, they might oppose the introduction of a flat rate. Finally, when reforms have a strong active labor market policy content, both employed and unemployed individuals might be winners. Indeed, these policies increase the welfare of outsiders (by increasing expected job-finding rates), while reducing payroll taxes earmarked for unemployment benefits. They may also increase the wages of insiders. Overall, surveys in Europe eliciting the preferences of individuals for benefits (Boeri, Börsch-Supan, and Tabellini 2001) find that the demand for benefits is stronger among unemployed individuals than it is among all employees.

*Unions* often oppose reforms that reduce the generosity of benefit systems. This is partly because unions typically represent a relatively unskilled segment of the workforce and because unions are sometimes directly involved in the management of benefit systems.

### **The political economy of reform**

Since both intervention and the lack of it have the potential of leading to inefficient and inequitable outcomes, the desirability of labor market intervention depends crucially on the nature and characteristics of the policy. Some policies and intervention designs lead to improvements in efficiency and equity, while others result in a trade-off between the two dimensions, and still others represent a definite worsening in both dimensions. Consequently, it is not possible to evaluate the need for a reform and the potential impact of a reform on poverty and growth without a careful evaluation of the impact on labor market efficiency and income distribution.

Moreover, even in cases in which such an evaluation dictates a particular reform, the actual implementation of the change is never simple for reasons of political economy. This is because the reform is unlikely to be “Pareto neutral” due to its differential impact on the welfare of various groups in society; some groups will benefit, and others are likely to lose out. The magnitude and direction of these benefits and losses will depend crucially on the type of policy under revision and on the details of the reform.

One concern derives from the consideration that a government’s decisions on these and other matters may reflect more its overwhelming desire to be reelected rather than the objective of maximizing social welfare. This has two important negative implications. The first might be

called short-“termism,” whereby policies aiming at long-term social welfare gains that take more than one election cycle to become fully realized are less likely to be implemented than those aiming at a more immediate impact. An example of policies that risk being neglected would be a policy designed to match school education, skill training, and labor market employment.

On the other hand, governments will tend to favor policies that, while suboptimal in terms of welfare impact, may produce tangible gains, but generate costs that are so widely diffused that they are not perceived as costs or are so perceived only by groups or individuals who have little voice and limited political power. Examples of this type of intervention are provided by minimum wage legislation and employment protection legislation.

An example of a highly popular policy with insubstantial or negative welfare impact is the practice of subsidizing the purchase of shares in newly privatized companies. Meanwhile, depending on the prevailing political economy conditions, interventions that have great potential impact, such as improving information flows in the labor market, may be neglected by governments since the benefits are widely dispersed and unlikely to have an important influence on the popularity of the government.

A final rationale for the introduction of and support for interventions that are inefficient is provided by the theory of regulation. The analysis of Peltzman (1976) emphasizes that: (1) regulation confers benefits on certain market participants by providing subsidies or restricting competition; (2) in a static model, by doing this, regulation redistributes wealth toward particular groups; and (3) these groups try to retain or strengthen the regulation by providing political or financial support to sympathetic politicians. Excessively high levels of minimum wage or overly strict employment protection legislation provide good examples of policies that can be introduced and retained despite their potentially negative impact on social welfare.

## **IMPACT PATHWAYS**

Reforms of the labor market have important potential impacts on income distribution and poverty via their impacts on the level and distribution of wages and employment. On the whole, more binding and stricter policies result in higher wages for covered workers at the expense of employment in general and covered employment in particular. Thus, the overall effect of a reform depends on its combined effect on the demand and the

supply of labor in the covered sector and in other sectors of the economy. This effect differs across policies and labor market conditions. In any examination of key transmission mechanisms, it is crucial explicitly to consider the *dual* dimension of the economy and distinguish between the formal or covered sector, where the policies apply, and the informal or uncovered sector, where they either do not apply or are not enforced.<sup>12</sup>

### **The minimum wage**

The overall effects of changes in the minimum wage on income distribution and poverty depend on the characteristics of the labor market.

#### ***Effects on the level and the distribution of wages in the covered sector***

Minimum wage legislation involves establishing a floor for wages so that the equilibrium wage cannot drop below this floor. The expectation is that the introduction of minimum wage legislation or an increase in the minimum wage will, *ceteris paribus*, result in a compression in wage distribution and a reduction in wage inequality in the formal sector since it boosts the wages of the lowest-paid workers above the unregulated market equilibrium. Conversely, a reform designed to reduce the minimum wage across the board or among selected groups of workers is expected to increase earnings inequality.

However, evidence suggests that the effect of changes in the minimum wage are not limited only to workers at the lower end of the wage distribution. Indeed, a rise in the minimum wage may lead to a shift in the wage distribution and an increase in average wages, and part of this increase may be enjoyed by workers with earnings higher than the minimum wage. If this is the case, any reduction in wage inequality may be considerably less than anticipated.

#### ***Effects on the level of employment in the covered sector***

In a perfectly competitive labor market, the imposition of a minimum wage above the equilibrium wage—or an increase in the value of the minimum wage—would generally reduce employment through a reduction in labor demand along an upward-sloping labor supply. Workers whose marginal value product is below the minimum wage are forced out of employment; classical unemployment arises and can only be reabsorbed by lowering the minimum wage. If, in addition, the increase in the minimum wage results in an overall increase in wages, the reform will lead to a generalized reduction in employment across the earnings distribution. The extent of this reduction and the overall change in labor incomes

received by workers in the covered sector depend on the elasticity of labor demand (at constant output). Across the world, this typically varies between  $-0.15$  and  $-0.75$ , with an average of  $-0.45$  (Hamermesh 1993).

On the other hand, if a labor market or any of its segments are dominated by a single employer, the monopsonist, then the impact of an increase in the minimum wage may be very different. The reason for this conclusion is that the monopsonist can affect the equilibrium wage by deciding on the volume of hiring. If labor supply grows with wages, the monopsonist will have an incentive to restrict hiring in order to benefit from low wages. In this context, a rise in the minimum wage is perfectly consistent with a rise in employment. Thus, for a sufficiently low level of starting wage, an increase in the minimum wage could be accompanied by an increase in employment. However, above some specific threshold, the traditional negative relationship sets in. This result is very important. However, three caveats are in order:

- Pure monopsony situations are very uncommon; they may occur in specific geographic areas where labor mobility is low and the number of firms is small.
- An increase in the minimum wage acts positively on employment only when the initial level of wages is low (below the competitive wage); this is not common in most real-life markets.
- The impact on employment of a rise in the minimum wage depends on the elasticity of labor supply; labor supply has little elasticity on average.

Over the last 10 years, a number of papers have studied various imperfect models in which an upward-sloping supply curve at the firm level may arise, implying that the basic monopsony model may become relevant. When imperfect information is pervasive, workers may have an interest in refusing job offers when the wage is too low, since they may get better offers later on. A firm must then choose a wage level that will allow it to attract a sufficient number of workers to meet its needs (Burdett and Mortensen 1998; Masters 1999). This mechanism ensures a monotonic relationship between the wage and the size of firms. Other scholars have proposed variants of the monopsony model grounded in the theory of “efficiency wages.” Manning (2004) summarizes and reviews this research in detail.

The introduction of a subminimal wage among categories of workers characterized by particularly low average productivity (youth) or a high variation in productivity levels (women) has an impact on these

workers that is equivalent to that of a generalized reduction in the minimum wage, that is, it will increase employment among them unless the monopsonist model applies. However, the increase in employment among these workers may be achieved at the expense of a reduction in employment among other workers, and the overall effect on aggregate employment is uncertain.

It appears that no systematic evaluation of the impact of reductions in the minimum wage exists. However, experimental evidence suggests that the effects of changes in opposing directions in the minimum wage are not symmetrical and that the positive effect of a reduction in the minimum wage on employment may be much smaller than the negative effect of an increase of equal proportion in the minimum wage. This is because the existence of the minimum wage results in a permanent increase in reservation wages that does not fully adjust downward when the level of the minimum wage is reduced (Falk, Fehr, and Zehnder 2005).

### ***The impact on wages and employment in the uncovered sector***

In most developing countries, there is a substantial informal sector, and, in large pockets of the formal sector, minimum wage legislation is not applied. This does not mean that these sectors are unaffected by minimum wage reforms since there are important spillover effects between the two sectors. The standard theoretical argument is that, following an increase in the minimum wage, sector wages that are not covered will fall because redundant workers will move into employment in the uncovered sector, and employment in this sector will rise (Gramlich 1976; Mincer 1976; Welch 1976).<sup>13</sup> However, if an increase in the minimum wage in the formal sector leads firms in the informal sector to raise their average wage to keep attracting good workers or because of “fair remuneration considerations,” an increase in the minimum wage can lead to an increase in informal sector wages (the lighthouse effect) or a drop in employment.

### ***The effect on participation, job-seeking, and unemployment***

In the context of a labor market that is supply constrained, the expected impact of the minimum wage may be somewhat different given the existence of endogenous labor market participation and endogenous search effort on the part of the unemployed. One can think of the decision to participate in the labor market as the solution to the trade-off between the value of being an unemployed job-seeker and the value of being engaged full time in home production. In this situation, the increase in the potential benefits of employment generated by the increase in the minimum wage may lead to an increase in labor force participation and

a shift in labor supply that increases employment among the low paid. In addition, if the new minimum wage exceeds the reservation wage, the intensity of the job search by the unemployed and their exit rate from unemployment may rise. Thus, the supply-side effects of the introduction of a new, higher minimum wage may combine to increase employment and reduce unemployment.

### ***The effect of minimum wage reforms on income distribution and poverty***

In evaluating the potential impact of minimum wage reforms on income distribution, it is important to distinguish between earnings distribution and income distribution. The former is defined at the level of the individual and by focusing only on employed workers. The latter is usually defined at the level of households and is calculated according to the total labor income of all household members, plus income from other sources.

An increase in the minimum wage can have both a positive and a negative effect on inequality in household incomes. First, a rise in incomes at the lower end of the income range among the formally employed typically reduces inequality in individual earnings. However, it might also result in less employment among the low-paid workers for whom the minimum wage is binding or in the transfer of some of these workers to the uncovered, less-well-paid informal sector. This could increase inequality in labor incomes both at the individual level and at the household level, especially if workers on the minimum wage live in households with a high proportion of low-skilled, potentially low-paid individuals. The overall direct effect on income inequality depends on labor market conditions, demographics, and household composition.

These effects are compounded by the indirect changes in the sector not covered. If labor is mobile across sectors, then the standard covered-uncovered adjustment mechanisms operate, and an increase in the minimum wage leads to an increase in earnings inequality. Yet, the impact is reduced if the lighthouse effect comes into play, since a higher minimum wage leads to an increase in wages in both the covered market and the uncovered market. In this case, the overall impact on the distribution of household income will depend on the employment dynamics between the covered sector and the uncovered sector, as well as the impact of the reform on the two segments of the labor market.

Reforms of the minimum wage are also expected to have a typically ambiguous impact on the *poverty rate*.<sup>14</sup> An increase in the minimum wage, for example, will typically raise the earnings of low-paid workers who maintain their jobs, and, *ceteris paribus*, this will bring the poverty rate down if these individuals are the lone earners within their households

and if all low-paid earners within households maintain their employment at the prereform level. However, the increase is also likely to reduce employment in the covered sector, and this will result in lower labor income at the household level if any wage earners lose their jobs because of the policy or are forced to transfer to the lower-paying, uncovered sector. This may increase the vulnerability to poverty of households that are close to the poverty line (Brown 1999). However, evidence in developed countries suggests that a large proportion of earners on the minimum wage are second or third earners in households that are well above the poverty line. This substantially reduces the potential impact of minimum wage reforms on the incidence of poverty.

### **Employment protection legislation**

There are four transmission mechanisms through which reforms in employment protection legislation can affect the distribution of incomes and the incidence of poverty.

#### ***Impact of reforms on hiring, firing, and employment levels***

Hiring and, especially, firing are the key standard mechanisms of any reform in employment protection legislation because such legislation tends to increase the cost to firms of initiating a worker separation. Thus, the most direct effect of legislative reform is a change in the rate of firings since the reform affects the tendency of firms to hoard labor—to hold onto marginal jobs—and delay the timing of labor adjustments. However, legislative reform also has an obvious indirect effect on hiring because firms, at the hiring stage, will attempt to anticipate future costly adjustments because of adverse shocks. Strict legislation will therefore reduce the incentive for firms to hire additional workers. The combination of direct and indirect effects suggests that strict legislation will reduce turnover (hiring and firing), while any reform that reduces the stringency of the legislation will lead to an increase in turnover among firms. The effects on the stock of employment are more ambiguous. In equilibrium, hiring and firing among firms offset each other. In this case, the existence of legislation has no clear effect on the average employment level. The key transmission mechanism of employment protection legislation does not imply a reduction in average employment, but rather an effect on the flows of employment.<sup>15</sup>

The transmission mechanism described above can be easily applied to the case of radical reforms, but, when reforms are marginal, the situation is more complicated. This is illustrated by a reform that increases the

availability of fixed-term contracts, a typical marginal reform in OECD countries during the 1990s.<sup>16</sup> The availability of temporary contracts will certainly raise the incentive for firms to hire new workers on a temporary basis. In addition, it will increase the incentive for firms to wait until the expiration of temporary contracts before implementing reductions in personnel. This suggests that a marginal reform in the labor market can lead to the formation of a dual labor market, wherein a stock of protected workers hired under a complete legislative regime of employment protection exists alongside a fringe of workers hired under temporary contracts, and that this dual labor market acts as a buffer against labor market shocks (Blanchard and Landier 2002).

The workings of the key transmission mechanism depend crucially on the behavior of wages and on the use of taxes versus transfers. The baseline transmission mechanism functions smoothly if wages do not adjust in response to changes in employment protection legislation and if a reform relates to a tax component of the legislation. The situation becomes more complicated if wages can adjust, especially in the case of legislation involving transfers.

### ***Wage-bargaining***

Another important transmission mechanism involves the effect of employment protection legislation on the *threat point* of wage-bargaining for insider workers. The existence of such legislation reduces a firm's threat point in the bargaining over the wages of insiders because insiders are protected by the legislation against dismissal in case a wage agreement is not reached. As a result, the existence of the legislation leads to higher wages for insider workers.

The key issue is what happens to the wages of outsiders. Most wage-bargaining models predict the emergence of a two-tier regime, whereby the wages of outsiders are reduced because of the legislation. In other words, workers on temporary contracts partly prepay, in the form of lower wages, the future cost of employment protection legislation. The size of the prepayment will depend on whether the legislation provides for a firing tax or a severance payment.

In the case of severance payments, the prepayment is full, so that the expected cumulative wage bill obtained by hiring an outsider is constant. This is the well-known neutrality result of the existence of severance payments and wage flexibility, originally identified by Lazear (1990). It is an important benchmark result, since it suggests that, when employment protection legislation takes the form of a transfer and wages are sufficiently flexible, the legislation is neutral. In the case of firing taxes, the

prepayment is never full, so that the predictions obtained by the standard mechanism apply. To sum up this transmission mechanism: employment protection legislation induces a reduction in the wages of outsiders and an increase in the wages of insiders. In addition, when the legislation provides for a transfer, the effect of wage-bargaining is so important that the legislation is neutralized. The neutrality disappears, however, as soon as wages become rigid or if the legislation provides for a tax rather than a transfer.<sup>17</sup>

### ***The effort of workers and labor productivity***

Another transmission mechanism revolves around the impact of employment protection legislation on worker productivity. Since such legislation increases job security, it automatically reduces the incentive of workers to make any extra effort and, thus, in turn, reduces labor productivity. While it is true that an increase in job security can certainly lead to an increase in the propensity of workers to shirk, one needs to bear in mind the difference between economic dismissal and disciplinary dismissal; legislative provisions typically govern only economic dismissals, that is, dismissals that are not caused by a shortcoming of the workers (Ichino and Riphahn 2005). If a clear distinction exists between economic and disciplinary dismissals, the potential for an increase in shirking is substantially reduced. In addition, many have argued that the greater job tenure that derives from employment protection legislation may in fact foster an increase in productivity via the higher incidence of job-specific training and greater company loyalty among workers.

### ***Capital-labor substitution and capital allocation***

Employment protection legislation may also have an impact on the prevailing technology. This mechanism was originally discussed by Caballero and Hammour (1998), and it is best understood from the perspective of a sort of putty-clay technology.<sup>18</sup> In the short run, capital is largely fixed and installed, and capital-labor substitution is low. In the long run, however, firms have a much more flexible technological menu at their disposal and can select different capital-labor ratios. This suggests that more encompassing employment protection legislation may have different effects in the short and long run. In the short run, an increase in legislative coverage may result in a tax on existing capital in ways that cause a greater share of the surplus to be captured by labor. The situation is different in the long run. Since employment protection legislation acts partly as a tax on labor, firms have an incentive to invest in labor-saving technologies, leading to an increase in the capital-labor ratio.

Finally, the passage of stricter legislation tends to reduce the reallocation of capital from ailing sectors to expanding sectors. In a sense, this is in the nature of a sclerotic market; it suggests that, in a country with strict legislation, capital is not allocated efficiently. This may have an obvious impact on the average productivity of the economy and may also affect the growth process.

## **Unemployment benefits**

Reforms of the system of unemployment benefits can impact labor market outcomes through various channels.

### ***Impact on unemployment duration and incentives for job-seeking***

Generous, long-term benefit entitlements may provide an incentive for longer spells of unemployment; cross-country evidence demonstrates the existence of this positive association (Boeri, Layard, and Nickell 2001). Thus, a reduction in unemployment benefits is advocated as a way of reducing the duration of spells of unemployment. However, some studies suggest that causality might work the other way: in cases of high long-term unemployment, governments might be pressed to increase the duration of benefits. For instance, changes in the duration of unemployment benefits in some parts of the United States tend to follow upon increases in the duration of unemployment (Card and Levine 2000). This means that the negative effects of benefits on the duration of unemployment may be overstated.

Thus, most benefit systems are designed to discourage recipients from using the system for the maximum duration. For instance, unemployment insurance benefits typically decrease in value over time, and there may be limits on the maximum duration of unemployment assistance benefits or conditions may be imposed in terms of the time or effort spent job-seeking. New policies also provide incentives to increase search efforts by imposing restrictions and conditions on the receipt of unemployment benefits. Finally, assistance in job-seeking is often provided to encourage more active searches. On the other hand, eligibility for unemployment assistance that is based on means-testing at the household level can create strong incentives for other members of the household to leave employment or limit their searches (because their incomes may increase the average household income above the eligibility income threshold).

Reforms reducing the generosity of unemployment benefits (or raising the rewards of labor market participation) provide incentives for the unemployed to increase the intensity of their job searches. Furthermore,

evidence supports the positive effect on employment and on earnings of the provision of assistance in job hunting. Evidence also points to the cost savings arising from the increased flows of people from unemployment to employment generated by the imposition of job-seeking requirements. Finally, penalties on individuals refusing to take up suitable job offers seem to be rather effective in a few selected countries (the Netherlands for example).

### ***Impact on the level and type of employment***

The implementation of an increase in wage subsidies through variable contribution rates among employers for different types of workers may also affect employment and wages, depending on the elasticity of labor demand and supply.<sup>19</sup> A reduction by 21 percent in employer contributions in Belgium for the wages of unskilled workers is expected to increase employment among low-skilled workers by almost 7 percent. Estimates for France and the Netherlands point to similar increases.<sup>20</sup>

Linking benefits to past contributions reduces the incentive to evade payroll contributions and provides an incentive for workers to stay in the formal sector. Since these workers would likely require a higher wage in the informal sector, this also provides an incentive to firms to remain active in the formal sector to avoid paying higher wages.

## **TOOLS OF ANALYSIS AND THE FINDINGS**

Natural experiment is the best empirical methodology for assessing the distributional effects of labor market reforms. This methodology consists of exploiting exogenous changes in the economic environment of certain agents to compare their reactions to those of otherwise similar agents who have not undergone the changes. The influential work of Card and Krueger (1994) on the effect of the minimum wage represents a key illustration of this methodology. However, the opportunity for carrying out studies based on this technique is rarely at hand, and, for the most part, researchers have to find other ways of assessing the impact of labor market reforms.

Computable general equilibrium models can also be useful, but they have to depend on an underlying structure of the labor market in a way that is consistent with the complex effects of the regulation in question. There are two key features that should be kept in mind, particularly if one is dealing with a complex dual labor market in a developing country. First, the analyst should pay special attention during the modeling of both the formal-covered sector and the informal-uncovered sector of the

economy. Second, a model based on a simple two-sector conception of perfect competition is hardly appropriate for assessing the effects of reforms that may have considerably different impacts under different labor market conditions, say, the impact of a reform of the minimum wage in a context of monopsonistic price setting. The literature does not yet seem to provide a good example of complex labor markets that could be used as reference points.

For the most part, the empirical literature focuses on

- evaluating the impact on one particular link in the chain of reactions described above (that is, employment or the wage level), without much consideration of the transmission channels of the impact (that is, the full distributional impact)
- the impact of the implementation of a particular policy rather than the potential effects of reforms in the current system

The review that has been undertaken of methodologies and findings for this chapter covers the existing evidence and treats the implementation or removal of a policy as a type of reform that causes a labor market to become more regulated or less regulated. The findings on each of the transmission channels and on the overall impact on income distribution and poverty are summarized below.

## **Minimum wage**

Over the last 10 years, an extensive amount of research on the employment effect of the minimum wage has emerged, mainly in response to the results of the empirical studies carried out by Card and Krueger (1995). Furthermore, the growing availability of microdata for developing countries has permitted a deepening understanding of the minimum wage in dual markets. Most of the empirical literature analyzes total employment from the perspective of the effects of the introduction of or increase in the minimum wage. Some also focuses on the impact of changes in the subminimal wage on the employment of youth. On the basis of the available evidence, it is not clear that an increase in the minimum wage leads, on average, to substantial job losses. However, the increase may contribute to a shift from formal to informal employment.<sup>21</sup>

### ***Effects on the level of employment***

Card and Krueger (1994, 1995) studied the impact of increases in the minimum wage in New Jersey in 1992 and in California in 1988, taking

Pennsylvania, a state where the minimum wage did not change, as a control. Using a difference-in-difference estimator, they found that, after the minimum wage was raised from \$4.25 to \$5.05 in New Jersey, the level of employment in fast-food establishments rose more quickly in New Jersey than it did in Pennsylvania. They concluded that an increase in the minimum wage may lead to a rise in employment if the wage is sufficiently low at the outset, as it was in New Jersey. (In the literature on development, no evidence derived from natural experiments has been discovered on changes in the minimum wage.)

The research by Card and Krueger generated a vivid debate along two dimensions. The first dimension was the interpretation of the results, for example, whether consumers of fast food can be considered representative of the population as a whole, since it may well be that persons earning minimum wages are typical consumers of fast food. The second dimension of the debate revolved around the fact that the original Card and Krueger study was based on data gathered through telephone interviews and not on administrative data. However, despite the arguments and counterarguments exchanged between Neumark and Wascher (2000) and Card and Krueger (1994), the results of the earlier study seem to have been confirmed.

In the absence of access to the natural experiment methodology, the large majority of empirical studies adopt a methodology that consists of highlighting the aggregate correlation between variations in employment and the minimum wage, while controlling for the other factors that might affect employment. These studies make use of the evolution over time of the minimum wage, as well as differences in the level of the minimum wage across industries and geographic regions. The estimates vary from country to country. Large negative effects are found in Colombia (Bell 1997), Ghana (Jones 1998), Morocco (Agenor and El Aynaoui 2003), and Puerto Rico (Castillo-Freeman and Freeman 1992), while the impact appears to be insignificant in Indonesia and Mexico (Bell 1997; Rama 1996). Carneiro (2004) also finds evidence of a significant reduction in formal sector employment and a shift toward employment in the low-paying informal sector. It is clear that, in this type of study, too many variables are often left out of the analysis, and the coefficients should not be interpreted as robust evidence, but simply as important country-specific correlations.

*Data at the level of firms* are becoming available in developing countries and are often used to estimate the impact of the minimum wage on labor demand. Studies typically use these data on the formal manufacturing sector and regress employment at the level of firms on a set of con-

trols (such as the prices for other factors and value added, if available), a minimum wage dummy, and employment lags to allow for dynamic adjustment.<sup>22</sup> The estimates of the impact vary across countries. The effect of the minimum wage appears large and negative in Colombia (Bell 1997; Maloney and Mendez 2003), but small or negligible in Costa Rica and Mexico. In Indonesia, the sharp increase in the minimum wage registered between 1990 and 1996 appears to have reduced employment in small domestic firms, but not in larger ones, foreign or domestic. Meanwhile, the impact on total employment was found to be positive in Brazil, but was the result of a composition effect between hours and jobs; the total number of hours increased, but the number of jobs fell.

Estimates of the impact also vary across *groups of workers*. The job losses resulting from an increase in the minimum wage in Brazil and Mexico seem to have particularly affected marginal groups such as women, youth, and low-skilled workers. It is supposed that this impact depends on the level of the minimum wage relative to the wages of these groups (World Bank 2006). In Chile, an increase in the minimum wage appears to have reduced employment opportunities among youth and the unskilled and, thus, especially unskilled youth, while promoting the employment of skilled and older workers (Montenegro and Pagés 2003). The minimum wage also appears to be responsible for much of the increase in long-term unemployment among the unskilled population in Bulgaria and Lithuania (Rutkowski 2003a, 2003b). Similarly, experience in Mexico suggests that the erosion of the minimum wage in the 1990s boosted employment among women (Feliciano 1998). Some countries also experimented with subminimal wages for apprenticeship, which seems to have improved employment opportunities for young graduates in Chile (Gill, Montenegro, and Domeland 2002).

While most of these studies use data on the formal sector, there are at least three studies that use the same methodology to look at the employment effects of changes in the minimum wage in the *informal sector* (Lemos 2004a for Brazil; Gindling and Terrell 2004a for Costa Rica; Jones 1998 for Ghana). Using microdata for Brazil, Lemos finds evidence of adverse employment effects in both the formal sector and the informal sector, challenging standard two-sector models. Her results are consistent with a sizable lighthouse effect. Similar effects are also found by Gindling and Terrell for Costa Rica who, perhaps surprisingly, also discovered evidence that the minimum wage compresses wage distribution in the informal sector more than in the formal sector. Yet, no wage effect of the minimum wage was found for the self-employed. In contrast, Jones (1998) found that the effects of the minimum wage in the informal sector

in Ghana appear consistent with the standard mechanism of the traditional two-sector model.

*Individual longitudinal data* make it possible to follow the labor market histories of persons whose wages are at or close to the minimum wage. Recent studies in this area find that changes in the minimum wage have a significant impact on employment among these workers. Nevertheless, there is no agreement over the direction of these changes. Abowd et al. (1999) found that, in France, an increase of 1 percent in the minimum wage reduces the employment probability of workers on minimum wage by 1.3 percent among men and 1.0 percent among women. In the United States, a reduction by 1 percent in the minimum wage increases the employment probability of affected workers by 0.4 percent among men and 1.6 percent among women. Portugal and Cardoso (2001) found different results using the same type of methodology. They exploited legislative changes in the minimum wage in Portugal in 1987. The minimum wage was raised by 50 percent for adolescents aged 16 to 18 and 33 percent for youths 18 and 19. They found that the hikes had a dampening effect on hiring, but that those young people who found jobs had a greater tendency to keep them. In other words, Portugal and Cardoso observed fewer departures from employment, and this partly offset the fall in hiring.<sup>23</sup> Using longitudinal data from three contrasting individual data sets, Stewart (2004) found that the introduction of the minimum wage in the United Kingdom had an insignificant effect on the employment probability of low-wage workers.<sup>24</sup> Indeed, overall, the minimum wage appeared to have potentially significant effects on the probability of being hired or of losing a job. However, it does not invariably have a positive effect on the probability of job loss among the population affected by the minimum wage.

### ***Effects on the wage level, the average wage, and wage distribution***

Empirical evidence suggests that the introduction of or increase in the minimum wage has considerable spillover effects on the level of wages of workers further up the earning distribution. For instance, studies in Brazil, Colombia, and Mexico show that a 10 percent increase in the minimum wage results in a 1–6 percent increase in average wages (World Bank 2006). This appears to be caused by the fact that the minimum wage seems to be used as a more general unit of account or “numeraire,” for instance in quoting wages or monetary contracts in general, and, hence, the minimum wage influences wages throughout the earnings distribution. For example, in Bolivia, the effects of a change in the minimum wage have echoed up the wage distribution; 60 percent of the rise has

been transferred to wages around the minimum wage, and 38 percent to wages around four times the minimum wage (Maloney and Mendez 2003). In Indonesia, a doubling of the minimum wage led to an estimated 10 percent increase in average wages (Rama 1996).

However, empirical evidence from Latin America suggests that some groups of workers benefit disproportionately from increases in the minimum wage and that this has important distributional implications. For example, analyses in Brazil and Mexico suggest that minimum wage increases benefit men more than women throughout the wage distribution. A 10 percent increase in the Mexican minimum wage led to a 10–36 percent increase in men’s wages, but only to a 0–10 percent increase for women (World Bank 2006). Similarly, in Mexico, adults with wages around the minimum wage are found to benefit more from minimum wage increases than do the young in the same earnings category.

The minimum wage appears also to operate somewhat in the informal sector in many countries of Latin America, including Brazil, Chile, Colombia, Ecuador, El Salvador, Guyana, Mexico, Nicaragua, Panama, Paraguay, Peru, Venezuela, and Uruguay (World Bank 2006). In Brazil, there is evidence that the minimum wage has a strong influence on the informal labor market and acts as a “voluntary” reference wage. Over 20 percent of wage adjustments in the informal sector were exactly equal to the minimum wage adjustment after the launching of the Real Plan, September 1994 to May 1995 (Amadeo, Gill, and Neri 2002). In Costa Rica, the minimum wage compresses the wage distribution in the informal sector more than in the formal sector, but does not have wage effects among the self-employed (Gindling and Terrell 2004a). Similarly, there does not seem to be evidence of a strong lighthouse effect among the self-employed in Bolivia; this might be related to the fact that the self-employed may adjust their earnings frequently to avoid inflation erosion (Maloney and Mendez 2003).

### ***The effect of minimum wage reforms on income distribution and poverty***

One way of assessing whether the minimum wage is actually enforced is to plot the earnings of individuals as a histogram. The position and shape of the histogram provide information on the extent of compliance with the minimum wage. If there had been no government intervention in the labor market, one would expect the wage distribution to be relatively smooth, reflecting the underlying distribution of skills among workers. On the other hand, if employers actually enforce the minimum wage, workers who would have earned less than the minimum are no longer employed, and the distribution is truncated. The fact that some workers

have lost their jobs should create a spike in the wage distribution that is relatively close to the legally imposed minimum. If there is no spike or if the spike lies significantly to the right or the left of the minimum wage, the data indicate that the minimum wage is having little “bite.” This empirical methodology is often used to provide a first assessment of the impact of a minimum wage. Most studies on developing countries *find evidence of a spike* in the wage distribution that corresponds to the minimum wage. This is a first, visual effect of the ability of the minimum wage to compress the earnings distribution. This effect appears to occur in most developing countries in Latin America and in some transition economies.<sup>25</sup>

Particularly interesting is the search for a wage spike in the informal sector. Since the minimum wage is not binding in that sector, one would expect to find no spike, but, if the lighthouse effect is relevant, one may find a spike in the wage distribution also in the informal sector. The lighthouse effect is precisely what Lemos (2004a) finds in her study of the impact of the minimum wage in the formal and informal sectors of the Brazilian economy. Similar results have also been found in other Latin American countries (World Bank 2006).

The overall impact of a reform on earnings inequality seems to depend on the initial level of the minimum wage. In Latin America, increases in a high minimum wage have been found to boost inequality, while increases in a relatively low minimum wage reduce inequality (World Bank 2006). The decrease in the real minimum wage in Brazil and Mexico in the 1990s has been blamed for a large share of the increase in overall inequality. Thus, the decrease was responsible for 4.8 percent of the increase in inequality in the formal sector and 18.4 percent in the informal sector in Brazil (Rodrigues and Menezes-Filho 2004). Similarly, a study of 121 countries over the period 1970–2000 shows that the minimum wage (relative to per capita income) tends to worsen income inequality (Calderón, Chong, and Valdés 2004).

On the other hand, empirical research in the United States generally concludes that the minimum wage reduces wage inequality (Brown 1999) and that an increase in the minimum wage also reduces wage inequality. DiNardo, Fortin, and Lemieux (1996) and Lee (1999) suggest that the fall in the real value of the minimum wage contributed significantly to rising wage inequality in the United States in the 1980s. DiNardo, Fortin, and Lemieux (1996) look at the evolution of the distribution of wages between 1979 and 1988 and find that the fall in the minimum wage explains one-quarter of the rise in the standard deviation in the distribution of men’s wages and 30 percent of the standard deviation for women. Lee (1999), for his part, estimates that the shrinking minimum wage over this period

explains 70 percent of the increase in the ratio of average fifth-decile wages to average first-decile wages.

Evidence from the United States suggests that the net effect of a minimum wage increase on *poverty* is very small; only 4.1 percent of the group was lifted out of poverty, while 3.9 percent of the previously non-poor fell into poverty as a result of the policy (Neumark and Wascher 1997). One possible explanation lies in the fact that earners of the minimum wage are typically distributed across the broader population (including in middle-income households) rather than only in low-income households. Hence, some of those who lose their jobs might live in households that have other substantial sources of income that can help maintain the newly unemployed individuals within the non-poor household. Similar results have also been obtained through a simulation exercise in the United Kingdom that used data from the family-expenditure survey and Polimod, a tax-benefit microsimulation model (Sutherland 2001). Findings from this simulation suggest that the minimum wage is not an efficient method for targeting poverty in the United Kingdom because it benefits the same proportions of the poor and the non-poor. In addition, poverty rates appear not to be very sensitive to the level of the minimum wage, and the introduction of the minimum wage appears to have only a small impact on the overall poverty rate, a potential reduction of only 1.2 percent.

For the minimum wage to have a significant impact on poverty, it needs to be higher than the subsistence minimum for wage earners and their dependents. However, the minimum wage provides for the basic needs of one worker, plus one dependent in only 7 of the 17 countries in a study on Latin America and the Caribbean (World Bank 2006). A look at both the increased wages among those household members who kept their jobs and the fall in earnings among those who lost theirs reveals that the increase in the minimum wage had some impact on wage poverty rates in Colombia, but not in Brazil (Arango and Pachon 2003). A disaggregation among the poor, who represent a large share of the population in these countries, shows, however, that the poorest do not benefit. Rather, the main beneficiaries are households near the poverty line. The poorest 25 percent in Colombia are not helped at all, which might be because the wage and unemployment effects cancel each other out or because the minimum wage laws do not have effects on this part of the population. In Brazil, the bottom 30 percent of the income distribution actually experiences wage losses, while poor households in higher brackets do not benefit. These results are confirmed by Carneiro (2004), who suggests that the shift of employment from the formal sector to the informal sector following the increases in the minimum wage in Brazil from 1982 to 2002

was largely responsible for the rise in poverty over that period. Similarly, evidence from Indonesia suggests that increases in the minimum wage may have worsened the poverty situation there (Mason and Baptist 1996).

In contrast, an analysis in four African, five Asian, and thirteen Latin American countries shows that the minimum wage does reduce poverty as measured by headcount, the poverty gap, or calorie intake. These effects are similar in the various regions, though they are more marked for urban poverty relative to rural poverty. However, since the minimum wage is also associated with higher unemployment, the reduction in poverty may be offset by losses in efficiency over the long term (Lustig and McLeod 1996).

### **Employment protection legislation**

Assessing the impact of a specific reform in employment protection legislation is not easy. In the absence of evaluations using natural experiments, most empirical regularities are revealed through cross-country comparisons rather than through full-fledged policy evaluation. Researchers have used statistical methods to compare the effects of a reform on treatment groups of workers, as well as control groups. This is always done using microdata on firms and workers. A good example is the work of Kugler (2000, 2004) on the Colombian reform. The identification strategy of this type of analysis consists of exploiting the change over time in labor market legislation, together with the variability in coverage across groups. While such studies broadly confirm the empirical regularities, they provide much sounder economic analyses. Another example of this type of study is Acemoglu and Angrist (2001).

### ***Effect on employment levels***

According to the theoretical wisdom, the overall effect of employment protection legislation on employment should be limited. Indeed, stricter legislation is expected to reduce labor turnover, which would translate into higher employment rates during periods of recession (since firms cannot adjust their labor force downward) and lower employment rates during periods of expansion (since firms do not adjust for fear of subsequent recessions). Hence, the net impact of reforms is likely to vary according to economic cycles.

Evidence from cross-country time-series data on OECD countries tends to find that stricter employment protection legislation has either a negative or an insignificant impact on employment. Similarly, the effect on unemployment is ambiguous. However, evidence based on disaggre-

gated data for single countries, which permit the capture of more variations in regulatory policies, suggests that job-security regulations have a negative effect on employment.<sup>26</sup>

In Peru, the use of severance payments is found to have a negative effect on the level of employment, and labor demand appears to adjust more slowly to economic cycles. Between 1987 and 1990, a 10 percent increase in dismissal costs reduced long-run employment rates by an estimated 11 percent, keeping wages constant (Saavedra and Torero 2000, 2003). Evidence from Argentina also points to a negative relationship between employment protection legislation and employment, with a 10 percent increase in dismissal costs, leading to a 3 to 6 percent decrease in employment rates (Mondino and Montoya 2003). Overall, the country-specific evidence from Latin America consistently points to a negative impact on average employment rates by employment protection legislation, although a cross-sectional analysis of time-series data on a pool of countries does not yield robust results (Heckman and Pagés 2003). Similarly, in South Africa, 39 percent of large manufacturing firms reacted to stricter legislation by reducing the level of hiring or substituting capital for workers, which suggests that the legislation had a negative impact on employment levels.<sup>27</sup> An equally strong negative relation emerges in Croatia, where excessive legislative controls have been identified as the only major reason for high levels of unemployment (Rutkowski 2003c).

In the longer term, legislation may have an impact on the type of technology that firms select. An increase in legislative controls could, in the long run, lead firms to invest in labor-saving technologies, thereby raising the capital-labor ratio and lowering employment. This phenomenon seems to be confirmed by a comparison of France and the United States in the 1980s and 1990s (Caballero and Hammour 1998). Capital-labor ratios are larger in France than they are in the United States, and the evolution of profit shares is consistent with this finding (Blanchard 1997). The evidence from South Africa presented in Table 3.3 also points to substitution, with 39 percent of large manufacturing firms responding to stricter legislation by replacing workers by capital.

### ***Effects on employment flows***

Overall, radical reforms in employment protection legislation affect the cost for firms of the worker separations the firm may initiate. A first direct effect is that strict legislation pushes the firms to hold on to marginal jobs and delay labor adjustment (that is, they hoard labor). Stricter legislation also leads firms to anticipate more costly labor adjustments in the future

**TABLE 3.3. Cumulative Employment Response of Firms in the Greater Johannesburg Metropolitan Area to the Stricter Labor Policies of 1995–9, 1999***percentage share of firms*

	<i>Large manufacturing</i>	<i>Large tourism</i>	<i>Large information technology</i>
Hire fewer workers	39.2	25.9	7.0
Substitute capital machinery for workers	38.9	7.3	14.0
Hire more temporary than permanent workers	41.6	27.9	14.0
Rely more on subcontracting	33.5	27.8	19.0
Improve labor relations	29.6	26.0	9.0
Increase labor productivity	11.9	18.7	—

*Source:* Chandra and Nganou 2001.

in response to adverse shocks, which reduces their incentive and propensity to hire. This suggests that stricter legislation reduces turnover (hiring and firing) within firms and increases the duration of unemployment. As a result, any reform that reduces the stringency of employment protection legislation should induce an increase in turnover within firms. This assessment is strongly supported by empirical studies in OECD countries. For instance, Scarpetta (1996) finds that the effect of strict legislation is more severe on long-term unemployment than on average unemployment.

The reduction in the costs of firing in Peru since 1991 through fewer job-security regulations, the introduction of temporary contracts, and changes in the severance payment regime has led to a growth in turnover, especially in the formal sector, among blue-collar workers and temporary workers (Saavedra and Torero 2000, 2003). Similarly, the introduction of fixed-term contracts and employment trial periods in Argentina led to a sharp increase in labor turnover, increasing hazard rates during trial periods by 40 percent, without an offsetting decrease in long-term employment (Hopenhayn 2001).<sup>28</sup> In Colombia, a loosening of regulations in 1990 increased the dynamism of the labor market by raising entry and exit rates into and out of unemployment, especially in the formal sector and among large firms (Kugler 2000).

### ***Effects on types of employment***

Marginal reforms can have an impact on types of employment. For instance, a reform in employment protection legislation that increases the availability of fixed-term contracts will increase the incentive for firms

to hire new workers on temporary contracts and wait to lay off employees until the expiration of temporary contracts. Hence, such marginal reforms can lead to the establishment of a dual labor market wherein a stock of protected workers hired under a full employment protection regime is accompanied by a fringe of flexible workers hired on temporary contracts. These temporary contracts thus act as a sort of buffer to shocks in the output market (Blanchard and Landier 2002).

The use of temporary contracts varies across countries, but it is substantial in some cases. For instance, in Spain, the share of workers hired on temporary contracts is now as high as 30 percent (Dolado, García-Serrano, and Jimeno 2002). The share of temporary contracts in formal salaried employment in Lima rose from under 20 percent in 1991 to 44 percent in 1997 after the red tape and restrictions on temporary contracts were reduced (Saavedra and Torero 2000). In Argentina, the rise in hiring on temporary contracts was associated with a substitution away from longer-term employment (Hopenhayn 2001). In Colombia, growing employment turnover following a relaxation of employment protection legislation resulted in greater reliance on temporary contracts, as well as less job security for permanent workers (Kugler 2000). Evidence on large firms, especially manufacturing firms, in the metropolitan area of Johannesburg also points to a shift to temporary contracts as a result of the passage of stricter legislation in 1995–9, as shown in Table 3.3. More generally, the introduction of strict legislation in India and Zimbabwe appears to have been followed by a substantial decline in the demand for employees, with a clear causality relation, at least in the case of India (Fallon and Lucas 1991).

### ***Effect on the demographic structure of employment***

Similarly, stricter legislative regimes can increase the marginalization of outsiders. While average employment is not necessarily directly affected by strict legislation, stricter employment protection legislation tends to be associated with fewer jobs for newcomers to the labor market (youth, low-skilled workers, women, and so on). This can be explained partly by the fact that the value of severance payments rises with wages and with seniority, making it more expensive for firms to dismiss older or more well paid workers. For instance, in the OECD and in Latin America, more stringent legislation is found to increase youth unemployment more than average unemployment (Heckman and Pagés 2000 and Scarpetta 1996). The evidence for differentiated impacts on men and women is less uniform. Heckman and Pagés (2000) find that stricter legislation is associated with lower employment rates among women in the OECD, but with

higher employment rates among women in Latin America. Evidence from Chile suggests that stricter regulations reduce the employment opportunities of the young and the unskilled (thus, especially unskilled youth). It also finds that stricter regulations may force some workers, particularly women and the unskilled, out of wage employment and into self-employment (Montenegro and Pagés 2003).

### ***Effect on formal employment***

To the extent that different employers are subject to different rules (either because of their formal or informal status, or because of their sector), reforms in employment protection legislation can influence the sectoral distribution of employment. In India, stricter employment protection (in favor of workers) is found to decrease registered manufacturing output and employment (firms are registered in the formal sector once they reach a certain size) and increase unregistered (informal) manufacturing output, with no net effect on total output (Besley and Burgess 2004). Marquez (1998) finds that, in Latin America, more stringent protection is associated with a larger percentage of self-employed workers. Overall, however, the evidence is still mixed on this effect both in the OECD and in Latin America (Heckman and Pagés 2000).

### ***Effects on unemployment***

While the evidence suggests that stricter protection legislation has a negative effect on employment, the evidence concerning unemployment is ambiguous. Some workers appear to leave the labor market altogether because of reduced employment opportunities.<sup>29</sup> For example, the increased flexibility in hiring and firing introduced in Colombia is estimated to have decreased the unemployment rate by between 1.4 and 1.7 percent from the late 1980s to the early 1990s, a period of economic expansion. However, in contrast, the greater flexibility may also explain part of the surge in the unemployment rate during the late 1990s, a period of economic recession (Kugler 2000). A study of the effect of the 1990 Bolivian reform shows that the duration of unemployment decreased as a result of more relaxed legislation and that exit rates from unemployment into formal employment (especially into large firms) rose more than exit rates into informal employment (Kugler 2004).

### ***Effects on wages***

While it is difficult to isolate the effect of employment protection legislation on wages, most of the empirical work on wage determinants among temporary workers finds unexplained wage differentials. In other words,

for a given tenure, education, gender, occupation, and experience, temporary workers receive lower wages. Such residual differentials are consistent with the prepayment effect outlined above (OECD 2002).

### ***Effect on productivity***

Employment protection legislation increases job security and can therefore be expected to reduce the incentive for workers to take extra effort, which, in turn, reduces labor productivity. This applies as long as the cost of supervision is excessive so that the risk of disciplinary dismissal is limited. The effect of reforms also ultimately depends on the actual enforcement of the reform. For instance, the effectiveness of legislation depends partly on how the norms are interpreted by the courts.

In an indirect way, stricter legislation reduces the reallocation of human capital from ailing sectors to expanding sectors, resulting in an inefficient allocation of labor. More relaxed legislation may allow for a better allocation of workers among firms since the cost of experimentation with new, potentially better matched workers is lower. This may have an impact on average productivity in the economy and on growth.

Strict legislation will also likely hamper the speed at which economies adjust to shocks. Estimates based on 60 countries for the 1980s and 1990s show that, in countries where the rule of law is well established (that is, better enforcement), a shift from a low level of job security (20th percentile of the distribution in the 60 countries) to a high level of job security (80th percentile) cuts the speed of adjustment to shocks by one-third and reduces annual productivity growth by about 1 percent. In contrast, such a shift in countries with poorer enforcement does not have much impact on productivity growth (Caballero et al. 2004).

### ***Effect on poverty***

To the extent that reforms in employment protection legislation have an impact on types of employment and relative wages, they can be expected to have an impact on poverty if the people who are affected are living near the poverty line. The evidence is scarce on this type of impact. Besley and Burgess (2004) find that, in India, stricter legislation tends to reduce the size of the formal or registered manufacturing sector, which affects the urban poor. They estimate that poverty would have been 11 percent lower (that is, 520,000 fewer poor) in the state of West Bengal if the state had not passed stricter legislation. Conversely, poverty would have been 12 percent higher (that is, 640,000 more poor individuals) in the state of Andhra Pradesh if the state had not relaxed the relevant legislation.

## Unemployment benefits

In the absence of evaluations of the impact of unemployment benefits based on natural experiments, the most solid empirical evaluations of the impact of the benefits and the relevant reforms have been produced through microeconomic studies. An alternative method of assessing benefit reform at the aggregate level is to use difference-in-differences techniques to compare labor market performance in reforming and non-reforming countries before and after the policy changes.

### ***Effects of increasing the length and generosity of unemployment benefits***

A key predictor related to the baseline transmission mechanism revolves around the links between the generosity of unemployment benefits and *long-term unemployment*, which is measured as the share in all the unemployed of those who have been unemployed for more than one year. Cross-country tabulations display a positive association between the maximum duration of unemployment benefits and long-term unemployment (Boeri, Layard, and Nickell 2001).<sup>30</sup> However, several recent studies suggest that the causality may run the other way: governments in countries with a higher incidence of long-term unemployment are subject to pressure to increase the maximum duration of benefits. Indeed, in the United States, regional variations in the maximum duration of benefits tend to occur in parallel with increases in the duration of unemployment in some states (Card and Levine 2000). Indeed, Lalive, van Ours, and Zweimueller (2002) show that this policy endogeneity may lead one significantly to overstate the negative effects of benefits on the duration of unemployment. The microeconomic literature can deal more effectively with these “policy endogeneity” problems. It suggests that the duration of unemployment benefits has a strong effect on the flows from unemployment to employment. The literature draws on so-called duration analysis (Kiefer 1988) and points to the negative effects of the duration of benefits on unemployment outflows even when controlling for regional characteristics and cyclical conditions (Atkinson and Micklewright 1991; Krueger and Meyer 2002). Similarly, the reduction in the possible duration of unemployment benefits undertaken in Slovenia in 1998 appears to have had a significant positive effect on the exit rate out of unemployment to employment and to other categories of activity (Van Ours and Vodopivec 2005a, 2005b).

Overall, there is little doubt that generous unemployment benefits increase the duration of unemployment. Nonetheless, estimates of the effects of benefit generosity on unemployment duration should be viewed

with caution. The role played by policy endogeneity suggests that these estimates may be more fruitfully viewed merely as upper bounds to the elasticity of unemployment outflows with respect to benefit generosity.

The argument centered on the key transmission mechanism holds that greater benefit generosity is correlated with potential reductions in the *employment rate* of groups exhibiting elastic labor supply (via the effects on the incentives for job-seeking) and groups represented by unions (via the effects of unions on labor demand). In accordance with these predictions based on the key transmission mechanism, estimates of aggregate employment and unemployment equations (Nickell 1997; Blanchard and Wolfers 1999; Scarpetta 1999) point to the existence of a mild, but statistically significant and positive effect of the generosity of unemployment benefits on unemployment. This conclusion seems also to apply to the transition countries of Europe and Central Asia (Alam et al. 2005).

Evidence supplied through surveys of individuals and households suggests that the reservation wage of job-seekers is positively affected by unemployment benefit receipts (as predicted by the above argument based on the transmission mechanism), and this puts upward pressure on *wages*.<sup>31</sup> Estimates of earnings functions also find that the effect of unemployment benefits on wages is positive, although many different channels could generate this result.

### ***Effects of employment on conditional incentives***

Evidence related to both the earned income tax credit in the United States (Eissa and Hoynes 1998) and the working family tax credit in the United Kingdom (Blundell and Hoynes 2001) indicates that the programs have lowered employment rates among married women with working spouses. The most relevant example in Europe—at least in terms of take-up rates—is the Dutch SPAK measure (see Doudeijns, Einerhand, and Van de Meerendonk 2000), which allows employers to reduce their contributions on low wages.<sup>32</sup> The amount of the reduction declines as the wage rises, and the reduction ceases to be available at 115 percent of the statutory minimum wage. Evaluations based on general equilibrium models of the Dutch economy (De Mooij, Graafland, and Bovenberg 1998) have predicted a total increase in employment of between 1 and 5 percent among the low skilled. Evaluations of similar programs in Belgium and France report significant effects on employment. On the basis of individual data on firms, Crépon and Deplatz (2001) estimate the number of jobs created at between 255,000 and 670,000. Sneessens and Shadman-Metha (2001) estimate that, in Belgium, a cut of 21 percent in employer contributions for unskilled jobs may increase total employment of the

unskilled by 6.7 percent. All these estimates are based on different estimates of demand and supply elasticities.

### ***Effects of employment activation policies***

The jury is still out on which employment activation policies work and which do not. However, there is a consensus that different categories of individuals—youth, married women returning to the labor market, the long-term unemployed—respond more readily to different activation policies. The experimental evidence on activation policies is confined, regrettably, mostly to the United States, and nonexperimental evidence exists for the United States and some European countries. Nevertheless, for the most part, the picture that emerges is quite consistent and, at a minimum, allows some policies to be ruled out because they are not effective.<sup>33</sup>

A key result is that employment activation policies should be different for people receiving unemployment insurance and people receiving unemployment assistance. This is partially caused by differences in the average characteristics of the two groups of recipients.<sup>34</sup> Recipients of unemployment assistance include many older individuals with long unemployment spells whose employability is questionable. The evidence on how these individuals might be helped is disappointing because no strategy seems effective. To avoid wasting human and financial resources, it is therefore important to test the willingness of these individuals actively to seek work. Hence, the best strategy for recipients of unemployment assistance may be to promote slots in active labor market programs, such as training programs, and, if necessary, subsidized jobs or job-creation schemes; however, expectations should not be boosted. The strategy should be understood mainly as a screening device. A job-seeker's refusal to participate might be discouraged by providing for reductions in the duration of unemployment assistance or outright elimination of the benefit.

Australia has experimented the most with policies aimed at helping the long-term unemployed. The Australian New Start allowance for the long-term unemployed emphasized "activity agreements," which funded paid work experience or unpaid volunteer work proposed by the recipient. This was part of a "case management" approach involving greater administrative oversight of the long-term unemployed and more frequent interviews with the public employment service. The strategy proved costly, and the results were far from encouraging. In 1996, the approach was scaled back by the new Labor government, and the intervention was increasingly decentralized to private and not-for-profit organizations, with premiums for the placement of older workers.

Empirically, activation policies for women returning to the labor market have been found to be the most successful, especially when they take the form of assistance in job-seeking, counseling, and training directed at facilitating an immediate return to employment. Successful policies for other groups of unemployment assistance beneficiaries with limited labor market experience, such as unemployed youth, have proved elusive. In particular, there is evidence that training per se has very little effect on this group; constant monitoring and testing of employment activity are crucial.

For the young unemployed, the most effective scheme would seem to be the British New Deal, which is the most articulated effort to deal with this problem to date. Key features of the New Deal are (1) the combination of lump-sum wage employment subsidies and assistance in job-seeking and on-the-job training; (2) the screening during the initial four-month gateway period to separate out individuals who tend to be unemployable and minimize deadweight costs; and (3) a division of the young unemployed into two groups according to age and the duration of the unemployment spell.

Unemployment insurance recipients are individuals who experience relatively short unemployment spells and whose employability (or lack thereof) must generally still be assessed. Activation strategies aimed at these individuals therefore rely less heavily on employment activation and more on assistance in job-seeking and testing, which have proved to be among the most effective instruments.

### ***Effects of job-seeking requirements***

Evidence demonstrates the usefulness of job-seeking assistance among women and recipients of benefits who have recently become unemployed. Over and above the effects of financial incentives, the Canadian Self-Sufficiency Project and the Minnesota Family Investment Project in the United States (both targeted at welfare recipients) were designed specifically to test the *incremental* effects of policies aimed at an early reintegration into employment, primarily assistance in job-seeking, then short-term training and job counseling. The incremental effects of these policies on employment seem large: up to a 7 percentage point increase in employment rates in the case of the Self-Sufficiency Project and nearly a 10 percentage point increase in the case of the Minnesota Family Investment Project. There are also positive effects on earnings. Although these estimates should be interpreted as upper bounds, assistance in job-seeking and related activities are starting to be regarded as cost effective.

Other experiments conducted in cooperation between several states and employment services in the United States have achieved considerable cost savings by augmenting job-seeking requirements. Thus, in Switzerland, the United Kingdom, and the United States, individuals must now fill out a minimum number of job applications in a given period (usually determined case-by-case by the public employment service). Experimental evidence (mainly from the state of Maryland) shows that job counseling has a substantial effect on outflows from unemployment to jobs. Significantly, most of the increase in exits from unemployment occurred shortly before a compulsory four-day training workshop on job hunting, which represented a rise in the opportunity costs of drawing unemployment benefits. Attendance at the workshop itself did not have a significant effect on outflow rates. In other words, it was the “help and hassle” approach involved in the initiative that stimulated exits from unemployment, rather than the job-hunting training scheme per se.

## CONCLUSIONS

Assessing the potential distributional impacts of labor market interventions and reforms in labor market institutions is not a simple task. This is due to a number of factors.

First, in evaluating the potential impact of interventions and reforms on income distribution, one must distinguish between the distribution of earnings and the distribution of income. The former is defined at the level of individuals and by focusing only on employed workers. The latter is usually defined at the level of households and depends on the total labor income of all household members, plus income from other sources.

At least in the case of the policies described in this chapter, the difficulty arises from the fact that the empirical evidence suggests that labor market policies protect the prospective earnings of workers in the sectors that are covered at the expense of employment opportunities in that sector and earning levels in the rest of the economy, that is, the sectors that are not covered, whether formal or informal. As long as such an imbalance exists between earnings and employment opportunities in the covered sector, the risk is that labor market policies may lead to greater inequality and more poverty. This is particularly true in the case of labor market policies that are not directly targeted at low-income earners, but it also applies to policies designed to protect the most vulnerable workers, such as workers at minimum wage.

An increase in the minimum wage can have both a positive and a negative effect on inequality in household incomes. First, an increase in

the incomes at the lower end of the range of the formally employed typically tends to reduce inequality in individual earnings. However, it might also result in a reduction in employment among low-paid workers, for whom the minimum wage is binding, or in the transfer of some of these workers to the uncovered, lower-pay informal sector. This could increase inequality in labor incomes both among individuals and at the household level, especially if workers at the minimum wage live in households with a high proportion of low-skilled, potentially low-pay individuals. The overall direct effect on income inequality depends on labor market conditions, demographics, and household composition. The effects are also compounded by indirect changes in the uncovered sector. If labor is mobile across sectors, then the standard covered-uncovered adjustment mechanisms will come into play, and an increase in the minimum wage will lead to an increase in earnings inequality.<sup>35</sup> In this situation, the overall impact on the distribution of household incomes will depend on the employment dynamics operating between the covered and uncovered sectors, as well as on the impact of the reform on the two segments of the labor market.

Similarly, reforms of the minimum wage are also expected to have a typically ambiguous impact on the *poverty rate*. An increase in the minimum wage, for example, will usually boost the earnings of low-paid workers who maintain their jobs, and, *ceteris paribus*, this will bring the poverty rate down if the individuals are the only income earners within their households or if all low-paid earners within households maintain their employment at the prereform level. However, the increase in the minimum wage is also likely to reduce employment in the covered sector, and this will result in lower labor incomes among households if any wage earners in the households lose their jobs as a result of the policy or are forced to transfer to the lower-paying uncovered sector. This may increase the vulnerability to poverty of households that are close to the poverty line.

Thus, the impact of labor market policies and reforms of these policies on the distribution of household incomes and on poverty depends crucially on the existence of a trade-off between labor market protection and employment, that is, a trade-off between intervention and efficiency. This is not as clear cut as the advocates of liberalization would like one to believe. The arguments presented in this chapter show that both intervention and the lack of intervention may lead to inefficient and inequitable outcomes.

The desirability of a particular sort of labor market intervention therefore depends crucially on the type and characteristics of the policy.

Some policies and intervention designs generate improvements on both efficiency and equity grounds; others result in a trade-off between efficiency and equity, and still others lead to a definite worsening in both areas. Similarly, it is unwise to argue in favor of or against a particular reform without careful evaluation of the potential impact of the new policy on labor market efficiency, income distribution, and poverty.

This chapter has provided the tools required to conduct such an evaluation by (1) identifying the main channels through which the redistributive and poverty impacts of three labor market policies—the minimum wage, employment protection legislation, and the unemployment benefit—affect earnings and household incomes and (2) reviewing the existing empirical evidence on the magnitude and direction of the impacts of these policies on each link in the chain. The evidence points to a number of cases in which the labor market interventions analyzed here may have negative effects on income equality and may increase poverty rather than reducing it. However, this is clearly not the case across the board. This leaves policymakers faced with the challenge of designing interventions that strike the right balance between reducing income inequality and curbing poverty on the one hand, while continuing to protect the living standards of workers. This can only be done effectively by mastering the factors that lead to the existence of tensions between labor market interventions and employment. It requires policies that are at once pro-growth and pro-equity. Some of the innovative policies introduced recently by a number of countries in Central Europe and Latin America to maintain the incomes of the unemployed seem to answer this challenge. Among these are conditional transfer programs and employment activation programs.

## NOTES

1. The theory of the second best assumes that, if one of the conditions necessary to achieve Pareto optimality is missing, then the “second best” position can only be reached by departing from all the other Paretian conditions. Pareto efficiency is defined as the efficiency of a market that is unable to produce more from the same level of inputs without reducing the output of another product.
2. The insider-outsider theory, developed by Lindbeck and Snower (1989), argues that existing workers, *insiders*, enjoy a relatively advantageous position and expropriate rents from their employers thanks to the high barriers to employment faced by unemployed and entrant workers, the *outsiders*. However, in this chapter, “insiders” is used to refer to the workers covered by labor market regulations, and “outsiders” is used to refer to the unemployed

or to those people working in uncovered jobs in the formal or the informal sectors. This distinction is somewhat better defined than that between formal and informal employment.

3. The focus of the chapter is on statutory regulations and interventions. This is so despite the fact that, in many countries, these types of policies have been replaced through voluntary negotiations and agreements between labor and managers; these act in a way very similar to the mandatory steps described. The voluntary agreements are not explicitly analyzed here.
4. Other types of labor market institutions and regulations that are not analyzed here include labor unions, labor standards, wage-setting laws (other than minimum wages), collective bargaining, the constraints imposed in the context of privatization (for example, no retrenchment), pensions, active labor market programs (such as public works), the public sector's role in the labor market, training and retraining programs, microfinance and unemployment lending, and payroll taxes.
5. For instance, Scarpetta (1996) finds that the size of the impact of strict employment protection legislation on unemployment depends on the wage-bargaining system. Such interactions are not systematically reviewed here.
6. For an extensive review of different types of employment protection legislation and the relative advantages, see Betcherman, Luinstra, and Ogawa (2001).
7. This can represent a substantial cost when the period is long. For instance, prior to the 1999 reforms in Brazil, more than 6 percent of all salaried workers (about 2 million workers) filed lawsuits every year, and the average dispute took almost three years. (This was cut in half by the reforms; see World Bank 2002.) The number of cases and the length of court hearings vary greatly in the OECD. Up to 20 percent of layoffs become subjects of court proceedings in France, with an average dispute lasting over a year (OECD 2004).
8. Of course, these laws only formally apply to workers in the formal economy, which often represents a very small share of the total number of workers.
9. The *working poor* are those workers who are employed full time and, nevertheless, appear to be living close to the poverty line.
10. Fondazione Rodolfo DeBenedetti, <http://www.frdb.org>.
11. Labor market monopsony refers to the situation wherein a dominant employer is, in essence, a single "buyer" of labor services in a particular segment of the labor market. Under this condition of demand-side monopoly, the monopsonist employer pays lower wages and employs less labor than would employers in the case of perfect competition.
12. This distinction is somewhat sharper than that between formal and informal labor markets as highlighted by the theory of labor market duality.
13. This prediction requires that labor mobility be perfect between the two sectors.
14. The poverty rate is usually measured as the proportion of individuals whose *incomes* are less than a threshold value referred to as the *poverty line*.
15. The best description of this mechanism is contained in the work of Bentolila and Bertola (1990) and Bertola (1999). Ljungqvist (2002) studies

- this transition mechanism through a variety of models and finds that it is quite robust.
16. Spain is the most prominent example in this respect. There, the share of workers hired on temporary contracts is now as high as 30 percent (Dolado, García-Serrano, and Jimeno 2002).
  17. See Garibaldi and Violante (2002).
  18. So called from the properties of putty and clay. Putty can be molded as one might wish before it is baked, but, through baking, putty becomes hardened clay, and the shape can no longer be altered.
  19. When the elasticity of labor demand is larger than that of labor supply, the employment effect will be larger than the earnings effect.
  20. Crépon and Deplatz (2001); De Mooij, Graafland, and Bovenberg (1998); Doudeijns, Einerhand, and Van de Meerendonk (2000); European Commission 1999; Sneessens and Shadman-Metha (2001).
  21. See, for example, Carneiro (2004) on Brazil.
  22. Note that this type of equation is econometrically identified only if the firm is a price-taker in the labor market, so that the monopsonistic model does not apply. To insure proper identification, these studies often use a lagged value for the minimum wage.
  23. Note that this result is coherent with the prediction of the monopsony model, since it confirms the greater attachment of youth to their jobs when wages improve.
  24. The three data sets used were the labor force surveys, the British household panel survey, and the matched new earning surveys for the period after 1999.
  25. See Maloney and Mendez (2004) and Eriksson and Pytlikova (2004).
  26. For a summary and discussion, see Addison and Teixeira (2003) and Heckman and Pagés (2003).
  27. Firms in service industries, particularly in tourism, also reduced their hiring, as is evident in Table 3.3.
  28. Additional examples are summarized in Heckman and Pagés (2000).
  29. See Heckman and Pagés (2003) for a summary of the evidence.
  30. The best example is probably offered by transatlantic differences in unemployment rates. These differences can be almost entirely explained by the differences in long-term unemployment rates. Meanwhile, unemployment benefits in Europe are significantly more generous than those in the United States.
  31. The reservation wage is the lowest wage at which a job-seeker would consider a job offer.
  32. SPAK is short for *Specifieke Afdrachtskorting* (specific tax rebate).
  33. For a detailed review of the evidence on this issue, see Betcherman, Olivas, and Dar (2004).
  34. Unemployment assistance covers workers who have been unemployed for a long time and the other individuals without occupation, such as youths with no or limited labor market experience, mothers returning to the labor mar-

- ket after exhausting maternity protection, disabled individuals, and older, long-term unemployed who have exhausted unemployment assistance. Unemployment insurance covers other unemployed workers who have accumulated enough contributions to be eligible for unemployment benefits.
35. The potential negative impact is reduced if there is a lighthouse effect, since a higher minimum wage leads to an increase in wages in the market, whether covered or uncovered.

# Characteristics of the Minimum Wage in Selected Countries

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
<i>Europe and Central Asia</i>		
Albania	The national minimum wage rate is set in an order of the government.	The national minimum wage rate applies to all workers.
Bulgaria	The government sets the national minimum wage rate by decree.	The national minimum wage rate applies to all workers and employees.
Cyprus	There is no national minimum wage. The government sets minimum wage rates for selected low-wage occupations. These minimum rates are adjusted yearly.	Only workers in the occupations specified by the government.
Czech Republic	The government stipulates the national minimum wage rate in an official decree. It also sets 12 minimum tariff rates for different grades. The minimum wage is adjusted yearly.	The Labor Code applies to all employees except those who work for a company registered in the Czech Republic, but work and reside in a foreign country. Employees of a company with foreign capital interest may be excluded if the government specifies a regulatory framework that governs them.
Estonia	The minimum wage and the procedures to amend it are set by the government based on a bipartite agreement between worker and employer organizations.	The minimum wage rate applies to all workers employed under an employment contract.
Hungary	The minimum wage rate is determined by the government. The National Labor Council is consulted during the process, and minimum wage rates are subject to its agreement.	Minimum wage regulations apply to all, including public service officials otherwise exempt from the Labor Code. They apply also to employees of Hungarian employers working abroad, but not to foreign employers and their employees working in Hungary.
Latvia	Minimum wage rates are determined by the government.	The Labor Law of 2001 covers all employees and employers.
Lithuania	The government determines minimum wage levels according to the recommendations of a tripartite council.	Regulations apply to all workers employed in Lithuania or posted abroad by their employers. They do not apply to foreign employers who post employees to Lithuania.

## Annex 1: Characteristics of the Minimum Wage in Selected Countries

Coverage: variations in minimum wage, by categories	Level(s) <sup>a</sup>
<ul style="list-style-type: none"> <li>The government may establish a lower minimum wage rate for young workers to facilitate their entry into the workforce.</li> </ul>	PPP\$195.27 per month.
<ul style="list-style-type: none"> <li>During an apprentice's training period, which cannot exceed six months, the wage may not be less than 90% of the minimum wage.</li> <li>Piece-rate workers.</li> </ul>	PPP\$213.02 per month.
<ul style="list-style-type: none"> <li>The minimum wage order applies to shop assistants, clerks, nursing aids, and child-care workers.</li> </ul>	US\$618.00 per month for the first six months.
<ul style="list-style-type: none"> <li>A minimum wage rate that is slightly lower than the regular rate applies during the first six months of employment with a new employer.</li> </ul>	US\$657.60 per month after the first six months.
<ul style="list-style-type: none"> <li>When employers do not sign a collective agreement with trade unions, they must pay their employees at least the minimum tariffs for the grade of the employees.</li> </ul>	PPP\$466.48 per month.
<ul style="list-style-type: none"> <li>Employees between 18 and 21 years of age are entitled to 90% of the minimum wage for a six-month period. Employees under 18 are entitled to 80% of the minimum wage.</li> </ul>	
<ul style="list-style-type: none"> <li>Employees with partial disability pensions are entitled to 75% of the minimum wage. Employees with full disability pensions and disabled juveniles without pensions are entitled to 50% of the minimum wage.</li> </ul>	
	PPP\$384.75 per month.
	.
<ul style="list-style-type: none"> <li>The Labor Code provides that separate rates may be set for a specific field or area. In fact, no separate rates have been set.</li> <li>Minors, disabled employees, and part-time employees may receive less than the minimum wage only if a derogation is issued by the National Labor Council. No such derogation has been issued.</li> </ul>	PPP\$420.80 per month.
<ul style="list-style-type: none"> <li>A separate minimum hourly rate is established for workers under 18 years of age.</li> </ul>	PPP\$335.61 per month.
<ul style="list-style-type: none"> <li>The legislation provides that specific wage rates may be set for categories of employees and different branches of the economy. In fact, no specific rates have been set.</li> </ul>	PPP\$313.73 per month.

(continued)

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
Poland	The Tripartite Commission negotiates minimum wage levels by July 15 every year based on the government's proposal. If the commission does not reach a consensus, the government sets the minimum wage, which cannot be lower than what it proposed to the commission. The minimum wage is adjusted yearly, unless forecasted inflation is above 5% (adjusted twice a year).	The minimum wage applies to all employees in full-time employment.
Romania	The government sets a national minimum wage rate following consultations with social partners.	The Labor Code applies to all Romanians working in Romania or overseas if employed by a Romanian employer (unless the legislation of the host country is more favorable), and to foreigners working in Romania for a Romanian employer.
Russian Federation	The federal government establishes a national minimum wage rate. The Labor Code provides for social partnership involving mutual consultations on guarantees of employee labor rights and improvements to labor laws in general.	The national minimum wage applies to all nonqualified workers in an employment relationship.
Slovenia	The government sets the minimum wage rate by special regulation in accordance with a tripartite pay policy agreement. The Economic and Social Council of Slovenia is frequently the forum at which minimum wage negotiations take place.	The minimum wage applies to all employees in the private sector with no exception. All employers must pay a wage that is at least equal to the minimum wage.
Slovakia	The government sets the minimum wage rate by special regulation following the recommendation of social partners. The minimum wage is adjusted yearly.	The Labor Code applies to all employees, including those working for foreign employers, unless otherwise stipulated. Employees posted to another EU member state are governed by that state's regulations provided their stay exceeds one month and work exceeds 22 days in the year.

Coverage: variations in minimum wage, by categories	Level(s) <sup>a</sup>
<ul style="list-style-type: none"> <li>• First-time entrants to the labor market may receive less than the minimum wage rate. As of the end of 2005, remuneration for first-time entrants could not be less than 80% of the minimum wage for the first year and 90% for the second year of employment.</li> <li>• Other categories—For employees working on a part-time basis the amount of minimum wage is reduced proportionally to the actual number of hours worked.</li> </ul>	PPP\$448.86 per month.
	PPP\$224.02 per month.
<ul style="list-style-type: none"> <li>• States may establish regional minimum wage rates that are higher than the national minimum wage. Regional minimum wage rates are subject to the consent of the federal government.</li> </ul>	PPP\$59.47 per month.
	PPP\$818.16 per month.
<ul style="list-style-type: none"> <li>• If there is no collective agreement, the employer must pay a minimum wage according to the difficulty of the position, ranging from once to twice the minimum wage.</li> <li>• Juveniles between 16 and 18 years of age receive 75% of the minimum wage. Juveniles under 16 receive 50% of the minimum wage.</li> <li>• Employees with partial-disability pensions receive 75% of the minimum wage, while those with full-disability pensions and disabled persons under 18 receive 50% of the minimum wage.</li> </ul>	PPP\$376.01 per month.

(continued)

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
Turkey	Minimum wage rates are set by the Minimum Wage–Setting Board. The rate is supposed to be adjusted every two years. In practice, rates have been adjusted every 6 to 12 months.	The provisions of the Labor Act concerning the minimum wage apply to all employees.
<i>Africa</i>		
Angola	The minimum wage is set by decree of the Council of Ministers based upon the proposal made by the minister of protection, labor, and finance.	All workers are covered by minimum wage regulations. The government may exclude workers covered by a collective agreement signed within six months preceding the issue of the decree setting the minimum wage.
Botswana	Minimum wage rates are set by sector. The minister of labor must consult the Minimum Wage Advisory Board when adjusting or setting rates for trade or industry that may require a statutory minimum wage rate, but is not obliged to accept the board's recommendations. Additionally, the minister must publish a notice in the Official Gazette announcing the intention to alter rates before any adjustment is made. In practice, the rates are adjusted each year.	Minimum wage rates apply only to workers in the sectors set forth in the Employment Act, 1982. Unless the minister of labor issues a specific regulation, government officials are not covered by any minimum wage rate order.
Burkina Faso	The government determines one minimum wage rate for nonagricultural workers and one minimum wage rate for agricultural workers after receiving the opinion of the Labor Advisory Commission.	Minimum wage provisions apply to all workers except those employed in public administration and apprentices.
Cape Verde	There is currently no minimum wage in Cape Verde.	
Chad	The 1996 Labor Code provides for minimum wages to be determined in agreement with organizations representing employers and workers. In practice, minimum wage rates have not been adjusted since 1994.	The minimum wage applies to all workers.

Coverage: variations in minimum wage, by categories	Level(s) <sup>a</sup>
<ul style="list-style-type: none"> <li>There is a lower minimum wage rate for workers younger than 16 years of age. The minimum wage rate is currently TL378,000,000 per month (US\$251.85) for employees younger than 16.</li> </ul>	PPP\$590.93 per month for employees 16 years of age and above.
<ul style="list-style-type: none"> <li>The legislation provides that the minimum wage rates may be set by sector or by territorial region. However, as of 2003, only one national minimum wage rate had been established.</li> </ul>	US\$50 per month.
<ul style="list-style-type: none"> <li>The minister of labor sets minimum wage rates for night watchmen.</li> <li>The minister of labor may establish minimum wage rates for building and construction; exploration and quarrying industry; garage and motor trade; road transport industry; hotel, catering, and entertainment trade; manufacturing, service, and repair trade; and wholesale and retail distribution trade.</li> <li>Disabled persons to whom a wage order applies or their prospective employers may apply for a permit authorizing them to be paid less than the minimum wage rate.</li> </ul>	PPP\$0.86 per hour for night watchmen. PPP\$1.02 per hour for workers in trades set forth in the Employment Act other than the retail distribution trade.
<ul style="list-style-type: none"> <li>Piece-rate workers must receive wages that are proportional to those that would be received by a full-time worker.</li> </ul>	PPP\$0.89 per hour for agricultural workers. PPP\$0.97 per hour for nonagricultural workers.
<ul style="list-style-type: none"> <li>Minimum wage rates vary according to occupation and seniority.</li> <li>Separate minimum wage rates have been established for agricultural workers and nonagricultural workers.</li> <li>Workers between 14 and 18 years of age who are not working under a contract of apprenticeship may not receive less than 80% of the relevant minimum wage rate.</li> <li>The amount paid to a piece-rate worker must be proportional to what a worker paid per hour would receive for the same work.</li> </ul>	PPP\$171.45 per month for nonagricultural workers. PPP\$173.06 per month for agricultural workers.

(continued)

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
Gabon	The government sets a national minimum wage rate. It may also set minimum wage rates for certain professions if collective agreements do not provide minimum rates. The National Wage Committee must meet at least once every three years.	The minimum wage applies to all workers.
Ghana	The national daily minimum rate of remuneration is determined by the National Tripartite Committee.	Before the Labor Act of 2003, regulations did not apply to part-time workers, piece workers, sharecroppers, sea-going personnel who are not wage earners, and apprentices. In the absence of any revocation, these exemptions are assumed to apply.
Guinea-Bissau	The government sets the minimum wage rates by decree following consultation with social partners. This consultation takes place within the Social Dialogue Council (Conselho Permanente de Concertação Social), a tripartite advisory body. There are two national minimum wage rates: one for agricultural workers, and one for nonagricultural workers.	The minimum wages apply to all salaried workers, except domestic workers and public servants. Public servants are covered by a separate wage-setting system.
Lesotho	Minimum wage rates are set according to occupations in wages orders issued by the minister of labor on the basis of recommendations and proposals of the Wages Advisory Board. The Wages Advisory Board must examine the rates annually.	The minimum wage applies to all workers. Workers whose occupation is not specified in the wages orders must be paid at least the rate for unskilled laborers.
Madagascar	The government sets a national minimum wage rate and a wage scale for nonagricultural workers and agricultural workers based on recommendations of the National Employment Council.	The Labor Code applies to all workers whose employment contract was entered into in Madagascar.

## Annex 1: Characteristics of the Minimum Wage in Selected Countries

Coverage: Variations in minimum wage, by categories	Level(s) <sup>a</sup>
<ul style="list-style-type: none"> <li>Workers paid on a piece-rate basis must be paid at a rate that a worker of average capabilities working normally would be paid.</li> </ul>	PPP\$111.35 per month.
<ul style="list-style-type: none"> <li>The minister of labor may issue a permit excluding a person affected by some type of infirmity, physical injury, or disability from the legislative provisions concerning minimum wage.</li> </ul>	PPP\$7.69 per day.
<ul style="list-style-type: none"> <li>The law provides that different national minimum wages can be set by sector.</li> <li>An employee under the age of 16 shall be paid no less than 60% of the national minimum rate. An employee between the age of 16 and 18 shall be paid a rate not less than 80% of the national minimum rate. A minor with more than six months of employment in the same activity shall be paid the full minimum rate.</li> </ul>	PPP\$25.00, plus one bag of rice per month.
<ul style="list-style-type: none"> <li>Minimum wage rates have been established for the following occupations: drivers; hammer mill operators; junior clerks; machine operators; machine attendants; messengers; receptionists; shop assistants; telephone operators; ungraded artisans; unskilled laborers; waiters; trainee weavers and sewing machine workers; watchmen; domestic workers; and copy-typists.</li> <li>Workers employed by small businesses whose occupation is not specified in a wages order must be paid at least the minimum wage rate for small businesses, which is lower than the rate for unskilled laborers.</li> <li>Wage rates are set on a wage scale that allows for rates to vary in accordance with level of seniority and professional category.</li> <li>Rates paid to piece workers must be such that an average worker working at a normal rate receives the same wage as workers being paid according to the time worked.</li> </ul>	PPP\$105 per month for domestic workers. PPP\$210.5 per month for workers in small businesses. PPP\$310.50 per month for unskilled laborers. PPP\$595.50 per month for drivers. PPP\$70.4 per month for nonagricultural workers. PPP\$80.63 per month for agricultural workers.

(continued)

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
Mauritius	There is no national minimum wage. The minister of labor sets minimum wage rates for workers in the private sector in industry-wide remuneration orders on the basis of recommendations from the National Remuneration Board; he may accept, reject, or amend the recommendation. The Pay Research Bureau establishes wages for public sector workers. Each year, on July 1, the wages of private sector workers are adjusted for increases in the cost of living.	Minimum wages have been established for 29 industries and occupations in the private sector. Workers in other industries or occupations have no statutory minimum wage rate.
Mozambique	Minimum wage rates are set by consensus by the Labor Advisory Commission with the participation of social partners. Agreements are announced by the government. If no agreement proves possible, the government sets the minimum wage rates.	A minimum wage rate is determined for agricultural workers, and another for workers in industry, trade, and other activities.
Namibia	There is no national minimum wage. Minimum wage rates may either be set by the government in wage orders or in collective agreements. All minimum wage rates are currently set in collective agreements. Adjustments to the rate in the agricultural sector should be discussed on an annual basis.	Minimum wage rates apply to agricultural workers in a collective agreement and workers in the mining and construction sectors.
Nigeria	A national minimum wage is determined by the government. In 2000, when the national minimum wage rate was updated, an ad hoc tripartite committee was formed to facilitate discussions on the new rate.	National minimum wage rates do not apply to: establishments employing fewer than 50 workers, part-time workers, workers paid on a commission or piece-rate basis, workers in seasonal employment such as agriculture, and workers in merchant shipping or civil aviation.
São Tomé and Príncipe	The government sets the minimum wage rate.	The minimum wage rate applies to all workers. However, the legislation does allow different sectoral minimum wages.

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
Senegal	There are national minimum wage rates for nonagricultural workers and agricultural workers. In addition, minimum wage rates higher than these rates can be set by joint committees for sectors covered by collective agreements.	The minimum wage rates for agricultural and nonagricultural workers apply to all workers.
South Africa	A dual system of minimum wage–setting has been established. The government may set rates for certain sectors in sectoral determinations, following recommendations of the Employment Conditions Commission. In addition, minimum wage rates may be determined in collective agreements. Most of the sectoral determinations predetermine increases (or link them to the consumer price index) for the subsequent three years.	The Basic Conditions of Employment Act applies to all employees and employers, except members of the National Defense Force, the National Intelligence Agency, and the Secret Service, unpaid volunteers working for charitable organizations, and persons employed on sea vessels. Sectoral determinations may not apply to workers already bound by collective agreements.
<i>East Asia and the Pacific</i>		
Cambodia	The Ministry of Labor sets a guaranteed minimum wage based on recommendations made by the Labor Advisory Committee.	The Labor Code applies to all professional, charitable, and educational enterprises. It does not apply to judges; permanent public servants; members of the police, army, military forces, air and maritime transportation personnel (governed by a separate statute); and domestic workers.
China	The government is responsible for implementing a system of regional minimum wage rates; there is no national minimum wage rate. Standards are stipulated by provincial, regional, and municipal governments and reported to the State Council for consent. They are adjusted at least once every two years.	The provisions concerning minimum wages apply to enterprises, private nonenterprise entities, individual industrial and commercial households, and the laborers who have formed a labor relationship with them.

Coverage: variations in minimum wage, by categories	Level(s) <sup>a</sup>
<ul style="list-style-type: none"> <li>Workers paid by the piece and working for at least two weeks must receive at least 90% of the applicable minimum wage.</li> </ul>	PPP\$0.82 per hour for agricultural workers. PPP\$0.94 per hour for nonagricultural workers.
<ul style="list-style-type: none"> <li>Sectoral determinations have been established for domestic workers, contract cleaning workers, private security workers, farm workers, wholesale and retail workers, welfare workers, and engineers.</li> <li>Minimum wage rates vary by region.</li> <li>In the wholesale and retail sector, a specific minimum wage rate is stipulated for trainee managers and trainees. Also, employees who perform commission work must receive at least two-thirds of the applicable minimum wage.</li> </ul>	PPP\$280.39 per month for farm workers. PPP\$514.31 per month for general assistants in the wholesale and retail sector.
<ul style="list-style-type: none"> <li>As of October 2003, minimum wage rates had only been set for the textile, garment, and shoe manufacturing industries.</li> <li>Minimum wage rates may vary regionally.</li> <li>Workers on a probation period (one to three months) may receive a minimum wage slightly lower than the regular rate.</li> <li>Piece-rate workers must be paid by the hour at least the amount guaranteed to a worker earning the minimum wage.</li> </ul>	US\$45 per month for regular workers in the textile, garment, and footwear sector.
<ul style="list-style-type: none"> <li>Different minimum wage rates may be set in each province and within the separate administrative areas of each province. All of China's 39 provinces, regions, and municipalities are subject to minimum wage legislation.</li> </ul>	PPP\$104.80 per month in certain towns in Jiangzxi region. PPP\$350.21 per month in Shanghai city.

(continued)

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
Fiji	There is no national minimum wage in Fiji. The government may establish Wages Councils for groups of workers if no collective bargaining mechanism is in place. Wages Councils make wage regulation proposals to the minister of labor who may enact the proposal as an order. Minimum wages for sectors of the workforce not covered by Wages Councils are determined in collective agreements.	Only workers in sectors covered by Wages Councils are entitled to statutory minimum wage rates.
Indonesia	The governor of each province sets minimum wage rates for the respective province or regency. The Law on Manpower Affairs provided that a National Wage Council, Provincial Wage Councils, and District/City Wage Councils should be established to develop a national wage system. Minimum wages are reviewed by each province on a yearly basis.	All workers are covered by minimum wage regulations except for domestic workers. The legislation provides for exceptions for companies unable to pay minimum wage rates.
Korea, Republic of	The minister of labor sets the national minimum wage each year, following the Minimum Wage Council's proposal. If the minister of labor does not agree with the wage proposal, but two-thirds of the Council support it, the minister must adopt the proposal. The minister of labor publishes the rate proposals, and representatives of workers or employers may raise objections within 10 days of publication.	The minimum wage applies to all workers, except domestic workers and businesses using only relatives living together. An employer may obtain permission to exclude certain workers from minimum wage provisions in cases of disability, probation (a maximum of three months), training, or for workers engaged in surveillance or intermittent work.
Lao PDR	The Labor Act of 1994 states that the government or other relevant body will establish minimum wage rates for each region.	The Labor Act applies only to workers in the formal sector. The Act does not apply to civil servants employed in state administrative and technical services, national defense, or public order.

Coverage: variations in minimum wage, by categories	Level(s) <sup>a</sup>
<ul style="list-style-type: none"> <li>• Rates are set for the building, civil, and engineering trade; wholesale and retail trade; hotel and catering trade; road transport; mining and quarrying industries; saw milling and logging industry; printing trades; garment industry; and manufacturing industry.</li> <li>• All apprentices are entitled to minimum hourly rates in accordance with the number of years of apprenticeship completed.</li> <li>• A few industries have set separate rates for workers under 18.</li> <li>• A disabled worker, employer, or prospective employer may apply for a reduced minimum wage rate to apply to the worker.</li> <li>• The minimum wage is increased by 25% for casual workers.</li> </ul>	<p>PPP\$1.31 per hour for learners in the garment industry.  PPP\$2.16 per hour for workers in printing trades.</p>
<ul style="list-style-type: none"> <li>• Many provinces have set a basic minimum wage that applies to all sectors. However, provinces are entitled to set separate minimum wages for each sector on the basis of agreements between corporate organizations and worker unions or labor federations.</li> <li>• Workers on probation must be paid the minimum wage.</li> <li>• Piece-rate workers, contractors, and freelancing daily workers are covered if they are employed for one month or more.</li> </ul>	<p>PPP\$113.88 per month in East Java.  PPP\$255.06 per month in the province of Jakarta.</p>
<ul style="list-style-type: none"> <li>• Separate minimum wage rates may be set for seamen.</li> <li>• Workers under the age of 18 employed for less than six months should receive 90% of the applicable minimum wage rate.</li> <li>• Workers with a disability may be excluded from minimum wage protection.</li> <li>• Piece-rate workers must receive hourly wage rates equivalent to the minimum wage rate. The Minimum Wage Act stipulates that a separate minimum wage rate may be determined for piece workers. No decrees in this regard have yet been made.</li> <li>• The legislation also applies to contractors, for whom the minimum wage rate shall be determined according to a certain unit of output or achievement.</li> </ul>	<p>PPP\$674.74 per month.</p>
<ul style="list-style-type: none"> <li>• Workers on a probationary period must receive at least 90% of the applicable minimum wage (for a maximum of one or two months).</li> <li>• Workers may only be paid on a piece-rate basis if the government or relevant body has not established a minimum wage rate for a specific region, or if the employer allows workers to bring and do supplementary work outside their labor unit.</li> </ul>	<p>PPP\$46.19 per month.</p>

(continued)

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
Malaysia	There is no national minimum wage. The government may establish Wages Councils for certain nonunionized sectors of the workforce not covered by collective agreements. These councils submit wage regulations proposals, which the government may choose to enact in a wage regulation order.	Wages Councils have been established for certain nonunionized sectors of the workforce not covered by collective agreements. Casual workers or someone employed other than for the purposes of the employer's business are excluded from minimum wage protection.
Papua New Guinea	A Minimum Wages Board may make determinations on minimum wages, which must be approved by the head of state. Currently, one national minimum wage rate has been established. Minimum wages may also be set in registered awards and common rules. A 1992 determination states that future determinations should be made following negotiations between employers and employees, which has not happened to date.	The minimum wage applies to all employees and employers.
Philippines	Regional Tripartite Wages and Productivity Boards determine minimum wage rates applicable in their regions, provinces, or industries subject to the guidelines set by the National Wages and Productivity Commission. In addition, the secretary of labor and employment may establish the minimum wage rate for home workers and those employed in cottage industries. Wage orders should be determined whenever conditions in the region so warrant, but no sooner than 12 months after issuance of rates by the boards, unless particular circumstances warrant it.	The provisions do not apply to domestic workers, home workers carrying out needlework, or workers in cottage industries. A minimum wage rate for domestic workers is provided separately. Retail or service establishments with fewer than 10 workers may apply to be excluded from the requirements.
Solomon Islands	The minister of labor may set minimum wage rates. The minimum wage may be abated by way of a collective agreement if the commissioner for labor provides a written permit for such abatement.	The minimum wage provisions apply to all workers except domestic workers and seamen.

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
Thailand	The National Wage Committee makes a recommendation concerning adjustments to the basic minimum wage rate. In addition, tripartite provincial committees can recommend a minimum wage higher than the basic rate for certain provinces. The National Wage Committee must report to the labor minister at least once a year.	The Labor Protection Act does not apply to central, provincial, and local administration and state enterprises governed by the Law on State Enterprises, or to agricultural workers, domestic workers, or employers who run private schools.
Vietnam	The Ministry of Labor, War Invalids, and Social Affairs may set minimum wage rates that vary across regions and for local or foreign firms. The legislation does not set specific time periods for adjustment.	The Labor Code applies to all workers.
<i>Latin America and the Caribbean</i>		
Argentina	The National Council for Employment, Productivity, and the Adjustable Minimum Living Wage periodically determines the adjustable minimum wage. The government did not convene the council in setting the minimum wage for January 2004, since the economic crisis and the need for an urgent rise in wages constituted exceptional circumstances, but set the wage by presidential decree. The minimum wage can be adjusted at any time at the request of any social partner.	The minimum wage applies to both private and public sector workers.
Bahamas	Statutory minimum wage rates are set by the government. Separate rates are established for workers employed by the week, the day, or the hour. Prior to any increase in the minimum wage rates, consultation must take place with representatives of employers and an association of registered trade unions.	Minimum wages apply to all employees in the private and public sectors. The Minister of Labor may exclude certain persons or sectors. Children and young persons (no definition provided) are excluded from minimum wage protection.

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
Belize	Minimum wage rates are set by the Minister of Labor for workers covered by a Wages Council. These councils were established in response to a lack of effective wage regulation by collective agreement for the workers concerned. Wages Councils submit wage proposals to the minister, who may make a wages regulation order for the workers concerned.	Only workers covered by a wages regulation order are covered. Casual workers are excluded.
Bolivia	The Ministry of Labor sets the minimum wage for different regions and categories of workers. In practice, the president, together with the Council of Ministers, sets the minimum wage by supreme decree.	The minimum wage applies to all workers in the public and private sectors. There is one general minimum wage rate for all employees except agricultural workers.
Brazil	The national minimum wage rate is set by law. Currently, the minimum wage is set by a provisional measure in accordance with the Federal Constitution and placed before Congress for conversion into law. The legislation establishes that minimum wage adjustments should take place every three years; however, in reality, the rate has been set annually.	
Chile	The government sets two minimum wage rates by law: one for workers between 18 and 65 years old, and one for workers under 18 and over 65. A rate for “nonremunerative” purposes is also set and used solely as a reference point for calculating fines, taxes, fees, and so on. It does not establish the actual minimum wage to be paid to workers.	Minimum wage legislation applies to workers in the private sector. Remuneration for apprentices and mentally disabled workers is freely agreed by parties and is not subject to minimum wage legislation.
Colombia	The minimum wage is set by the Permanent Commission on the Harmonization of Wage and Labor Policies through an executive decree. If the commission cannot reach consensus, the government sets the minimum wage. The commission is a tripartite institution made up of government, worker, and employer representatives. The minimum wage is adjusted once a year.	All workers in the private sector are covered by minimum wage legislation.

## Annex 1: Characteristics of the Minimum Wage in Selected Countries

Coverage: variations in minimum wage, by categories	Level(s) <sup>a</sup>
<ul style="list-style-type: none"> <li>Minimum wages have been established for manual workers, shop assistants, and domestic helpers.</li> <li>Workers that are infirm or incapacitated may apply for an exception from a wage regulation order.</li> <li>Students employed as shop assistants are entitled to a lower minimum wage rate than regular workers.</li> </ul>	<p>PPP\$2 per hour for students employed as shop assistants and manual workers engaged in agriculture, agroindustry, or export-oriented industries.</p> <p>PPP\$2.25 per hour for other workers.</p> <p>PPP\$163.71 (assumed to be per month).</p>
<ul style="list-style-type: none"> <li>For piece-rate workers, the wage is set to ensure that it is no lower than the normal daily minimum wage.</li> </ul>	<p>PPP\$235.41 per month.</p>
<ul style="list-style-type: none"> <li>There is a specific minimum wage rate for workers under 18 or over 65.</li> <li>The minimum remuneration for domestic workers cannot be less than 75% of the monthly minimum.</li> </ul>	<p>PPP\$385.84 per month for workers aged 18 to 65.</p>
<ul style="list-style-type: none"> <li>Part-time workers receive a pro rata minimum wage according to the hours effectively worked.</li> </ul>	<p>PPP\$483.15 per month.</p>

(continued)

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
Costa Rica	The National Wage Council sets minimum wages by sector and occupation for workers in the private sector through executive decrees. The council’s proposal for adjustments is sent every year to the Ministry of Labor for comment, and the final decision is made by the council. In addition, minimum wages can be revised at any time during the year at the request of 5 employers or 15 workers.	General rates tend to apply to workers in occupations requiring a professional qualification and vary according to qualification. Sectoral rates are set for nonqualified, partially qualified, and specialist workers. Occupational rates are defined by the National Wage Council in its “Occupational Profiles.”
Cuba	Minimum wages are set by the Council of Ministers in consultation with the central union of workers.	All workers are covered by minimum wage legislation.
Dominican Republic	Minimum wages for private sector workers are set by occupation and sector by the National Salary Committee, which adjusts minimum wages at least every two years. In principle, the minimum wages cannot be changed within the first year of validity. However, if the employers or the workers prove that a certain minimum wage rate impairs one of the social partners and causes detriment to the national economy, the committee may adjust the rate. The minimum wage for public sector workers is set directly by executive decree.	Minimum wages are set by occupation and sector.
Ecuador	The government, through the National Wage Council, sets minimum wages for workers in the private sector and the general “vital” minimum wage rate, which is used as a reference point for calculating fines, taxes, fees, and so on. The National Wage Council is a tripartite institution made up of three representatives: one each from government, employers, and workers. In case the National Wage Council cannot reach a consensus, the Ministry of Labor sets the minimum wage rates. Minimum wages are updated yearly.	Minimum wage rates apply to all workers in the private sector and are set by sector and occupation.

## Annex 1: Characteristics of the Minimum Wage in Selected Countries

Coverage: variations in minimum wage, by categories	Level(s) <sup>a</sup>
<ul style="list-style-type: none"> <li>• Rates vary by sector and occupation.</li> <li>• Minimum wage rates for youth are no less than 50% of the relevant minimum wage rate during the first year of employment and no less than 75% during the second year.</li> <li>• Workers carrying out dangerous or unhealthy work are entitled to an hourly minimum wage equivalent to one-sixth of the daily minimum wage for nonqualified workers set by sector.</li> <li>• Piece-rate workers cannot be paid less than what a worker would have received if working an ordinary working day.</li> </ul>	<p>PPP\$345.35 per month for domestic workers. PPP\$19.92 per day for nonqualified workers in the agricultural, fishing, forestry, and mining industries, or the electricity, commerce, tourism, services, transport, and warehousing sectors.</p>
<ul style="list-style-type: none"> <li>• Minimum wage rates vary by sector and by occupation. They are set for laborers, administrative and service workers, technicians, and managers.</li> <li>• The minimum wage for part-time workers is proportional to the time worked.</li> <li>• A minimum wage rate is set for the agricultural sector.</li> </ul>	<p>PPP\$7.40 per day for workers in the sugar industry. PPP\$587.38 per month for workers in large industrial, commercial, or service companies.</p>
<ul style="list-style-type: none"> <li>• Minimum wages are set for workers operating heavy machinery, electricians, painters, carpenters, and plumbers.</li> <li>• Minimum wages are set for agriculture; hotels, restaurants, bars, cafes and other food service establishments; the construction industry; the sugar industry; and sectors that do not have a specific rate. In certain sectors, minimum wage rates depend on the size of a company and the nature of the business.</li> <li>• Minimum wage rates are set in accordance with production for the following occupations: carpenters, electricians, plumbers, painters, bricklayers, and heavy-machine operators in agriculture.</li> <li>• Minimum wages for part-time workers shall be calculated on a pro rata basis.</li> <li>• The remuneration for apprentices cannot be less than the minimum wage and should be calculated according to the hours of training.</li> </ul>	<p>PPP\$90.79 per month for domestic workers. PPP\$256.11 per month for workers in the small-scale industry sector, agricultural sector, and other general workers.</p>

(continued)

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
El Salvador	Minimum wage rates are set by the government for certain sectors following proposals of the National Minimum Wage Council. The executive has the discretion to accept the proposals and set the rates by decree or direct the council to reconsider. The wages are adjusted at least every three years.	Minimum wage rates apply to selected sectors.
Guatemala	Minimum wage rates for private sector workers are set as follows. Joint minimum wage boards in each region and economic zone make recommendations to the National Wage Commission, a technical and advisory body attached to the Ministry of Labor and Social Welfare. The commission issues a report harmonizing all the proposed rates. Finally, the executive sets the rates (which apply nationwide with no regional variation) with the Ministry of Labor and Social Welfare. Rates are adjusted every year.	Minimum wage rates are set by sector and occupation, and rates apply to all workers except those employed by the state.
Haiti	The minimum wage is set by the government. In 1995, the Committee for Consultation and Arbitration was established to make recommendations concerning the minimum wage. The minimum wage is supposed to be adjusted for changes in the cost of living and must be increased when the annual inflation rate is more than 10%.	The national statutory minimum wage applies to all workers in commercial, industrial, and agricultural establishments. Domestic workers are not covered.
Honduras	The National Minimum Wage Commission sets minimum wages by sector. This tripartite institution comprises government, employer, and employee representatives. If it does not reach a consensus, the executive has the authority to increase the minimum wage. Minimum wages are adjusted each year. At the request of employers or workers, they can also be revised every six months if inflation is more than 12%.	All workers in the private sector are covered by minimum wage legislation except for apprentices. Minimum wages vary according to sector, the type of business concerned, and the number of employees.

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
Mexico	Minimum wage rates are set by the National Commission on Minimum Wages, a tripartite institution made up of representatives of the government, employers, and workers. Special boards may be appointed to provide advice to the commission. Minimum wages are adjusted each year and can be revised at any time if economic circumstances so warrant.	There are two types of minimum wage: the general minimum wages that apply to all workers and occupational minimum wages (higher than the general minimum wages). Both wages vary by geographic area. The legislation applies to private sector workers.
Nicaragua	Minimum wages are set by the National Minimum Wage Commission, which comprises representatives of the Ministries of Labor and of the Economy and Development, major national employer associations, and trade unions. The wages are supposed to be adjusted every six months.	Workers in both the private and public sector are covered by minimum wage legislation. There is no general minimum wage rate, but, rather, minimum wage rates that vary by sector.
Panama	Minimum wages are set by executive decree following recommendations of the National Minimum Wage Commission, a tripartite institution comprising worker, employer, and government representatives. Minimum wages are supposed to be adjusted at least every two years.	The legislation covers only workers in the private sector. There is no general minimum wage rate. Minimum wage rates vary according to regions, sectors, and company size. A worker providing services in more than one area receives the most favorable rate.
Paraguay	Minimum wages are set by the government according to proposals of the National Minimum Wage Council, a tripartite institution made up of government, employer, and worker representatives. The rates are supposed to be updated every two years. The government may change the rates earlier if there is a significant alteration in the conditions of a sector or industry or if there is a variation of at least 10% in the cost of living.	Minimum wage legislation applies to all workers in the private sector. Minimum wages are set by occupation and by sector. There is also a minimum wage rate applicable to those occupations and sectors that do not have a specific minimum wage rate.

## Annex 1: Characteristics of the Minimum Wage in Selected Countries

Coverage: variations in minimum wage, by categories	Level(s) <sup>a</sup>
<ul style="list-style-type: none"> <li>There are 88 occupational minimum wages set for occupations such as bricklayers, archive workers, drugstore salespersons, cashiers, bartenders, carpenters, brush operators, chefs, mattress producers, accountants, shoemakers, tailors, car drivers, bus drivers, truck drivers, furniture restorers, electricians, supermarket workers, nurses, gas station workers, locksmiths, and jewelers.</li> </ul>	PPP\$5.83 per day for area C. PPP\$6.27 per day for area A.
<ul style="list-style-type: none"> <li>Rates have been established for the following sectors: agriculture; fishing; mining; manufacturing; some industries; electricity, gas, and water; construction; commerce, the restaurant and hotel industry; transport, warehousing, communication; financial and insurance services; and central and local government.</li> <li>Minimum wages for prison workers cannot be lower than the regular applicable minimum wage.</li> </ul>	PPP\$129.50 per month for agricultural workers. PPP\$304.77 per month for construction workers.
<ul style="list-style-type: none"> <li>Rates are set for domestic workers, wood producers, furniture and mattress producers, food producers, personal services providers, and air and water transportation workers.</li> <li>Rates are set for agriculture, forestry, hunting, fishing, the manufacturing sector, electricity, gas, water, construction, large- and small-scale commerce, hotels, restaurants, transport, warehousing, telecommunications, financial intermediaries, real estate, and social and personal services.</li> </ul>	PPP\$1.84 per hour for agricultural workers in small-scale companies.
<ul style="list-style-type: none"> <li>Apprentice remuneration may not be less than 60% of the minimum wage.</li> <li>The remuneration of minors may not be less than 60% of the minimum wage and a progressive scale based on years effectively worked. A minor performing the same work as an adult must be paid the full minimum wage.</li> <li>Remuneration for physically and mentally disabled persons can be lower than the minimum wage.</li> <li>The daily minimum wage for piece-rate workers shall not be lower than the monthly minimum wage divided by 26.</li> </ul>	The minimum wage rate applicable to those occupations and sectors that do not have specific minimum wage rates is PPP\$694.03 per month.

(continued)

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
Peru	The minimum wage is set by the National Labor and Employment Promotion Council, a tripartite institution made up of government, worker, and employer representatives. If there is no agreement on a minimum wage rate within the council, the president sets the minimum wage through emergency decree.	All workers in the private sector are covered by minimum wage legislation. There is one general minimum wage rate applicable to all workers in the private sector.
Trinidad and Tobago	The government sets the minimum wage in an order based on the recommendation of the Minimum Wages Board.	The order does not apply to trainees in government-approved training schools, registered apprentices, workers in certain government-approved schemes, students on vacation jobs, and volunteers in registered charities.
Uruguay	The government sets the national minimum wage by decree.	The national minimum wage applies to the public and private sectors. There are three minimum wage rates: general, for rural workers, and for domestic workers.
Venezuela	The Ministry of Labor sets minimum wages based on recommendations by the Tripartite Commission for the Revision of the Minimum Wage. In the absence of a recommendation, the executive may unilaterally set the rates. In case of large increases in the cost of living, the executive may set rates by decree, taking into account comments of worker and employer representatives, the National Economic Council, and the Central Bank. Rates are adjusted yearly.	Minimum wages apply to both private and public sector workers. There is no general minimum wage rate. There are different minimum wage rates for: urban workers, workers in companies with fewer than 20 workers, rural workers, and youth and apprentices.
<i>Middle East and North Africa</i>		
Algeria	In accordance with the law on labor relations, the government sets a national minimum wage following consultation with social partners.	All workers, except national defense personnel, magistrates, state officials, and personnel of selected public establishments. Legislation may be enacted for managers, journalists, pilots, captains, seafarers, home workers, artists, commercial representatives, athletes, and domestic workers.

## Annex 1: Characteristics of the Minimum Wage in Selected Countries

Coverage: variations in minimum wage, by categories	Level(s) <sup>a</sup>
<ul style="list-style-type: none"> <li>Remuneration for youth, trainees, and apprentices cannot be lower than the minimum wage. If they work less than a full working day, the remuneration should be set on a pro rata basis.</li> </ul>	PPP\$309.94 per month.
<ul style="list-style-type: none"> <li>Piece-rate workers and offsite workers must be paid an agreed piece-rate or an hourly rate based on a fair estimate of the equivalent number of hours and on the minimum wage.</li> </ul>	PPP\$282.62 per month.
<ul style="list-style-type: none"> <li>Minimum wage rates for domestic workers vary by region.</li> <li>Minimum wage rates for agricultural laborers vary by occupation.</li> </ul>	PPP\$110.19 per month.
<ul style="list-style-type: none"> <li>The minimum wage rate applicable to workers in companies with fewer than 20 workers is also applicable to domestic workers.</li> <li>If apprentices and youth render services under the same conditions as urban or rural workers, the regular minimum wage rates apply.</li> </ul>	PPP\$265.84 per month for rural workers. PPP\$295.37 per month for urban workers.
<ul style="list-style-type: none"> <li>Apprentices receive a presalary equivalent to 15% of the national rate for six months (if the apprenticeship stays less than 24 months) or for 12 months (if the apprenticeship stays more than 24 months).</li> <li>Wages for home workers may not be lower than the national minimum wage rate.</li> </ul>	PPP\$389.41 per month.

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
Lebanon	The national minimum wage rate is set by the government in accordance with a report of the tripartite Commission on the Cost of Living Index, comprising representatives of the government, employers, wage earners, and salaried earners.	The minimum wage applies to all workers over 20 years of age in the public and private sector except for domestic servants, workers in agricultural corporations not connected to trade and industry, workers in family businesses, and temporary workers in public administration.
Morocco	National minimum wage rates are set by the government following consultation with the most representative employee and employer organizations.	Rates are set for agricultural workers, industrial and commercial workers, and the liberal professions. Certain categories of employers may be excluded from the legislation following consultation with employee and employer organizations.
Tunisia	Minimum wage rates are set and revised by the government in a decree following consultations with worker and employer organizations. In practice, the National Committee on Social Dialogue is consulted. The legislation does not set forth how frequently rates should be adjusted, but, in practice, they are updated each year.	Rates are set for agricultural workers and other workers. The Labor Code applies to all public and private employers, including cottage industries, cooperatives, professionals, unions, and other organizations. It excludes domestic workers.
<i>South Asia</i> Bangladesh	The Minimum Wages Board may recommend the minimum wage rates for workers in industries. The Council of Minimum Wages and Prices for Agricultural Labor may recommend the minimum wage rate for agricultural laborers (the council has not yet been established). The Export Processing Zones Authority establishes separate minimum wage rate for companies within export processing zones. The Minimum Wages Board should review any recommendations at least once during any three-year period.	Minimum wage rates have been established for workers in the garment industry, export processing zones, and agriculture. Persons employed by federal or provincial governments are excluded from minimum wage rates set in wage board ordinances for workers in industries.

## Annex 1: Characteristics of the Minimum Wage in Selected Countries

Coverage: variations in minimum wage, by categories	Level(s) <sup>a</sup>
	PPP\$239.00 per month.
<ul style="list-style-type: none"> <li>• Apprentices may be paid wages lower than the minimum rates.</li> <li>• Employees paid by the piece, output, or production must receive a salary equivalent to the minimum rate unless output is reduced as a result of factors within the control of the employee concerned.</li> <li>• Employees whose salaries are made up entirely of tips or tips and a base salary are entitled to receive at least the minimum wage rate. If the tips are not sufficient, the employer must pay the difference.</li> </ul>	PPP\$14.18 per day for agricultural workers.
<ul style="list-style-type: none"> <li>• A minimum wage rate is set for workers under 18 years of age; this is currently at 85% of the relevant adult rate.</li> <li>• Wage rates for workers paid per piece produced must be set at the equivalent of the minimum wage rate.</li> </ul>	PPP\$14.58 per day for agricultural workers. PPP\$411.97 per week for nonagricultural workers.
<ul style="list-style-type: none"> <li>• Apprentices have a slightly lower minimum wage rate than regular workers in export processing zones. Separate wage rates are also set for trainees or apprentices in the garment industry.</li> </ul>	PPP\$49.23 per month for helpers in the garment industry. PPP\$73.84 per month for machine operators in the garment industry. PPP\$148.91 per month for helpers in export processing zones. PPP\$248.18 per month for ordinary operators in electronics industries in export processing zones.

**TABLE 3A.1. Characteristics of the Minimum Wage in Selected Countries (Continued)**

<i>Country</i>	<i>Minimum wage–setting procedure</i>	<i>Coverage: scope</i>
India	Minimum wage rates for occupations that are largely nonunionized or have little bargaining power may be set in accordance with the Minimum Wages Act, 1948. Both central and local governments may set minimum wage rates for nonunionized occupations. Reviews of the rates should take place at least every five years.	The law applies throughout India except in Sikkim. The central government sets rates for 45 different occupations, while states have set rates for 1,232 occupations in their jurisdictions. The law does not apply to organized occupations or to family members employing other members who live with and depend on them.
Nepal	The government sets minimum wage rates on the basis of recommendations by the Minimum Remuneration Fixation Committee (nonagriculture) and the High Level Monitoring Committee (agriculture). In the absence of recommendations, the government may prescribe the rates.	Minimum wage rates are set for all agricultural workers and for nonagricultural workers in enterprises with more than 10 workers (for unskilled, semiskilled, skilled, and highly skilled workers). Domestic workers are excluded from the provisions.
Pakistan	The government sets a minimum wage rate. Provincial minimum wage boards may recommend minimum wage rates that the provincial governments should adopt for unskilled and juvenile workers (not done in practice) and for skilled workers in industries without effective collective bargaining mechanisms (done in a few regions). The minimum wages boards should review recommendations not less than every three years.	The legislation applies to all unskilled workers in commercial and industrial establishments (all sectors). It does not apply to workers in agriculture, federal or provincial governments, coal mines, public utilities, defense, or public services.
Sri Lanka	Minimum wage rates are set by wage boards for 39 trades and by the Remuneration Tribunal for shop and office employees. The legislation does not provide specific dates when minimum wage rates should be adjusted.	Any person working in a trade for which no wages boards or remuneration committees have been established is excluded from the national system of minimum wage. The legislation makes no provision for domestic workers or for workers in the fishing sector.

## Annex 1: Characteristics of the Minimum Wage in Selected Countries

Coverage: variations in minimum wage, by categories	Level(s) <sup>a</sup>
<ul style="list-style-type: none"> <li>The regional minimum wage rates should not be less than the minimum floor wage set by the minister of labor.</li> <li>Specific minimum wage rates may be established for apprentices, adolescents (14 to 18 years of age), and children under 14.</li> <li>The appropriate government may exclude disabled employees from certain provisions of the legislation.</li> </ul>	<p>PPP\$5.85 per day for unskilled construction workers in most rural areas.</p> <p>PPP\$10.43 per day for unskilled agricultural workers in some areas.</p>
<ul style="list-style-type: none"> <li>A lower rate is set for workers between 14 and 16 years of age.</li> </ul>	<p>PPP\$133.94 per month for unskilled workers on tea estates.</p> <p>PPP\$197.3 per month for workers and employees not working on tea estates.</p>
<ul style="list-style-type: none"> <li>Apprentices are excluded from the legislation, but the apprenticeship rules provide that apprentices receive a guaranteed rate that starts at 50% of the regular rate in the first year and increases up to the regular rate after three years.</li> </ul>	<p>PPP\$182.08 per month.</p>
<ul style="list-style-type: none"> <li>Minimum wage rates may vary in accordance with a worker's skill level.</li> <li>Lower minimum wage rates than those set for adults have been established for apprentices, trainees, and learners in selected trades.</li> <li>Many wage boards set lower minimum wage rates for children.</li> <li>Disabled workers may be granted reduced minimum rates.</li> <li>Wage boards may determine minimum wage rates for piece work.</li> </ul>	<p>PPP\$3.85 per day for rubber workers.</p> <p>PPP\$50.70 per month for preschool assistants.</p> <p>PPP\$128.98 per month for textile workers.</p>

## Slovenia: The growth effects of structural reform

<b>SLOVENIA: THE GROWTH EFFECTS OF STRUCTURAL REFORM.....</b>	<b>1</b>
<b>KEY FINDINGS .....</b>	<b>2</b>
<b>QUANTIFYING THE EFFECTS OF THE REFORMS: DETAILS AND ANALYSES .....</b>	<b>3</b>
<b>ANNEX: REFORMS TAKEN INTO ACCOUNT IN THE QUANTIFICATION EXERCISE .....</b>	<b>6</b>
<b>REFERENCES .....</b>	<b>8</b>

## Key findings

To improve Slovenia's long-term growth prospects and support job creation, comprehensive structural reforms are needed to boost competitiveness, in particular by addressing the country's productivity gap with other OECD countries. Slovenia has implemented many reforms in recent years, including of the pension system and labour and product markets. Other reforms such as the restructuring and recapitalisation of banks, the initiation of privatisations, and changes to the fiscal framework have been legislated and are ongoing, and their full implementation will support growth further going forward.

Drawing on the 2015 OECD Economic Survey of Slovenia, this paper provides a snapshot at the pension, product markets, and labour market reforms that have been implemented or approved and assesses their impact on productivity, employment and GDP. After five years, GDP will be 1% higher than would otherwise be the case in the absence of the reforms. This means that GDP will grow 0.2% faster per year on average over this period thanks to the reforms. In the following five years a further gain of similar magnitude can be expected. These estimates assume swift and full implementation of the reforms - delays, or less than full implementation, would reduce the gains.

- The *product market reforms* are estimated to boost GDP by around 0.7% after five years and 1.3% after ten years. This is driven by higher productivity growth as lighter regulation due to simpler rules on opening a business, reduced administrative burdens, and lower state-control encourage competition. This in turn speeds up the pace of convergence in productivity levels to the most technologically advanced economies. Lighter regulation also encourages firms to produce new ideas and technologies and facilitates the shift of resources from slow- to fast-growing sectors.
- The 2013 *labour market reform* is expected to boost GDP by 0.2% after five years and 0.3% after ten years. The positive GDP effect comes through higher productivity growth via increased flexibility of the labour market. Next to enhanced flexibility, the labour market reform also reduced duality between permanent and fixed-term contracts. This is a positive step, since labour market duality reduces firms' ability to adapt to shocks and unfairly distributes the burden of workforce adjustments towards vulnerable groups.
- The 2013 *pension reform* is expected to boost GDP by 0.1% after five years and 0.4% after ten years. The positive GDP effect comes through higher employment via increased incentives for older people to stay in the labour market. By increasing the statutory and minimum retirement ages and reducing the implicit tax on continued work for older people, the reform also made the pension system more sustainable.

## Quantifying the effects of the reforms: details and analyses

The Slovenian government has implemented a number of important structural reforms in recent years to boost growth. This paper provides an estimate of the impact of the product and labour market reforms as well as of the pension reform on productivity, employment and GDP. The assessment suggests that the reforms could increase the level of GDP by 1% within the first five years following the reform and by 2% within the first ten years (Table 1). At the 10-year horizon, about 20% of the effect is due to higher employment, while the remaining part is due to higher productivity. Details on the reforms that are taken into account in the analysis are found in the Annex.

**Table 1. The impact of recent structural reforms on GDP over 5 and 10 years**

	in percent		
	GDP	Via Employment growth	Via Productivity growth
<b>Impact after 5 years</b>			
Product Market Reform	0.7		0.7
Labour Market Reform	0.2		0.2
Pension reform	0.1	0.1	
<i>Total</i>	<i>1.0</i>	<i>0.1</i>	<i>0.9</i>
<b>Impact after 10 years</b>			
Product Market Reform	1.3		1.3
Labour Market Reform	0.3		0.3
Pension reform	0.4	0.4	
<i>Total</i>	<i>2.0</i>	<i>0.4</i>	<i>1.6</i>

1. OECD estimates for the impact of product market reform include changes to the product market regulation (PMR) as captured by the change in the OECD PMR indicator between 2008-2013, announced privatisations and reforms via EU commitments. The 2008-2013 change in the PMR is assumed to start having an effect on growth two years before other reforms.
2. Impact on the labour market reform is assessed via the effect of the change in the employment protection legislation (EPL) on growth.
3. Effect of the pension reform is based on a judgement and assesses the effect on employment via increased incentives for older people to stay in the labour market.

*Source: OECD calculations.*

The quantitative assessment accounts for two types of reforms (1) past reforms which have already been implemented and (2) additional measures which have been announced and approved by the parliament.

The quantitative assessment adopts the same methodology to estimate the effects of structural reforms as the OECD uses for the assessment of G20 countries' reform commitments in the Brisbane Action Plan. First, each reform measure is evaluated in terms of quantifiable variables, including standard OECD indicators where necessary. These indicators are typically the Product Market Regulation (PMR) indicators and the Employment Protection Legislation (EPL) indicators. Then a series of equations relate each reform measure to their expected effects on productivity and/or employment. The simulation results for Slovenia are obtained assuming that the structure of the economy corresponds to the average of France, Italy and Spain.

The quantitative assessment primarily focuses on reform measures for which the estimated effects are relatively well-established and straightforward to be understood. It relies on existing OECD empirical studies of the links between structural policies and productivity or employment, and covers the following areas: *i*) product market reform, *ii*) labour market reform (reform of employment protection legislation) and *iii*) pension reform.

## Product market reform

By spurring competition product market reform can accelerate the convergence in productivity levels to the most technologically advanced economies. Stronger competition encourages firms to become more efficient and to invest in innovation and knowledge-based capital. It also increases growth and employment by encouraging the creation of new companies – through lower barriers to entrepreneurship – and the expansion of existing ones that can take advantage of new markets, products or processes. Product market reforms can also boost aggregate productivity by enhancing the country's capacity to re-allocate capital and labour from declining or slow-growing to fast-growing sectors.

Slovenia's overall regulatory framework is among the most restrictive in the OECD, which stems largely from the pervasive state involvement in the economy. But there is also room to reduce the complexity of regulatory procedures and administrative burdens imposed on new companies. To tackle these issues, a number of reforms to the business environment have been implemented. Specifically, between 2008 and 2013, the government introduced simpler rules on starting a business, reduced administrative burdens on new companies and sole proprietors and established single contact points for getting information on all notifications and licenses. Additionally, the parliament approved a list of 15 companies to be privatised and the government committed to privatising state-owned banks. By early 2015 five companies were privatised and the remaining ones are in the process of being privatised. Slovenia also has to implement reforms as part of the completion of the European Telecom Single Market, the Third EU Energy Package and the EU's commitment to open the railway market for competition.

Together, the already implemented product market reforms and those to which Slovenia is committed should boost productivity and GDP by around 0.7% within the first five years after the reforms and by another 0.6% within the following five years.

The Slovenian government has also implemented a number of growth-enhancing product market reforms that cannot be quantified within the OECD's framework. Examples are the 2013 improvements in insolvency procedures, which should facilitate the restructuring of companies, and the establishment of the Slovenian Sovereign Holding (SSH) in April 2014, which should improve the management of the state-owned assets and improve corporate governance.

## Labour market reform

Reforms that reduce the stringency of employment protection legislation (EPL) and reduce the costs of hiring and firing can support growth by facilitating the allocation of labour resources. They make it easier for firms to respond quickly to changes in demand or technological advancements that require the reallocation or downsizing of staff. A study by Bassanini et al. (2009) supports this view, showing that stringent EPL weakens productivity in sectors where labour turnover is "naturally" high.

Before the 2013 labour reform, Slovenia was among the OECD countries with the strongest protection of workers on permanent contracts and no direct costs for terminating fixed-term contracts. The aim of the reform was to increase labour market flexibility and decrease labour market duality. The reform introduced greater flexibility by simplifying administrative procedures related to hiring and firing and shortening notice periods and lowered the costs of permanent employment contracts by reducing severance payments. For fixed-term contracts, it introduced redundancy payments and limited to two years the maximum duration of a fixed-term employment for a given job. In the case of termination, employers' costs are now the same for both contract types.

According to a survey by the Bank of Slovenia (2014) only 14% of companies reported a change in their human resources policy due to the new legislation. Still, evidence points, however, to a slight reduction in labour market duality as the share of permanent contracts among new hires increased from 24% to 28% within a year (IMAD, 2014). The OECD framework estimates the productivity and GDP effects of reduced protection of individuals with permanent contracts at 0.2% in the first five years after the reform. In the following five years a somewhat smaller effect is expected, so that the total GDP and productivity effects after ten years amount to around 0.3%.

The OECD framework does not allow quantifying the reform of student work that came into force in February 2015. Student work had been a major factor behind labour market duality, as it benefited from a preferential tax and regulatory treatment. The very welcome reform introduced a minimum hourly gross wage rate for student work, together with healthcare and pension contributions. Students will now accumulate years of pensionable service from their work. These changes make student work more comparable to regular employment contracts regarding costs, while maintaining its greater flexibility.

### Pension reform

A pension reform that increases older people's incentives to stay in the labour market, for instance by reducing the implicit tax on continued work or raising the statutory retirement ages, should have a positive effect on employment and, via better labour utilisation, on GDP.

The pension reform that Slovenia launched in 2013 strengthened the link between contributions paid and pensions received and equalised the statutory retirement age for men and women – for both genders the statutory retirement age will be gradually raised to 65 years by 2020. The reform increased penalties for early retirement (the pension is reduced by 0.3% per month of retirement before the statutory retirement age) and introduced a bonus for continued work (the pension is increased by 1% for every three-month period of work beyond the statutory retirement age with a maximum bonus of 12%). The new measures have helped slowing down the inflow of new applicants into the pension system (MDDSZ, 2014), though this has to be seen in the context of a strong inflow into the pension system just before the reform became effective.

OECD estimates suggest that the pension reform will boost GDP by 0.1% in the first five years after the reform and by another 0.3% within the following five years. This GDP effect comes through a rise in employment, which will increase by 0.2% within the first 5 years of the reform and another 0.2% within the following 5 years. The contribution of employment to GDP growth is disproportionately larger at the 10-year horizon despite the similar pace of employment growth because the 10-year effect assumes that the capital stock increases by as much as employment to recover the pre-reform level of the return to capital.

### Changes in the fiscal and banking framework

The Slovenian government has also introduced a number of changes to the fiscal and banking framework, which could not be quantified within the OECD's framework. Nonetheless, these changes can be expected to contribute positively to economic growth and stability in Slovenia. The reforms to the fiscal framework are expected to limit public expenditure growth in the future via a fiscal rule that requires a balanced budget over the medium term and to improve the collection of revenues via measures countering tax evasion. This is expected to lower public debt and free resources for more growth-friendly spending.

The measures in the banking sector should have helped to restore confidence and bring interest rates on public debt down to more sustainable levels. The weakened banking system was recapitalised and some non-performing assets were transferred to the newly established Bank Asset Management Company (BAMC). BAMC has the power to seek a quick resolution of impaired assets. Additionally, bank supervision is being strengthened. The National Assembly passed a law establishing a bank resolution fund, which will become operational in 2015 and will be financed by banks and managed by the central bank. In addition, a macro-prudential institutional framework has been established by the Bank of Slovenia.

## Annex: Reforms taken into account in the quantification exercise

Reform area	Reform content
<b>Product market reform</b>	
Various product market reforms during 2008-13	Reforms include improvements in the governance of state-owned assets, reductions in the government's involvement in network sectors, a shortening of the number of days required to open up a business, the introduction of single contact points for getting information on all notifications and licenses to open up a business, and the simplification of regulatory procedures and administrative burdens on start-ups and sole proprietors.
Privatisation	The parliament approved a list of 15 companies to be privatised. By early 2015 five companies had been privatised and the remaining ones are in the process of being privatised. The government has also committed to privatise state-owned banks.
EU commitment on Single Telecom Market	A legislative package for the completion of the European Telecom Single Market was voted by the European Parliament in April 2014 and has to be approved by the EU Council. The proposed package would strengthen network neutrality rules across borders and cut international roaming charges in the EU. Following an agreement reached with the EP in February 2014, the Council adopted the Directive on broadband cost reduction on 8 May. EU Member States must now adopt national provisions to comply with the new Directive by 1 January 2016 and they must apply the new measures from 1 July 2016.
EU commitment in the energy sector	In the energy sector the priority for the coming years should be the completion of the energy internal market through the transposition and implementation of the Third Energy Package, which should be achieved by the end of 2014. Its major elements concern the unbundling of networks, the strengthening of the independence and power of national regulators, and the improvement of the functioning of retail markets.
EU commitment in transport	In transport, the main priority is the opening of the railway market for competition through, among other things, the separation between infrastructure and services and open procedures for public service obligations. These issues are addressed by the Fourth Railway package proposed by the European Commission. In June 2014, the Council reached political agreement on the draft directives on the interoperability and safety of European railways and the draft regulation on the European Railway Agency. Together, these three legislative acts make up the technical pillar of the Fourth Railway package.
<b>Labour market reform</b>	
Employment Protection Legislation	Several measures to increase labour market flexibility and reduce segmentation were implemented in April 2013: reduced notice periods and severance payments for permanent employees, introduction of severance payments for temporary contracts, simplification of administrative procedures related to hiring and firing, introduction of quotas to agency workers.

---

**Pension reform**

Retirement age	The retirement age is being equalised for men and women and will be gradually raised to 65 years by 2020. Under the previous system, men could retire at 63 and women at 61. Also, the age at which a person may retire at a full pension if he/she has 40 years of actual employment (or periods for which contributions were paid with regard to maternity, sick leave or unemployment) was raised from 58 to 60.
Early and deferred retirement	The reform increased penalties for early retirement and increased rewards for continued work. In case of early retirement, the pension is reduced by 0.3% per month of retirement before the statutory retirement age. Conversely, a bonus is provided for deferred retirement, with the pension being increased by 1% for every three-month period of work beyond the statutory retirement age. The maximum pension bonus a person can obtain is limited to 12%.
Pension base	The calculation of the pension base takes into account the 24 consecutive years of insurance that are most favourable for the individual, as opposed to the 18 years under previous system.

## **ORGANISATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT**

The OECD is a unique forum where governments work together to address the economic, social and environmental challenges of globalisation. The OECD is also at the forefront of efforts to understand and to help governments respond to new developments and concerns, such as corporate governance, the information economy and the challenges of an ageing population. The Organisation provides a setting where governments can compare policy experiences, seek answers to common problems, identify good practice and work to co-ordinate domestic and international policies.

The OECD member countries are: Australia, Austria, Belgium, Canada, Chile, the Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Israel, Italy, Japan, Korea, Luxembourg, Mexico, the Netherlands, New Zealand, Norway, Poland, Portugal, the Slovak Republic, Slovenia, Spain, Sweden, Switzerland, Turkey, the United Kingdom and the United States. The European Union takes part in the work of the OECD.

OECD Publishing disseminates widely the results of the Organisation's statistics gathering and research on economic, social and environmental issues, as well as the conventions, guidelines and standards agreed by its members.

### **OECD "Better Policies" Series**

The Organisation for Economic Co-operation and Development (OECD) aims to promote better policies for better lives by providing a forum in which governments gather to share experiences and seek solutions to common problems. We work with our 34 members, key partners and over 100 countries to better understand what drives economic, social and environmental change in order to foster the well-being of people around the world. The OECD Better Policies Series provides an overview of the key challenges faced by individual countries and our main policy recommendations to address them. Drawing on the OECD's expertise in comparing country experiences and identifying best practices, the Better Policies Series tailor the OECD's policy advice to the specific and timely priorities of member and partner countries, focusing on how governments can make reform happen.

# THE 2012 LABOUR MARKET REFORM IN SPAIN: A PRELIMINARY ASSESSMENT

December 2013

**THE 2012 LABOUR MARKET REFORM IN SPAIN:  
A PRELIMINARY ASSESSMENT**

**DECEMBER 2013**

## FOREWORD

This report provides an initial evaluation of the comprehensive reform of the Spanish labour market undertaken in 2012. The report was commissioned to the OECD by the Spanish government and it complements the evaluation of the 2012 labour market reform undertaken by the Labour Ministry (Ministerio de Empleo y Seguridad Social (MEySS)) and presented in September 2013.

The evaluation presented in this report should be considered preliminary and mainly confined to the short-time impact of the reform, given the fact that only a short amount of time has passed since the reform was undertaken and the complexity of assessing the impact of such a comprehensive reform.

The objective of this report is to describe the key components of the 2012 reform and place them in the context of the evolution of labour market institutions in other OECD member countries, with a particular focus on collective bargaining and employment protection legislation. The report also assesses the impact of the reform on the ability of firms to adjust wages and working time to cope with demand shocks (so-called internal flexibility), as well as the flows in the labour market for different types of contracts and the overall duality of the Spanish labour market. The report also considers what complementary reforms would be required to improve the effectiveness of the labour market reform, in particular in the area of active labour market policies.

The work on this report was carried out by the Directorate for Employment, Labour and Social Affairs (ELS) of the OECD. The report was prepared by Andrea Bassanini and Josep Mestres, with statistical assistance from Thomas Manfredi. It benefited from the many useful comments by Stefano Scarpetta (ELS Director), Mark Keese (Head of the Employment Analysis and Policy Division) as well as by staff in the OECD Economics Department.

The co-operation of Spanish Authorities in providing the data used in this report is gratefully acknowledged. José Ignacio García Perez kindly performed the estimations of competing-risk hazard models on social security data. Moreover, staff in the Spanish Labour Ministry provided useful comments on previous drafts. Nonetheless, the OECD Secretariat bears full and sole responsibility for this report.

This work is published on the responsibility of the Secretary-General of the OECD. The opinions expressed and arguments employed herein do not necessarily reflect the official views of the Organisation or of the governments of its member countries.

## EXECUTIVE SUMMARY

This report provides an initial evaluation of the impact of the comprehensive reform of the Spanish labour market undertaken in 2012. This assessment is complementary to the evaluation performed by the *Ministerio de Empleo y Seguridad Social* (2013). Nonetheless, the findings presented here should be considered as preliminary, given the short amount of time that has elapsed since the reform was introduced and the complexity of assessing the impact of such an extensive reform.

### ***The reform has promoted the internal flexibility of firms...***

One of the key elements of the reform is the greater priority given to collective bargaining agreements at the firm level over those at the sectoral or regional level and the greater possibility given to firms to opt-out from a collective agreement and adopt internal flexibility measures to limit job destruction. In addition, the extension of collective bargaining agreements after their end date if no new agreement is reached is now limited to a maximum period of one year. Dismissal regulations have also been modified, redefining the conditions for fair dismissal, reducing monetary compensations in the case of unfair dismissal and eliminating the requirement of administrative authorisation in the case of collective redundancies. Moreover, a new permanent contract for full-time employees in small firms has been introduced with an extended trial period of one year.

### ***...and reduced dismissal costs for permanent workers***

The labour market reform has improved the *de jure* flexibility of the collective bargaining system in a way rarely found before the crisis both in Spain and in other countries of the Euro area. OECD indicators on employment protection legislation (EPL) indicate that the reform has significantly reduced the rigidity of the Spanish legislation on dismissals. Nevertheless, severance pay for permanent workers in Spain remains among the highest in OECD countries, despite the significant reduction in compensation for unfair dismissal brought about by the reform.

### ***The reform has contributed to significant wage moderation...***

The changes of internal-flexibility and collective-bargaining regulations have contributed to the significant wage moderation observed in Spain over the past year, even if part of this moderation is the result of protracted adverse cyclical conditions and public-sector wage cuts. While this wage moderation is affecting workers' living standards, there is already evidence that it has started yielding its dividends in terms of employment performance and has contributed to save jobs. Moreover, once growth is restored, the greater scope for firm-level collective bargaining could allow a better reflection of productivity gains into wages. Overall, the Spanish economy appears to have made substantial progress in achieving wage moderation, even if continuous monitoring of the effects of the reform in this area is advisable, and the government must be ready to implement further action if performance worsens. In addition, trends in income inequality should be monitored in order to guarantee that cost and benefits of the reform are equally shared.

### ***...and increased hiring on permanent contracts...***

The reform has contributed to promote hiring, in particular on permanent contracts. The empirical analysis in the report suggests that the reform could be considered responsible for about 25 000 new permanent contracts each month, with the effect concentrated in small and medium firms (those below 100

employees). The reform has also contributed to containing the duration of the unemployment spells, in particular due to faster transitions into permanent contracts for those workers entering unemployment after a temporary job. The analysis also shows some signs that separations decreased after the reform, especially for temporary contracts, possibly resulting from the greater use of internal flexibility measures as an alternative to contract termination. All these findings point to a positive effect of the reform in dampening the widespread segmentation of the Spanish labour market, although the impact is so far small and it will take time before the duality of the labour market is considerably reduced.

***...even if, prior to the August 2013 legal change, it also led to a decline in collective dismissals***

By contrast, the reform decreased collective dismissals more than any visible effect on individual dismissals, probably due to the increased procedural uncertainty that followed the elimination of the requirement for administrative authorisation – and the consequent increase in judicial uncertainty – as well as the extension of the circumstances in which companies making these dismissals have to pay a tax and carry out a special training and relocation plan. These factors are also probably one of the main drivers behind the lack of effect of the reform on hiring on permanent contracts by large employers. In that respect, the Government quickly reacted by addressing some of the key elements of procedural uncertainty through a new legislative changes in August 2013. It is too early to say, however, whether these changes will suffice to significantly reduce judicial uncertainty concerning collective dismissals in the future.

***The reform has the potential to boost productivity growth and competitiveness...***

Reforms of dismissal regulations, by enhancing labour reallocation, have the potential to boost productivity growth in the long-run. Drawing from a simulation exercise based on the experience of OECD countries over a long period of time, the report suggests that the reform could potentially boost labour productivity growth in the long run by about a ¼ of a percentage point annually in the business sector (excluding agriculture, mining, fuel and professional services).

***...but should be accompanied by further effort to promote greater competition in product markets and efficient activation policies***

The full impact of the reform on job creation will depend however on complementary reforms in other areas. In particular, reforms in product and service markets will not only increase competition and boost productivity, but also improve labour market performance. The effectiveness of active labour market policies is also very important in order to successfully place unemployed workers into jobs. The changes introduced recently in this area go in the right direction, but a careful evaluation of these recent reforms is necessary to ensure that the Spanish income support system to the unemployed and employment services are able to effectively and quickly encourage and help the unemployed to find work.

***While a good step, further actions could be envisaged***

Overall, the 2012 labour market reform appears to have brought more dynamism into the Spanish labour market and is a step towards the reduction of its widespread segmentation and the increase of the competitiveness of the Spanish economy in the medium term. Nevertheless, additional adjustments could be envisaged in order to ensure that the objectives of the labour market reform are fully attained.

In particular, the government could consider treating unlawful collective dismissals as any other type of unfair dismissal (as in most other OECD countries), limiting the possibility of ordering reinstatement to cases of discrimination and prohibited grounds. In addition, some of the specific, additional costs of collective dismissals for employers introduced by the reform could be rolled back.

The evidence presented in the report also suggests that the trial period is too short for firms that are not eligible for the *contrato emprendedores*. The duration of maximum trial periods for other permanent contracts could be made longer, particularly in those cases in which this duration is currently much shorter than in other OECD countries.

Finally, a greater convergence of employers' costs of termination for permanent and temporary contracts would be desirable. This will be already the case by 2015 for firms with less than 25 employees – for fair terminations – due to a severance-pay subsidy in place for these firms and the schedule of increases in severance pay for fixed-term contracts approved in 2010. Nevertheless, the government could consider deepening this convergence process, notably by reducing ordinary severance costs for large employers to align them closer to the OECD and European averages.

## INTRODUCTION

The global financial and economic crisis hit the Spanish labour market particularly hard. The harmonised unemployment rate in Spain reached 26.7% in October 2013, the second highest in the OECD area (only exceeded by Greece) and more than three times the OECD average (7.9%). Since the start of the crisis, the number of unemployed has increased by more than 4 million persons in Spain. Even more worryingly, long-term unemployment – defined as those unemployed for 12 months or more – as a share of all unemployment has risen from 19.1% in the fourth quarter of 2007 to 50.4% in the third quarter of 2013. Despite this massive increase in unemployment, the wage component of unit labour costs in the business sector was slow to adjust. It did not decline in the first four years of the crisis, and its level at the end of 2011 was above that at the onset of the crisis.

The deterioration of the competitiveness of the Spanish economy dates back to the beginning of the 2000s, but the further decline during the early phases of the crisis and the upsurge of unemployment led to a reaction by the Spanish government with a series of structural reforms. A first labour reform in 2010 – among other provisions – increased severance pay for temporary contracts (fully effective by January 2015 only) and generalised the severance pay subsidy scheme to all employers and types of dismissal for permanent contracts signed after the date of approval of the reform.<sup>1</sup> A second major reform was undertaken in February 2012. This reform consisted of two main elements. First, it gave priority to collective bargaining agreements at the firm level over those established at the sector or regional level and made it easier for firms to opt-out from a collective agreement and implement internal flexibility measures as an alternative to job destruction. In addition, the previous practice of extending collective bargaining agreements after their end date in the case that no new agreement could be signed by the social partners was limited to a maximum period of one year. Second, the provisions of Spain's Employment Protection Legislation (EPL hereafter) were significantly modified, reshaping the definition of fair economic dismissal, reducing monetary compensations for unfair dismissal and eliminating the requirement of administrative authorisation for collective redundancies. In addition, a new permanent contract for full-time employees in small firms was introduced, entailing an extended trial period of one year.

The objective of this study is to evaluate the labour market impact of the 2012 reform. In particular, this report makes a threefold contribution. First, it places the reforms of the Spanish labour market in the context of reforms in other OECD member countries. Second, it assesses the impact of the reform on wage moderation and labour costs, in particular by looking at the way it appears to have shaped the evolution of labour costs in the business sector. Finally, it evaluates the impact of the reform on labour market flows and duality, by looking at hiring, separations, tenure on the job and duration of unemployment spells. As far as the labour market duality is concerned, special attention is devoted to flows to and from permanent contracts. To the extent that certain provisions included in the reform apply only to firms below certain size thresholds (notably 50 and 25 employees), whenever possible, the effects are estimated separately for firms above and below these thresholds.

Almost paradoxically, the comprehensive nature of the 2012 reform makes its evaluation a difficult task. In fact, the inclusion of a large number of provisions, sometimes explicitly targeted at different groups, does not allow the identification of a suitable control group. The reform also occurred in the

---

1. This provision was, however, never fully implemented and partially withdrawn in 2012 (see Section 1).

middle of a double-dip recession, at a time when the economic juncture restarted to deteriorate after a short recovery that was so hesitant that employment continued to fall. More importantly, this evaluation comes only after a short time since the reform was implemented, and in many cases only short time series are available.<sup>2</sup> In addition, several amendments and implementation decrees were made at different dates after the approval of the reform in February 2012. For all these reasons, the evaluation exercise provided in this report should be considered as very preliminary and mainly limited to the short-time impact of the reform.

The report is organised as follows: Section 1 describes the main features of the 2012 reform. Section 2 places these features into an international perspective by comparing the Spanish institutions of collective bargaining and employment protection legislation with those of other European and OECD countries, documenting the country's progress vis-à-vis those of other countries. Section 3 summarises the results of several econometric exercises evaluating the impact of the reform on unit labour costs and various types of worker flows, disentangling the effects by firm size whenever possible. The full details of the econometric estimations are provided in the Annex. A simulation of the likely long-run impact of the reform on productivity growth is also presented in this section. Section 4 briefly discusses interactions with other policies, with particular attention to active labour market policies, stressing the potential role of other institutions in maximising the employment dividend of the reform. The last section provides some concluding remarks and sets forth a few recommendations for further action in this area.

## 1. Key components of the 2012 reform

The 2012 Spanish labour market reform was approved by the government in February 2012 as a *Real Decreto Ley 3/2012* and confirmed with no substantial modifications as the *Ley 3/2012 de medidas urgentes para la reforma del mercado laboral*<sup>3</sup> by the Spanish Parliament in July 2012. Subsequently, several legal provisions were introduced in order to implement the reform. This comprehensive reform modified several aspects of the Spanish labour market regulation, including collective bargaining rules and collective and individual redundancy procedures and costs.

The objective of the reform of collective bargaining was to restore competitiveness by aligning labour costs more closely with productivity and allow employers to exploit more easily internal flexibility measures as an alternative to dismissals in the presence of adverse company shocks, thereby preserving jobs and reducing employment losses in bad times (see Section 2.1 below). The reform gave priority to collective bargaining agreements at the firm level over those at the sector or regional level, so that collective agreements could adjust more closely to the specific needs of a firm. In addition, firms can now opt-out more easily from a collective agreement and pursue internal flexibility measures. For example employers can introduce unilaterally changes in working conditions (wages, working hours, work schedules) whenever there are objective economic, technical, production or organisational reasons.<sup>4</sup> In addition, in the absence of an agreement with workers' representatives, the employer willing to opt out may now unilaterally refer the matter to arbitration by a public tripartite body ("*Comisión Consultiva Nacional de Convenios Colectivos*", CCNCC hereafter). Once settled by arbitration, this kind of dispute is not fully reviewable by labour courts, since arbitration decisions may be challenged before a court only on very limited grounds (see Gomez-Abelleira, 2012). Finally, collective bargaining agreements can now be

2. The analysis contained in this report is based on data that were available in early September 2013. It covers therefore time series up to July 2013.
  3. The full text of the Decreto Ley 3/2012 is available at [www.boe.es/boe/dias/2012/02/11/pdfs/BOE-A-2012-2076.pdf](http://www.boe.es/boe/dias/2012/02/11/pdfs/BOE-A-2012-2076.pdf) and the one of the Ley 3/2012 at [www.boe.es/boe/dias/2012/07/07/pdfs/BOE-A-2012-9110.pdf](http://www.boe.es/boe/dias/2012/07/07/pdfs/BOE-A-2012-9110.pdf).
  4. More precisely, this possibility existed also in the previous legislation but was extended by the 2012 reform.

prolonged for a maximum period of only one year after their end date (the so-called period of *ultra-activity*), in order to provide incentives to social partners to renegotiate rapidly new agreements adapted to any changes in economic conditions.

Substantial changes were also introduced with respect to dismissal legislation, with the objective of making the labour market more dynamic and less segmented, thereby increasing productivity growth and reducing the share of precarious jobs (see Section 2.2 below). The reform redefined the conditions for a fair dismissal, improving further upon the greater clarity already introduced by the 2010 reform. While actual or expected losses or loss of competitiveness remain fair reasons for an economic dismissal, the new law specifies that a dismissal is always justified if the company faces a persistent decline (over three consecutive quarters) in revenues or ordinary income.<sup>5</sup> In addition, and perhaps more important, the firm does not have to prove that the dismissal is essential for the future profitability of the firm.<sup>6</sup>

Monetary compensation for unfair dismissal was reduced to 33 days' wages per year of seniority up to a maximum of 24 months, compared to the previous severance pay of 45 days up to a maximum of 42 months' wages.<sup>7</sup> At the same time, the reform removed a worker's right to interim wages between the effective date of dismissal and the final court ruling (except in the case when the worker is reinstated). This made redundant the option employers often used before the reform of declaring a dismissal unfair even before a conciliatory procedure took place and paying upfront the corresponding severance payment (the so-called "*despido exprés*", which was de facto the most commonly-used dismissal mechanism by employers prior to the reform),<sup>8</sup> which was therefore removed.

As regards collective dismissals, the reform eliminated the requirement of administrative authorisation for collective redundancies while maintaining the obligation of good-faith negotiations with unions before serving individual notice, in line with the current legislation in most OECD countries. In addition, the new law specifies more precisely the objective reasons under which an employer can undertake a collective redundancy. In exchange, the firm has to carry out a special training and relocation plan for those workers that have been dismissed if the collective dismissal affects over 50 workers. Moreover, the reform has enlarged the set of cases in which the employer must pay a tax if the collective dismissal involves workers aged 50 years or more. In addition, in March 2013, the *Real Decreto Ley 5/2013*, made liable to this contribution, under certain circumstances, not only firms making profits in the period preceding the dismissal, but also those that end up making profits in at least two of the four years following the dismissal, thereby making this contribution dependent on future performance.<sup>9</sup> In August 2013, further legislative changes were made in order to reduce uncertainty regarding collective dismissal procedures. The *Real Decreto Ley 11/2013*<sup>10</sup> clarifies how the negotiating committee must be established

5. The new law specifies that extraordinary income should not be taken into account.
6. Case law seems to confirm that the *de jure* relaxation of the definition of fair economic dismissal also holds *de facto*. See for example the decision of the *Sala de lo Social del Tribunal Supremo* dated 20 September 2013 (STS 20-9-13, Rec. 11/2013) that specifies that judges have to establish that the economic reasons alleged by the employer are truthful and serious, but must not assess whether the employer's decision is an appropriate managerial decision.
7. In the case of fair dismissal, however, severance pay remains at 20 days' wages per year of seniority up to 12 months' wages.
8. In fact, before the reform, workers were not eligible to backpay in the case of *despido exprés*. This was the only advantage of choosing this procedure for the employer.
9. The full text available at [www.boe.es/boe/dias/2013/03/16/pdfs/BOE-A-2013-2874.pdf](http://www.boe.es/boe/dias/2013/03/16/pdfs/BOE-A-2013-2874.pdf). However, this decree also restricts the application of this tax only to those firms where the share of dismissed workers aged 50 years or more is higher than the share of workers over 50 in the firm.
10. The full text is available at [www.boe.es/boe/dias/2013/08/03/pdfs/BOE-A-2013-8556.pdf](http://www.boe.es/boe/dias/2013/08/03/pdfs/BOE-A-2013-8556.pdf).

and the documentation that the employer has to provide at the beginning of the negotiation round. Perhaps more importantly, the same decree sets unambiguous limits to the power of courts to declare void the collective redundancy procedure, thereby ordering reinstatement of workers (with backpay) with no possibility for employers to opt for additional compensation in lieu of reinstatement (as in the case of unfair individual dismissal, see above). Furthermore, it limits the cases where workers can individually challenge collective dismissal agreements.

A new full-time permanent contract for small firms (under 50 employees) was created (*Contrato de Apoyo a Emprendedores*) that allows an extended trial period of one year for firms that have not engaged in collective or unfair dismissals in the 6 months before the starting date of the contract. This “*contrato emprendedores*” includes several hiring incentives and fiscal rebates for firms under 50 employees. In addition, the reform extended the existing subsidy equivalent to 40% of ordinary severance pay (8 days per year of service, paid by a wage guarantee fund – FOGASA) to all cases of fair dismissal in the case of firms with less than 25 workers.<sup>11</sup> As the 2010 reform raised severance pay for fixed-term contracts to 12 days per year of service (from 2015), small employers will be soon liable for disbursing the same amount for open-ended and temporary contracts, in the case of fair dismissal.

Other changes introduced by the reform include the re-instatement of the two-year maximum period for extension of standard fixed-term contracts (which was temporarily suspended in August 2011), an increased flexibility to use part-time contracts and the *Contrato de formación y aprendizaje* as well as new regulations for training provision and the authorisation given to private temporary placement agencies to operate in the domain of placement of unemployed workers, alongside the public employment system.

## 2. The labour market reform in international perspective

At first glance, the 2012 reform summarised in the previous section touches upon a number of key aspects of the Spanish labour legislation. However, its depth and effectiveness must be rigorously assessed on two main grounds by: i) comparing the new Spanish institutions with those prevailing in other OECD countries (in particular, European countries); and ii) assessing the effects of the reform on labour market performance. This section provides a comparison of the evolution of Spanish labour legislation against those prevailing in other countries, by looking first at institutions regulating collective bargaining and internal flexibility and then at EPL. The empirical analysis of the effect of the 2012 reform on the performance of the labour market is then developed in the following section.

### 2.1. Collective bargaining

In most of continental Europe, wages are typically bargained collectively and most workers are covered by collective agreements through administrative extension (cf. Table 1). The rationale for collective bargaining arises from the asymmetry in contracting between individual workers and employers regarding both access to information and bargaining power. Labour laws provide framework conditions for collective bargaining to emerge so as to rebalance the bargaining power between employers and workers. Hence, all else equal, compared with a situation in which only individual contracts prevail, the more developed the collective-bargaining system is, the higher the bargaining power of workers is likely to be.

---

11. In principle, a transitory norm contained in the 2010 reform, had already extended this 8-day-per-year subsidy to all firms, including even in the case of unfair dismissal (for contracts stipulated after June 2010). However, another transitory norm of the same reform that was planned to enter into force in 2012 also established that higher social security contributions would have been levied on contracts eligible for the severance pay subsidy. These transitory norms were cancelled by the reform.

Notes: 1 refers to central level of bargaining, 2 to sectoral and 3 to local. \* = low ; \*\* = medium ; \*\*\* = high, qualifying the relative importance for bargaining levels and the importance of coordination. The table should be read by line, as it describes the relative importance of the various bargaining levels and of the extension of, and derogation from, sectoral agreements within each country. It is not meant to provide an assessment of the relative importance of a given bargaining level across countries.

a) Collective bargaining systems incurred significant changes in Greece, France, Ireland, Italy, Portugal and Spain after the start of the global financial crisis; they are not included here as the available information is not systematic for all other countries.

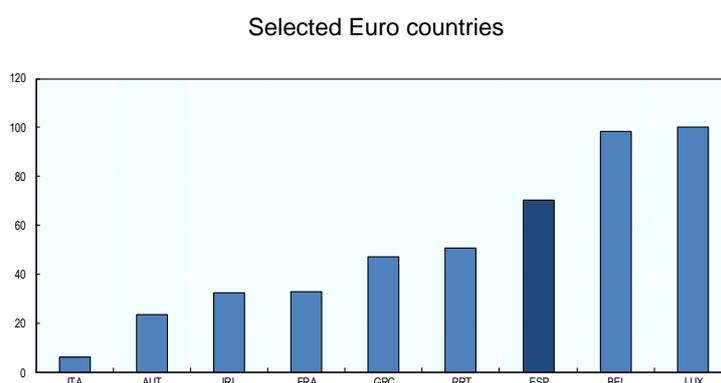

Source: OECD (2012), Du Caju et al. (2008), van Klaveren (2011).

From a theoretical point of view, the level at which collective bargaining takes place can yield substantially different outcomes. In general, aggregate flexibility brought about by centralised or coordinated bargaining allows wage-setters to internalise externalities associated with wage increases and delivers better outcomes in terms of unemployment, inflation and innovation by incumbent firms. Conversely, relative flexibility associated with firm-level bargaining typically spurs innovation by entrants and allows a better adjustment of wage growth to firm-level productivity growth, thereby allowing to save jobs in the presence of idiosyncratic shocks. By contrast, in the case of bargaining at the sectoral or regional level, cross-sector imitation often pushes wages upwards in times of boom and delays the required wage-adjustments in times of crisis, particularly in the presence of heterogeneous firm performances (see e.g. OECD, 1994, 2006, Flanagan, 1999, Haucap and Wey, 2004, Jimeno and Thomas, 2013).

In the 1990s, in a number of European countries where sectoral bargaining was playing a major role, governments pressed for national-level agreements. In this case, the key objective was often to limit the automatic indexation of wages to inflation. In fact, monetary integration ruled out external adjustment via the

exchange rate to compensate for losses in national competitiveness, and, starting from 1999 for EMU countries, the use of monetary policy instruments to adjust to asymmetric shocks. As a result, the burden of adjustment to economic imbalances and shocks shifted increasingly onto the labour market. The outcome of this process was that, in most countries of the Eurozone for which data are available (see Figure 1), less than 50% of companies had an automatic indexation of wages at the onset of the crisis – and, in many countries, automatic indexation was not imposed by collective agreements but the result of independent company policies. In that respect, Spain was among the countries where indexation was more frequent – covering about 70% of firms – which contributed to the erosion of Spanish competitiveness before the crisis, as shown by the pre-crisis evolution of its unit labour costs in comparison with other Euro countries (see Figure 2).<sup>12</sup>

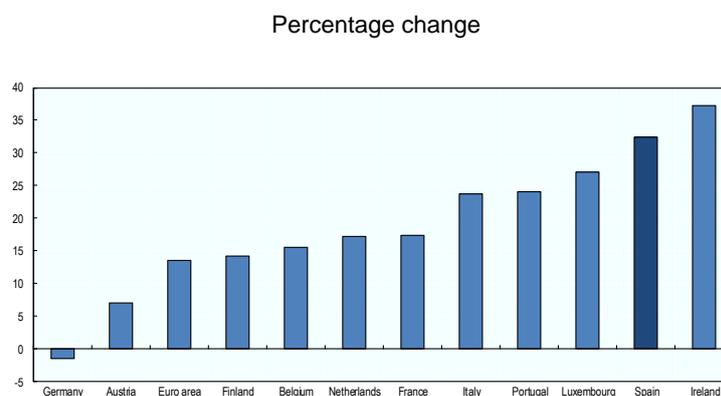

Figure 1. **Percentage of firms subject to a mechanism of adjusting base wages to inflation before the crisis**

Note: Only countries that joined the Euro before 2007 are included. Data for Greece are not available.

Source: Eurostat.

At the same time, in most OECD countries, the role played by collective negotiations at the firm/establishment level has increased, leading to a significant decentralisation of collective bargaining

12. However, other structural factors – such as the dynamics of the sectoral composition of the economy – are also responsible for this trend in unit labour costs.

systems since 1990. While this process often started in the 1980s for bargaining over working-time reduction, it has since extended to matters of pay. Decentralisation has taken place in two main ways: i) instead of setting standard wage increases, sectoral agreements increasingly provide a framework for firm-level agreements; and ii) sectoral agreements increasingly include derogation clauses, allowing firm-level agreements to depart from sectoral agreements in specified cases.<sup>13</sup>

The substance of sectoral agreements has been changing in many countries, leaving much more room for firm-level bargaining on wages. In some cases, the determination of average wage increases still takes place at the sectoral level, but the decision on how to distribute wage increases among employees is left to firm-level bargaining.<sup>14</sup> However, at least before the onset of the crisis, in most countries, including Spain, firms covered by a multi-employer agreement were bound to observe what is called the “*favourability principle*”, meaning that firm level agreements had to be more favourable to employees than higher-level agreements. As a result, firm-level bargaining resulted often in higher wages with respect to minima bargained at the sector level. For example, exploiting transitions from one regime to another, wages negotiated at the firm level are found to be higher in Denmark than those negotiated under sectoral agreements, even though significantly more dispersed (Dahl *et al.*, 2011). Similar results are found by Gørtzen (2010) and Rusinek and Rycx (2013) for Germany and Belgium.<sup>15</sup>

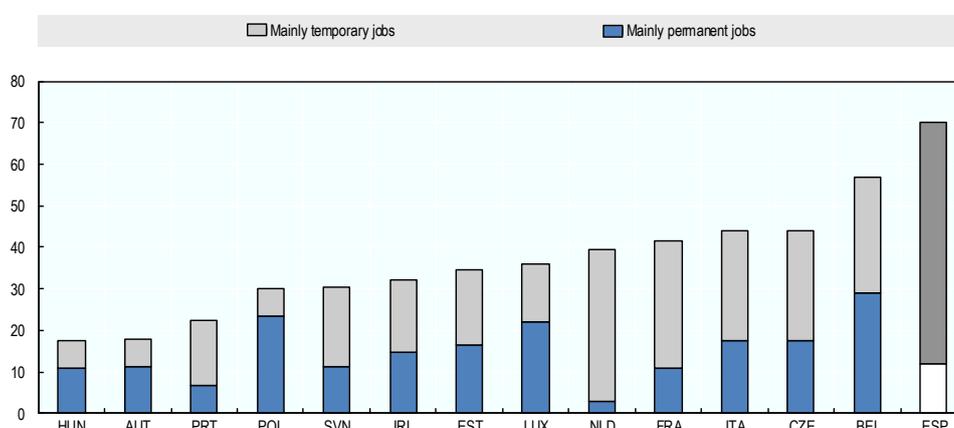

The inclusion of derogation clauses in sectoral, regional or national collective agreements, allowing firms to opt-out of higher-order agreements, has become more frequent, especially in Germany and Ireland. From a theoretical viewpoint, Jimeno and Thomas (2013) show that sectoral bargaining systems can deliver similar labour market performances as decentralised systems, if firms and workers are not prevented from agreeing to opt out of higher-level agreements. Derogation clauses are typically of two types: “hardship” or “inability-to-pay” clauses, which allow temporary deviations from higher-level agreements for firms facing economic difficulties; and “opening” or “opt-out” clauses, which can be invoked either by firms that cannot afford to meet the general standard, especially small and medium-sized enterprises, or by firms facing threats to future competitiveness and possible relocations of investment and production sites (Visser, 2004). In most countries, the use of derogation clauses remained limited before the crisis (see Table 1), with few exceptions. The “inability-to-pay” clause included in the central agreements since 2003 was regularly used in Ireland (van Klaveren, 2011). But, of particular note, actual use of these clauses expanded significantly in Germany.<sup>16</sup> In this country, industries covered by sectoral agreements allowing derogation clauses experienced greater net employment growth and lower job destruction (Brändle and Heinbach, 2010). This trend can be considered one of the most important factors that restrained the growth of unit labour costs in Germany before the crisis (see Figure 3).<sup>17</sup>

- 
13. In addition, the share of variable pay, by definition negotiated at the firm level, has been growing.
  14. This is a very common practice in Denmark and Sweden, and exists in Austria, Belgium, Germany and Italy. In the Netherlands, a large share of employees are covered by sectoral agreements which allow for choices between pay and working time to be decided at the firm level. In the Czech Republic, Denmark, and the Slovak Republic, industry-level agreements increasingly tend to set minima while actual wage increases for the rest of the pay scale are negotiated at the firm level (see OECD, 2012).
  15. In Germany, however, administrative extension of collective agreements is limited and occurs almost on a voluntary basis, except when automatic extension to all workers and companies of an industry is imposed by the Federal Ministry of Labour. Many employers adhere to the collective wage agreement concluded for their respective industry even if they are not member of a business association that signed it. Nonetheless, they have no obligation to do so. Nevertheless, new companies tend to resist applying branch-level collective agreements and, as a result, the proportion of workers covered by collective agreements has gone down over time, particularly in Eastern Germany (Düll, 2013).
  16. Increased use of derogation clauses resulted in cuts in basic pay, reductions in agreed wage increases, lower wage rates for job starters or reduction/suspension of bonuses (Keune, 2010; Haipeter and Lehndorff, 2009).
  17. Other factors to be mentioned, however, are the expansion of low-pay jobs and the reduction of workers covered by collective agreements

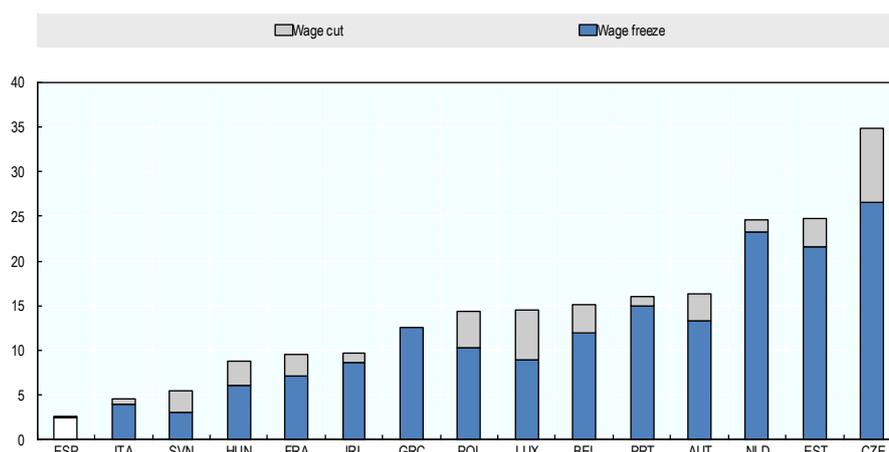

Even if derogation clauses were possible in Spain before the 2012 reform, they were seldom applied. Overall, the Spanish economy was typically characterised by a much stronger reliance on employment adjustments to absorb shocks. For example, before the onset of the crisis, the main adjustment strategy to a demand shock for about 70% of Spanish firms was to reduce employment— mainly by suppressing temporary jobs – while this strategy was preferred by only 40% of firms, on average, in other countries according to the Eurosystem’s WDN Survey (Figure 3, Panel A). In fact, wage cuts or wage freeze were very rarely undertaken by Spanish firms in the five years preceding the crisis in comparison with other countries (Figure 3, Panel B). Evidence from the follow-up WDN survey, conducted in the first months of the crisis, shows that, wage cuts and wage freezes remained much less frequent in Spain than in most other European countries, despite the severity of the 2008-2009 recession in the country (European Central Bank, 2010).<sup>18</sup>

Figure 3. Adjustment strategies to adverse shocks used by European firms before the crisis

Panel A. Percentage of firms for which job destruction is the main adjustment strategy to an adverse demand shock, 2007-2008

Panel B. Percentage of firms having frozen or cut wages between 2003 and 2008

Source: Eurosystem’s WDN Survey (Fabiani et al., 2010, Babecký et al., 2009, European Central Bank, 2010).

18. Some caution is required in the analysis of the follow-up WDN survey since it is smaller and with a larger non-response rate than the original survey.

In this context, the 2012 reform appears to have improved the flexibility of the Spanish collective bargaining system. In particular, the introduction of the principle of dominance of firm-level agreements on higher-level ones and the greater possibility of opting-out of collective agreements even in the absence of consensus among social partners at the company level represent potential instruments of internal flexibility that, as shown above, were hardly found both in Spain and the other European countries before the crisis. Whether or not there is evidence that these instruments are contributing to promote the competitiveness of Spanish firms is a question that will be examined in Section 3.

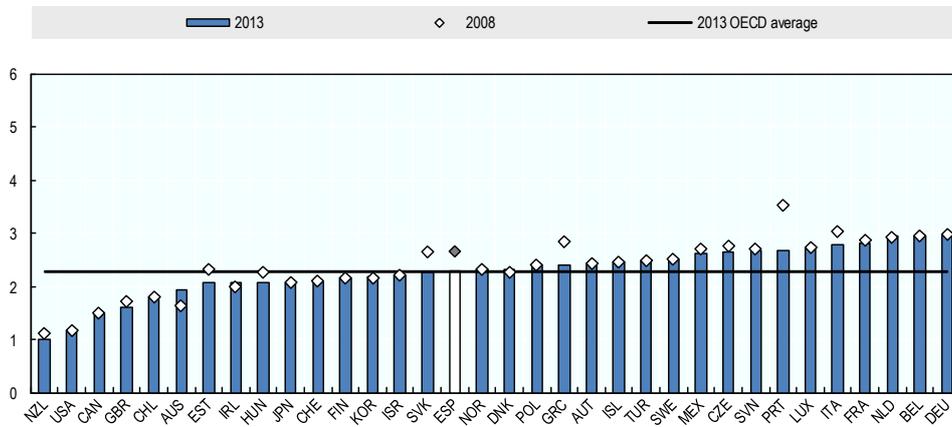

## **2.2. *Employment Protection Legislation***

There is a large body of theoretical and empirical research – summarised in OECD (2013a) among others – that suggests that hiring and firing regulations have a significant impact on the reallocation of labour resources, while the long-run impact on aggregate unemployment rates is, at best, small. Countries with relatively high employment protection are typically found to have lower hiring and separation rates and a slower resilience to output shocks. Moreover, there is evidence that in these countries stringent regulations stifle the allocation of labour to the most productive uses, thereby hindering productivity and economic growth. Perhaps more important in the Spanish case, if stringent employment protection on regular, open-ended contracts coexists with relatively easy access to fixed-term contracts, firms tend to react by substituting fixed-term for permanent contracts – due to the smaller cost involved with the termination of the employment relationship at the end of a fixed-term contract (see e.g. Boeri and Garibaldi, 2007; Bentolila et al., 2008, 2012; Jahn et al., 2012) – with no significant impact on employment and negative effects on productivity growth, in particular if the likelihood of contract conversion is small (see e.g. Dolado et al., 2012, Cappellari et al., 2012).

OECD indicators on EPL allow benchmarking cross-country differences in the stringency of hiring and firing regulations. These indicators quantify, for employers of large companies, the costs and procedures involved in dismissing individuals – or groups of employees – or hiring workers on fixed-term or temporary-work-agency contracts, as in force on the 1<sup>st</sup> of January of each year. The indicators concerning the regulations governing individual and collective dismissals of workers with regular, open-ended contracts, are perhaps the most useful for policy analysis. These indicators cover: i) procedural inconveniences that employers face when starting the dismissal process, such as notification and consultation requirements; ii) notice periods and severance pay, which typically vary by tenure of the employee; iii) difficulty of dismissal, as determined by the circumstances in which it is possible to fairly dismiss workers, as well as the repercussions for the employer if a dismissal is found to be unfair (such as compensation and reinstatement); and iv) additional restrictions for collective dismissals, such as additional delays, costs or notification procedures when an employer dismisses a large number of workers at one time. Although any quantification is inevitably a simplification (see e.g. OECD, 2013), and users need to be cautious in using these indicators to assess the relative position of a given country, the change in value of the summary indicator for regular contracts for Spain between 2008 and 2013 suggests that the recent reforms significantly reduced the rigidity of the Spanish legislation on dismissals (Figure 4).

The OECD indicators can also be used for a rough comparison, component by component, of the regulation in Spain with respect to other OECD countries. The Spanish economy appears now more flexible than the average OECD country in areas such as notification procedures and the length of notice periods (see Figure 5). In particular, notice periods were reduced in 2010 from 1 month to two weeks, independently from the length of service, which makes of Spain one of the OECD countries with the shortest notice periods, particularly for workers with a long tenure. Indeed, average notice periods in OECD countries are 3.5 weeks, 1.3 months and 2.7 months for workers with, respectively, 9 months, 4 years and 20 years of tenure at the time of dismissal (OECD, 2013b).

Figure 4. Protection of permanent workers against individual and collective dismissal, 2008 and 2013

Disaggregate components, 2008 and 2013

Note: Indicators vary from 0 (least restrictive) to 6 (most restrictive) and refer to rules applicable to large companies.

Source: OECD Employment Protection Database, 2013 update.

In contrast with a number of countries in continental Europe, Spanish workers have no right to reinstatement in the case of unfair individual dismissal<sup>19</sup> – except when dismissal is based on prohibited grounds (such as discrimination) – which provides greater certainty to employers about the cost of dismissal. This is somewhat counterbalanced by a level of monetary compensation for dismissal which is high in cross-country comparable terms. In fact, as far as large companies are concerned, Spain remains among the countries with the most expensive requirements as regards severance pay both in the case of fair and unfair dismissal. And this occurs despite the significant reduction in compensation for unfair dismissal brought about by the 2012 reform (see Section 1), which put additional compensation in this case more in line with the amounts paid in other countries (see Figure 5). More precisely, in the case of unfair dismissal, the typical monetary compensation in OECD countries is about 13.7 monthly wages at 20 years of tenure (against about 22 months in Spain after the reform). For the same length of service, ordinary severance pay in the case of fair dismissal is on average 6 monthly wages among OECD countries where dismissed employees are entitled to it, while it is equal to 10 monthly wages in Spain, in the case of companies with 25 employees or more. Finally, Spain is one of the only 7 OECD countries where workers in large companies are entitled to ordinary severance pay even if their job tenure is shorter than 1 year (see OECD, 2013b).

The situation is comparatively better for small firms, and improved further after the 2012 reform, insofar as the latter included several provisions targeted at them. In the context of the Spanish economy, where small firms represent a large share of total employment, this is an important potential source of dynamism for the labour market.<sup>20</sup> In particular, the severance-pay subsidy covered by the wage guarantee fund, which results in a 40% reduction of the burden of ordinary severance pay borne by employers with less than 25 employees, is applicable to all cases of fair dismissals after the 2012 reform. This policy action has put the cost of ordinary severance payment at the level of the OECD average for firms of that size – excluding those countries with no compulsory severance payments in the case of fair dismissal.

The case of the trial period is somewhat similar. For ordinary permanent contracts the maximum length of the trial period is on average shorter – and therefore more constraining – than in most other OECD countries (4 months in Spain against an OECD average of 5.1 months), and can be as short as two weeks in certain sector-level collective agreements. Nonetheless, the introduction of the “*contrato emprendedores*” (see Section 1) has *de facto* made the trial period for firms with less than 50 employees the longest within civil-law OECD countries.<sup>21</sup> This is particularly important since, although the reform has significantly relaxed the definition of fair dismissal for economic reasons, dismissal for personal reasons remains relatively difficult in Spain. In principle, therefore, the longer trial period should allow small employers to better experiment and screen new employees, reducing the risk of bad matches and thereby increasing hiring incentives. Indeed, there is evidence in the literature that the length of the trial period and the extent of reinstatement are usually the two EPL components with the greatest impact on labour reallocation (see Bassanini and Garnero, 2013). Yet, a very recent decision of a local court stated that, for certain occupations, a trial period as long as one year would be in violation of article 4.4 of the European

- 
19. However, reinstatement with backpay can be ordered when a collective dismissal is declared void by courts (see below).
  20. According to the OECD Structural Business Statistics, firms with less than 20 employees and less than 50 employees accounted for 50% and 62%, respectively, of the Spanish non-financial business-sector employment in 2010.
  21. Legal systems can be roughly divided in civil-law and common-law countries, the latter including Australia, Canada, Ireland, Israel, New Zealand, the United Kingdom and the United States. Common-law countries typically have lighter statutory regulations limiting the freedom of contracting parties. Beyond most US states and Canadian provinces, where claims for unfair dismissal cannot be filed, the United Kingdom has the longest trial period (2 years for all firms), followed by Ireland and Israel (1 year for all firms) and Australia (1 year for firms with less than 15 employees; see OECD, 2013b).

Social Charter, which stipulates the right to advance notice for all dismissed workers.<sup>22</sup> However, it is too early to say whether this argument will be incorporated into other court decisions in the future, and the consequences that this will have for the application of the reform. Nonetheless, to avoid these types of conflict with supranational legislation, a number of OECD countries have introduced the obligation of advance notice of dismissal even for workers in the last months of the trial period, when the latter is long.<sup>23</sup>

By contrast, before the reform, Spain was one of the few OECD countries where a specific administrative authorisation was required for collective dismissals. At the beginning of 2012, a similar institutional arrangement could be found only in Greece and Mexico where an administrative authorisation is required if no agreement is reached among social partners on the terms of the collective dismissal procedure. Yet, the administrative authorisation may help reducing uncertainty about the final cost for employers of dismissal decisions in countries where judicial review of these decisions is extensive and employers' choices can be nullified by the court. For example, in May 2013, France re-introduced the requirement of administrative authorisation in the absence of agreement among social partners in order to reduce the degree of judicial uncertainty generated by the possibility for courts of invalidating social plans associated with collective dismissals and, consequently, ordering the reinstatement of involved workers, sometimes several months after dismissal.

There is some evidence suggesting that the Spanish experience immediately after the 2012 reform closely resembles the French experience before the 2013 reform. Even if the litigation rate as regards collective redundancies appears to have remained low (below 5% according to estimates by Palomo-Balda, 2013), a large share of concluded proceedings concerning collective dismissals resulted in court rulings against the employer. And, in most of these cases, the judges ruled that the dismissal procedure was null and void and ordered the reinstatement of the affected workers with backpay – a novel situation in the Spanish labour market that was essentially inexistent before the 2012 reform (see Palomo-Balda 2013, Mercader-Uguina and de La Puebla-Pinilla, 2013, and Ministerio de Empleo y Seguridad Social, 2013).<sup>24</sup> In addition, in most cases, the court decisions against employers were not based on challenges to the alleged substantive reasons for dismissal but on the non-respect of the negotiation procedure, in particular as regards the determination of employees' representatives in the consultation committee, the incompleteness of the documentation provided by the employer at the start of the consultation process, or the lack of good faith in consultations. Given these outcomes, the low rate of litigation might not be fully

---

22. Juzgado de lo Social 2 de Barcelona (Sentencia 412/13, 19-11-2013).

23. This is the case, for example, in Germany, Ireland, Switzerland and the United Kingdom. Often these notice periods are, however, shorter than in the case of other permanent workers. Probationary periods, when too long, could also conflict with the requirements of the ILO Convention 158 for those countries which have ratified this convention (including Spain). Article 2 of this convention stipulates that probationary periods should be of reasonable duration. On this basis, in France (one country that signed Convention 158) the *Contrat Nouvelle Embauche* that was introduced in 2005 and allowed a 2-year trial period under certain conditions was subsequently annulled by the administrative high court because it was considered in violation of the ILO convention (see e.g. Lepage-Saucier et al., 2013). However, other countries that signed Convention 158 have long probationary periods. In Australia, for example, they are as long as one year, for small firms, and six months, for large firms, suggesting that these durations can well be considered as “reasonable”, at least conditional on firm size, even as regards the application of the ILO convention (see also the observations on Australia of the ILO Committee of Experts on the Application of Conventions and Recommendations, 2012). At the time of writing, Spanish labour unions have filed a complaint with the constitutional court concerning the possibility that the *contrato emprendedores* is in violation of Convention 158.

24. Before the reform, a judgement of nullity of a collective dismissal procedure that had been previously authorised by the labour authority was basically impossible without proving an explicit misbehaviour of the labour authority (see e.g. Mercader-Uguina and de La Puebla-Pinilla, 2013).

representative of the effective cost for employers, who might be either forced to give concessions during the negotiation phase or tempted to chain together a smaller number of individual dismissals over subsequent periods of three months in order to escape from collective dismissal regulations,<sup>25</sup> even though these chained series of dismissals would be in principle illegal if motivated by the same economic cause.

These shortcomings of the new regulations of collective dismissals have been recently addressed by the government with the approval of the *Real Decreto Ley 11/2013* in August 2013, which has more explicitly defined the requirements of the consultation procedure and the cases in which the dismissal can be declared void. In addition, the interpretation of the law has been further clarified by recent court rulings of the Supreme Court, specifying in particular that the absence of an agreement with unions do not justify per se the invalidation of the dismissal procedure and defining how extensively the consolidated accounts of a business group must be considered in assessing the justification of the dismissal decision.<sup>26</sup> It is too early to say, however, whether these interventions will prove sufficient to restore legal certainty as regards to the cost and outcomes of collective dismissals. Yet, albeit significantly reduced, the discretionary role of courts to invalidate a collective-dismissal procedure and order reinstatement remains substantial, at least on paper.

However, the reform has also increased certain, specific costs of collective dismissal by making compulsory to set a retraining and redeployment plan – in the case of dismissals involving more than 50 employees – and enlarging the set of circumstances in which a contribution to the treasury must be made (see Section 1). De la Puebla-Pinilla (2013) estimates these costs as substantial: the total cost of additional taxes and retraining/redeploying affected workers can be greater than the total amount of severance payments that the company would have disbursed had it been able to unfairly dismiss these workers.<sup>27</sup> These additional provisions have not been modified by the August 2013 revision of the reform.

Finally, the Spanish labour market is characterised by a high level of duality. At the onset of the crisis, 31.7% of wage and salary employment was on a fixed-term contract (Figure 6). This proportion went down significantly during the crisis, because of the extremely high rate of temporary job destruction, but remains among the highest in the OECD. The duality of the Spanish labour market emerges even more clearly from data on new hires. In 2007, 88.3% of new labour contracts were fixed-term, and this figure increased during the crisis peaking at 92.3% in 2011, to decline only slightly afterwards.<sup>28</sup> Although the share of

25. See for example “Los trabajadores de Pastas Gallo denuncian un ERE encubierto”, *El País*, 13 September 2013. Collective dismissal regulations must be applied if, within 90 days, the employer plans to dismiss: more than 10 workers in firms with less 100 employees; at least 10% of workers in firms with at least 100 and less than 300 employees; and 30 workers in firms with at least 300 employees.

26. See in particular the decisions of the *Sala de lo Social del Tribunal Supremo* dated 27 May 2013 (STS 27-5-13, Rec. 78/2012), 20 September 2013 (STS 20-9-13, Rec. 11/2013) and 25 September 2013 (STS 25-9-13, Rec. 3/2013). Moreover, future decisions of the Supreme Court are likely to build up a coherent body of case law that will help reducing further legal uncertainty. In fact, the 2012 reform, by allowing complaints concerning collective dismissals to be filed directly with regional labour courts, makes it possible for the Supreme Court to review all collective dismissal cases, as long as the party who has lost in the first instance lodges an appeal (Gomez-Abelleira, 2012).

27. According to Spanish legislation, if the number of dismissed workers within a period of 90 days is larger than the threshold triggering collective dismissal procedures, the dismissal is void if the firm does not implement the procedure at all. This implies that unfair dismissal (“*despido improcedente*”) is not an option open to employers in this case. As discussed above, however, in certain cases companies might decide to limit the number of affected workers, and/or chain individual dismissals over a long-period to avoid paying the higher costs associated with collective dismissals, even at the risk of having the individual terminations be ruled as unfair by a court.

28. Data on new contracts are from *Datos Estadísticos de Contratos*, published by the *Servicio Público de Empleo Estatal* (SEPE).

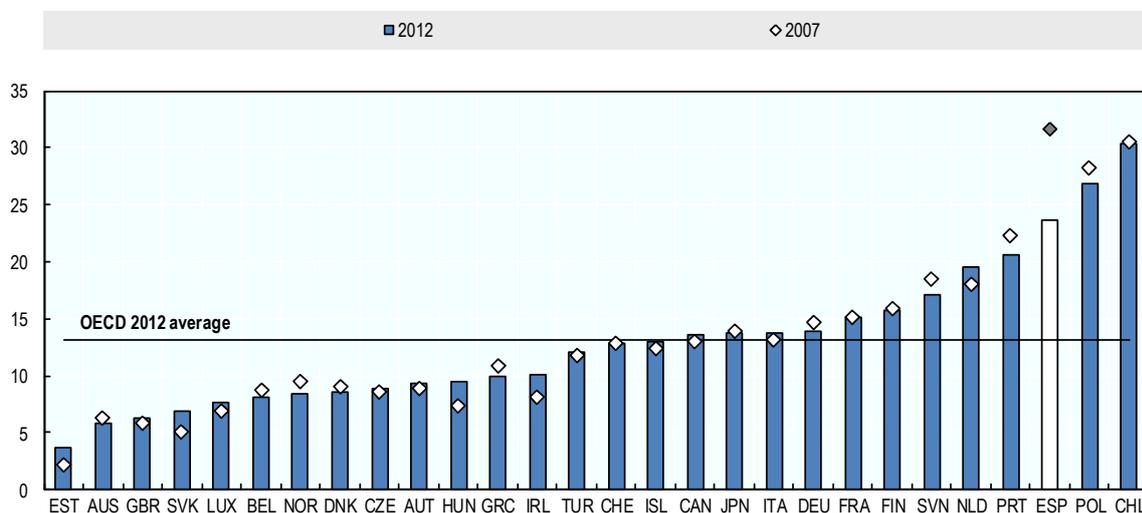

fixed-term contracts in new hires is typically high in countries with stringent EPL, the Spanish labour market appears to perform particularly badly in this respect. For example, in both France and Italy the share of fixed-term contracts in new hires was much lower in 2011 (78% in both countries; see Paraire, 2012, and Ministero del Lavoro e delle Politiche Sociali, 2012).

Despite the high share of fixed-term contracts among new hires, the rate of contract conversion is extremely low in Spain. Only 3% of all new contracts are converted from fixed-term into permanent contracts. From a worker perspective this implies that transitions across temporary and permanent statuses are rare (e.g. Güell and Petrongolo, 2007). Even taking a longer horizon, the evidence is qualitatively similar: about one-third of the workforce that is found in temporary jobs at a certain point in time permanently rotate across temporary jobs and unemployment for at least 6 to 8 years, and even when they obtain an open-ended contract it is unstable (Garcia-Serrano and Malo, 2013). In other words, the Spanish labour market is dynamically segmented between well-protected “insiders” and precarious “outsiders”, who cycle between temporary jobs and unemployment with little hope of transiting towards permanent jobs.

In contrast with the legislation of most other countries, severance pay is due in Spain in the case of termination of a temporary contract at the initiative of the employer even at the end date, but its amount is small.<sup>29</sup> In 2010, the government approved a small reform of these payments, entailing their increase from 8 to 12 days per year of service by 2015. While for firms with less than 25 employees this will equalise the cost of fair termination between temporary and permanent contracts, this cost will remain nonetheless much lower for temporary contracts in the case of large firms – and for all firms in the case of unfair dismissal.

Figure 6. Incidence of temporary employment, 2007 and 2012

Employees with temporary contracts as a percentage of total employees

29. France, Israel and the United Kingdom are among the few OECD countries where temporary workers have a statutory right to severance pay even in the case of fair termination.

### 3. The labour market impact of the 2012 reform

Almost paradoxically, the comprehensive nature of the 2012 labour market reform makes its evaluation a difficult task. In fact, the inclusion of a large number of provisions, sometimes explicitly targeted at different groups, does not allow the identification of a well-defined control group. The reform also occurred in the middle of a double-dip recession, at a time when the economic juncture started to deteriorate again after a short recovery that was so hesitant that employment had continued to decline (see e.g. Ministerio de Empleo y Seguridad Social, 2013). This suggests that one of the few available methods to analyse the role of the reform in the recent evolution of the Spanish labour market is through regression-discontinuity models in which the effect of the reform is identified through discontinuous patterns occurring at the time of its enforcement and the business-cycle is modelled through observable controls and non-linear time trends (see Box 1). The fact that discontinuous patterns of labour market performance occurring around February 2012 are used to identify the effect of the reform makes it impossible to distinguish its impact from that of other institutional changes occurring around the same date. Obviously, the analysis developed in this section assesses only the joint effect of the reform and other simultaneous institutional changes.

#### Box 1. Estimating the impact of the 2012 reform using regression-discontinuity models

The estimation strategy followed in this report identifies the joint effect of all the provisions included in the reform by comparing labour market performance before and after February 2012. The key identification assumption is that, conditional on control variables included in the model, labour market performance evolves in a relatively smooth way, so that any discontinuous jump in performance can be attributed to the labour market reform (and other institutional changes occurring simultaneously, such as the Agreement on Employment and Collective Bargaining 2012-2014, signed by the main business associations and trade unions – CEOE, CEPYME, CCOO and UGT – in January 2012). In order to properly isolate the effect of the reform from that of the business-cycle (which is key for the validity of the smoothness assumption), the estimation models capture economic fluctuations by controlling for the standardised unemployment rate, changes in registered employment (at the regional level when microdata are used) and, most importantly, polynomial time trends up to the 5<sup>th</sup> order. Baseline specifications include a polynomial trend up to the highest order  $n$  such that the  $n$ -th term is significant. However, except when specified otherwise, results are robust both to changes in the order of the polynomial and to its exclusion from the specification. When a sufficiently long number of periods is available after the reform, polynomial trends are alternatively included as either homogeneous (same parameters before and after the reform) or heterogeneous (different parameters before and after the reform), and the robustness of the results to these different specification choices is assessed. The results are also robust to the use of other controls for the business cycle such as changes in industry-level value added or productivity growth or the FEDEA index of economic activity (see the Annex for details). Finally, other variables capturing compositional effects (region, industry, workforce composition, etc.) are included in each specification. As suggested by Card and Lee (2008), since the identification is based on a time discontinuity, standard errors are always adjusted for clustering at least on time (and, where relevant, also to other dimensions).

Obviously, misspecification of the empirical model might lead to identify a discontinuous shift in performance around the date of a reform even when this shift occurs before the reform (and cannot therefore be attributed to it). To validate the empirical model, therefore, placebo tests need to be run. These tests consist in setting in the empirical model an earlier date than the actual reform date to estimate possible discontinuities. If discontinuous shifts in performance are really induced by the reform, then no effect should be found at these anticipated dates. This is indeed the case for all the results discussed in this report, where placebo tests are run by anticipating the date of the reform by up to 9 months.

A second issue concerns possible manipulations around the threshold. For example, if the introduction of the *contrato emprendedores* were anticipated, employers eligible for the subsidy could delay hiring to after the reform in order to enjoy the subsidy. However, the details and the breadth of the reform were never mentioned in the programme of the PPE before the November 2011 elections that the party won and was not made public until well after the inaugural address of Prime Minister Rajoy made in front of the parliament at the end of December 2011. It is therefore reasonable to assume that if threshold manipulation occurred, that is if firms postponed certain choices until the approval of the reform, this phenomenon concerned, at worst, only the period January-March 2012. Under these assumptions, threshold manipulation is not an issue in the regressions estimated on quarterly data because the outcome of any firm choice, which was delayed from January to March 2012, is included in the same quarter, with no effect on the average outcome of the quarter. In the case of estimates based on monthly data, baseline models are re-estimated excluding the period from January to March 2012 from the sample as an additional robustness check.

A number of provisions, however, also either entered into force, *de jure* or *de facto*, after the date of approval of the main reform (February 2012) or were modified since then. This is the case, for example, of the norms regulating the CCNCC (*Real Decreto*, 1362/2012, approved in September 2012), of those regulating collective dismissal procedures and associated financial contributions for firms (*Real Decretos* 1483/2012 and 1484/2012, approved in October 2012), of the entry into force of binding time limits for the automatic extension of expired collective bargaining agreements (July 2013) and of the corrections made to collective-dismissal regulations in March and August 2013 (*Real Decretos Ley* 5/2013 and 11/2013; see Section 1 above). This makes more difficult to identify unambiguously discontinuous patterns in the data.

Last but not least, the assessment presented here is performed shortly after the reform. Available data cover at best 18 months in the post-reform period, but sometimes much less. Thus, estimates presented in this section measure only the short-term impact of the reform. In addition, the effect of structural reforms often takes time to materialise since economic agents adapt slowly to new conditions. This is likely to be particularly the case in Spain due to the role of the courts in applying the new legislation and the time that it will take to the judicial system to develop a uniform body of case law. All of these factors suggest great caution in interpreting the results, which at best can be interpreted as preliminary and only roughly indicative of a general trend.

### 3.1. Labour costs

As discussed in the previous sections, the objective of the reform of collective bargaining and internal flexibility was to restore the competitiveness of Spanish firms, by ensuring a better adaptation of wages to productivity developments. The available, preliminary evidence concerning new collective bargaining agreements suggests that wage increases with respect to observed and expected inflation have been restrained in 2012 and 2013 (Ministerio de Empleo y Seguridad Social, 2013, BBVA, 2013a). In addition, even though the share of workers covered by automatic indexation of wages has not fallen significantly, the impact of indexation clauses on wages appears to have become smaller, probably due to a more flexible application of these clauses in the new contracts, following the recommendations of the 2012 general agreement among social partners (Izquierdo et al., 2013).

Spain has been one of the European countries where unit labour costs have declined the most since 2012 (Figure 7). Between the fourth quarter of 2011 and the second quarter of 2013, unit labour costs declined by 3.9%. This has occurred despite the withdrawal of most hiring subsidies decided by the government in July 2012, which undoubtedly pushed labour costs upwards (see Ministerio de Empleo y Seguridad Social, 2013). In the same period, in most European countries, labour costs were either on a moderate rise or decreasing only slightly.<sup>30</sup> Even in Portugal, which has also been hit hard by the crisis, the drop in unit labour costs was 3 percentage points smaller than in Spain.

One needs to be cautious, however, in attributing these developments to the 2012 labour market reform. In particular, as argued elsewhere (BBVA, 2013b), wage moderation was particularly important in the public sector in 2012 for reasons that have nothing to do with the labour market reform, albeit closely related to the the government's action to fiscal consolidation.<sup>31</sup> To shed light on this issue, therefore, Figure 8 presents the evolution of unit labour costs separately for the business sector and non-market services including the public administration. While the effect of the drop in civil servant's wages is clearly visible in the data for the fourth quarter of 2012, significant wage moderation is also observable outside the

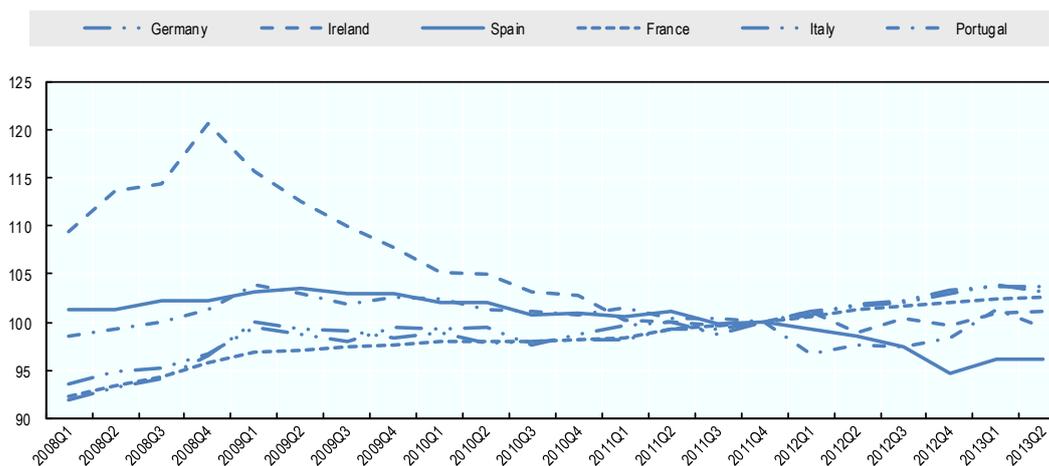

30. Data for Greece are not available. The only other European country with a significant drop in unit labour costs is Cyprus (-7.3%).

31. In Spain most civil servants have two bonus payments, equivalent to about one month's salary, paid twice a year, at Christmas and in July. The Christmas bonus was withdrawn in 2012, thereby resulting in a significant fall in 2012 public sector wages, concentrated in the fourth quarter.

public sector. In fact, in the non-agricultural business sector, unit labour costs, excluding non-wage costs, decreased by 3.2% between the fourth quarter of 2011 and the second quarter of 2013, that is an average annual drop of about 2.1%. By contrast, the growth of these costs was substantially flat in the three years preceding the reform.

Figure 7. Evolution of unit labour costs in selected European countries, 2008-2013

Figure 8. Evolution of the wage and salary component of unit labour costs in Spain, by industry, 2008-2013

Q4-2011 = 100

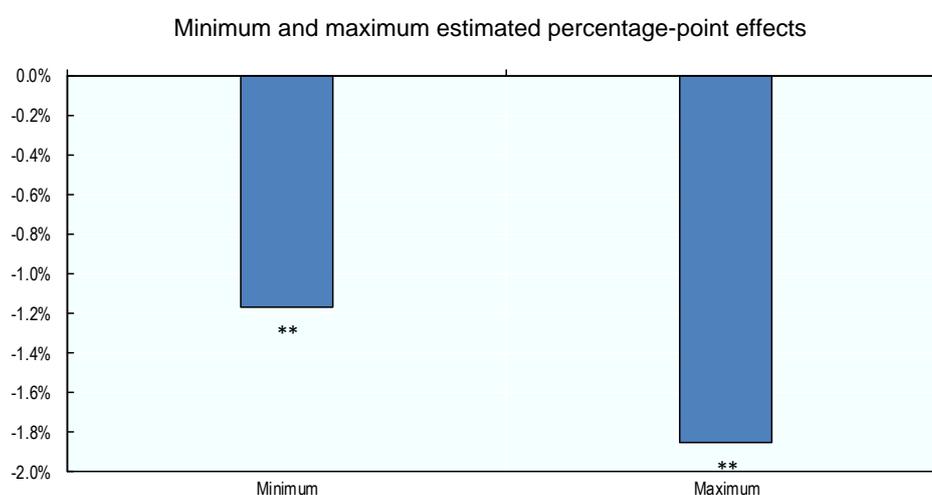

Note: Data are seasonally adjusted and adjusted for working days. The business-sector excludes agriculture.

Source: OECD calculation on the basis of the Spanish Quarterly Labour Cost Survey and Quarterly National Accounts.

Again, the evidence presented in Figure 8 is not sufficient to quantify the effect of the labour market reform on labour cost competitiveness of Spanish firms. The prolonged recession has undoubtedly affected the evolution of wages, and its effects are indeed visible in terms of wage moderation before the reform (see Figure 6 and 7). However, the econometric models estimated for this report using industry-level data allow for netting out the effect of the business-cycle, inflation and productivity growth on the dynamics of labour costs per hour worked so that the effect of the 2012 labour market reform (and the 2012 national agreement among social partners) can be identified through the discrete shift in the growth of labour costs observable since the beginning of 2012 (see Box 1). The estimated results suggest that the 2012 reform (together with the 2012 collective agreement) induced a drop in the growth of unit labour costs in the business sector of between 1.2% and 1.9% (Figure 9).<sup>32</sup> It can be concluded, therefore, that more than 50% of the observed drop in unit labour can be attributed to the 2012 reform.

Figure 9. Estimated impact of the 2012 reform on the year-on-year growth of business-sector labour costs

*Note:* Estimates obtained using different specifications of a model in which the year-on-year the industry-level harmonized index of wage and salaries per hour worked is regressed on the unemployment rate, a polynomial trend (industry-specific in certain specifications) and year-on-year changes in industry workforce composition, the consumer price index and either log employment or log labour productivity. Significance levels are obtained by adjusting errors for clustering by industry and time. The estimates are based on industry data disaggregated at the 1-digit level. \*\*: significant at the 5% level.

*Source:* OECD estimation on the basis of the Spanish Quarterly Labour Cost Survey, Quarterly National Accounts and the Encuesta de Población Activa. See Annex for the detailed estimation method and results.

These results are consistent with those of a recent Bank of Spain report (Izquierdo et al., 2013), which present estimates of firm-level wage-growth equations with similar controls and show that wage residuals appear to have been significantly smaller after the 2012 reform. Moreover, the available evidence suggests that, while this wage moderation is affecting workers' living standards, it is already yielding some dividends in terms of employment dynamics. There is in fact a consensus among the few available empirical studies published since the reform that, with respect to what is predicted by the negative GDP

32. Although formally the harmonized index of labour cost per hour worked is used as a dependent variable, to the extent that controls capturing productivity developments are included in all specifications, the estimated effect can be interpreted as estimates of the impact on unit labour costs (excluding non-wage costs). Moreover, even though labour shedding is likely to be behind part of the effect visible in raw data (cf. Figure 8), since the marginal worker who become unemployed is likely to be the one with the highest wage with respect to his/her productivity, this is unlikely to be the case for the econometric estimates, to the extent that cyclical fluctuations are rigorously controlled for in several ways in the regression models (see Box 1 and the Annex).

growth observed in the past six quarters, net employment contraction was below expectations, suggesting therefore a positive impact of the reform on employment growth. Consistent findings on this issue emerge from the simple comparison of the time series of GDP and employment growth (Ministerio de Empleo y Seguridad Social, 2013), the examination of the residuals of an estimated Okun's law (Izquierdo et al., 2013) and the estimation of structural models (De Cea and Dolado, 2013, BBVA, 2013a). The further improvement of employment trends in the third quarter of 2013 (see e.g. Puente and Font, 2013) seems to confirm this consensus.

### 3.2. Changes in worker flows

#### Hiring rates

As discussed in Section 1.3, flexibility-enhancing reforms of hiring and firing regulations are, first and foremost, expected to increase hiring and separations. However, it can be argued that the expected impact of the 2012 reform on dismissals and separations is *a priori* ambiguous, due to the new incentives to adopting internal-flexibility measures, thereby preserving jobs. Therefore, hiring behaviour by firms is perhaps the most important area where the reform of hiring and firing regulations can be assessed.

Figure 10 underlines the dramatic contraction of the hiring rate during the crisis. Quarterly data from the Labour Force Survey (*Encuesta de Población Activa – EPA*) show that the share of employees with less than 3 months of tenure in total business-sector employment decreased substantially in 2008 (from 10.7% in the first quarter of 2008 to 7.4% in the first quarter of 2009, once corrected for seasonality).<sup>33</sup> It then recovered a little (up to 8.5%) in 2010 when the Spanish economy exhibited some timid signs of recovery and then dropped again to 7.4% in the last quarter of 2011, pushed down by the worsening of economic activity. Since then, the hiring rate has stabilised at 7%-8%.

To what extent can the stabilisation of the hiring rate in spite of the adverse cyclical conditions be attributed to the 2012 reform? The estimated results obtained from hiring-rate regressions – which carefully control for business-cycle influences and composition effects – cautiously suggest<sup>34</sup> that the reform had a moderate but positive impact on hiring (See Box 1 for the general methodology and the Annex for details concerning all estimates presented in this section). Indeed, all other things equal the reform is estimated to have increased the hiring rate by about 8% (that is raising the share of employees with less than 3 months of tenure by about 0.6 percentage points),<sup>35</sup> so that the hiring rate would have kept falling until the beginning of 2013 in the absence of the reform (see Figure 10, Panel A).

The evolution of total hiring is mirrored by the dynamics of hiring on regular, open-ended contracts, even though the latter typically represents only about one tenth of total hires. Again, the fall of hiring on permanent contracts appears to have stabilised in 2012, followed by strong signs of an upward movement in the second quarter of 2013. The econometric estimates suggest that the fall in permanent hiring would

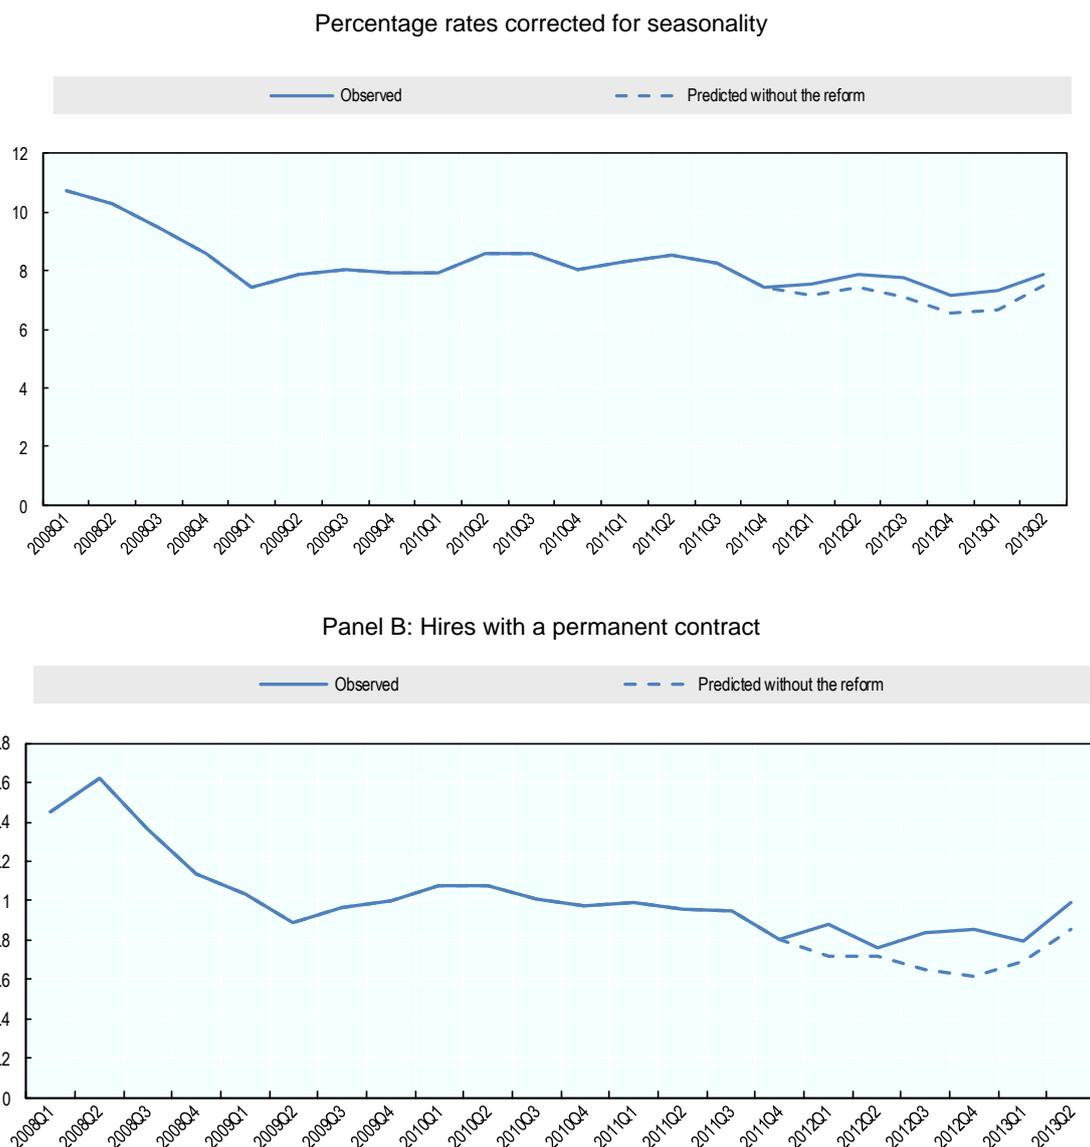

33. Following OECD (2009, 2010), hiring rates are defined here as the share of workers hired in a given period of time and that are in employment at the end of the period (counting therefore each worker only once) divided by total wage and salary employment in that period. This definition is not uncommon in the literature (see e.g. Davis et al., 2006, and Golan et al., 2006) and it is the most appropriate in the case of data from the EPA.

34. It must be underlined however that, in contrast with other econometric analyses presented in this section, the statistical significance of the estimated effect of the reform on the hiring rate depends on the assumptions made on the polynomial trend used to capture business-cycle fluctuations (see the Annex).

35. More precisely, the microeconomic estimates show that the probability that an employee has job tenure shorter than 3 months increased by about 0.6 percentage points. This probability is the micro-level equivalent of the hiring rate at the aggregate level.

have been more pronounced in the absence of the reform than what is predicted in the case of total hiring (Figure 10, Panel B). In fact, the reform is estimated to have increased the hiring rate on permanent contracts by 13%. In addition, the increase in permanent hiring in the aftermath of the reform appears to be concentrated in full-time positions. In particular, the reform is estimated to have increased the hiring rate of full-time open-ended contracts by 18% on average, while no significant effect is found as regards part-time permanent contracts. By contrast, with an estimated positive effect of only 7% – insignificant in certain specifications – the effect on hiring of temporary employees appears more limited.

Figure 10. The evolution of hiring rates in the non-agricultural business-sector, 2008-2013

Note: The figure presents observed and predicted percentage ratios of workers with no more than 3 months of job tenure on total employment in the reference week. "Predicted without the reform" indicates the empirical prediction of what the hiring rate would have been in the absence of the reform, based on empirical estimates of the baseline model for the individual probability of having tenure equal to 3 months or less. Panel A refers to all new hires and panel B to new hires with a permanent contract.

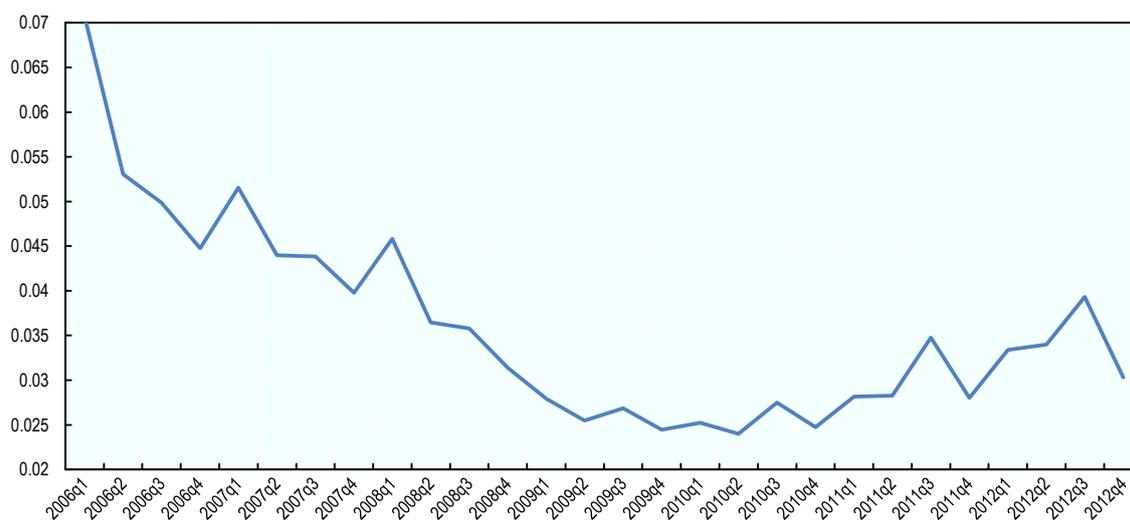

Source: Estimations on the basis of data from the *Encuesta de Población Activa* (EPA). See Annex for the detailed estimation method and results.

### Transitions from unemployment to employment

Not only are flexibility-enhancing reforms of EPL expected to increase hiring, but they are also expected to reduce unemployment duration and speed up transitions towards permanent employment. Social security microdata, in which employment histories of individuals affiliated with social security can be followed over time, are ideally suited for this analysis. For a large random sample of workers affiliated with social security, the *Muestra Continua de Vidas Laborales* (MCVL) registers all employment and unemployment spells as well as the start and end dates, thereby measuring accurately their exact duration and allowing to link these durations with previous employment spells. Figure 11 shows the proportion of individuals leaving unemployment for permanent employment for a sample of Spanish workers aged 16-64 over the period 2006 to 2012, conditional on being unemployed at that point in time.<sup>36</sup> The proportion of unemployed individuals moving to a permanent job has decreased significantly over the period, in particular due to the increase in the number of unemployed since the start of the crisis. However, there are some signs of recovery in the most recent quarters. But to what extent can these developments be attributed to the 2012 reform?

Figure 11: **Average proportion of unemployed individuals leaving unemployment to permanent employment**

Quarterly average of monthly rates, 2006-2012

Note: For each quarter, the figure presents the average monthly the proportion of individuals leaving unemployment to permanent employment for a sample of Spanish workers aged 16-64 over the period 2006 to 2012, conditional on being unemployed at that point in time. The sample includes all individuals who have been unemployed at least one day.

Source: Muestra Continua de Vidas Laborales (MCVL).

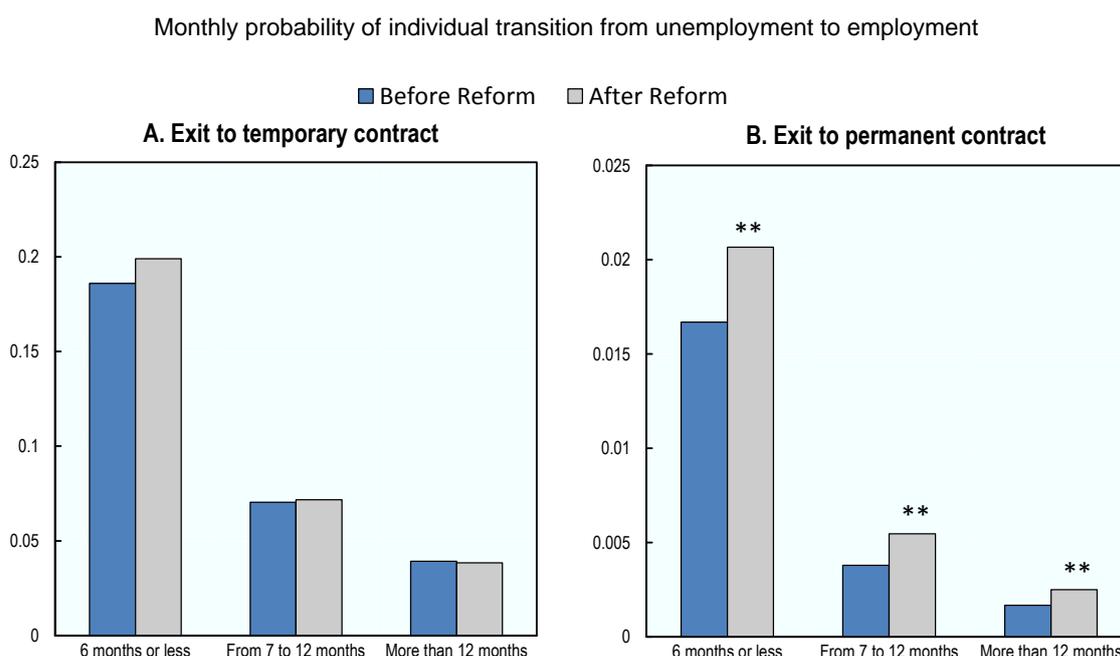

The estimation results indicate that the 2012 reform increased the probability of leaving unemployment and entering employment for any unemployment duration.<sup>37</sup> The effect of the reform is

36. The rates presented in Figure 11 are not comparable with those presented in Figure 10 for three main reasons: i) averages of monthly (instead of quarterly) transitions are considered; ii) the denominator is represented by the pool of unemployed workers (instead of wage and salary employees); and iii) individuals not registered as unemployed are not included, which leaves out youth searching for their first job and people transiting directly from job to job without spending at least one day in unemployment (however the latter are less than 3% of all employees in the data).

37. Estimations of competing-risk hazard models on the MCVL – whose results are presented in this section – were run by José Ignacio Garcia-Perez (University Pablo de Olavide) in close cooperation with the OECD

significant only as regards the probability for the unemployed of being hired on a permanent contract, which has increased by 24%, on average, during the first 6 months in unemployment where most transitions occur (Figure 12). The estimated percentage effect is even greater at longer unemployment durations (more than 40%), although obviously smaller in percentage points. By contrast, the effect of the reform on transitions to a temporary contract is small and insignificant.<sup>38</sup> Thus, for unemployment durations no longer than 6 months, the reform appears to have raised the share of exits from unemployment to permanent employment in total exits from unemployment by about 14%, taking the point estimates at face value.

Figure 12: Exit from unemployment by type of contract and unemployment duration

Note: The figure presents the average of estimated monthly probabilities of individual transition from unemployment to employment just before (February 2012) and after (March 2012) the reform, by type of new contract and unemployment duration (less than six months, from 7 to 12 months and more than 12 months). The sample includes all individuals who have been unemployed at least one day. Unemployment durations are censored at 30 months in unemployment. Panel A refers to exits from unemployment to temporary contracts and Panel B to exits from unemployment to permanent contracts. The asterisks refer to the significance level of the estimated effect of the reform on each transition probability. \*\*: significant at the 5% level.

Source: Estimations on the basis of data from the Muestra Continua de Vidas Laborales (MCVL). See Annex for the detailed estimation method and results.

Perhaps more important, the reform appears to have boosted transitions towards permanent employment significantly more for those that had a temporary contract prior to becoming unemployed,

---

Secretariat, which however bears full and sole responsibility for the interpretation of the findings and the choice of the modelling strategy.

38. However, in absolute terms, the estimated effect on transitions to permanent contracts is not significantly greater than that on transitions to temporary contracts. For example, taking point estimates at face value, in the first 6 months of unemployment, the average probability of a monthly transition to a temporary job increased from 18.6% to 19.9% due to the reform whereas the average transition to permanent employment increased only from 1.7% to 2.1%. Moreover, it cannot be excluded that these relative patterns are also due to the gradual increase in severance pay for fixed-term contracts, starting in January 2012 but approved by the parliament in 2010 (see Section 2.2).

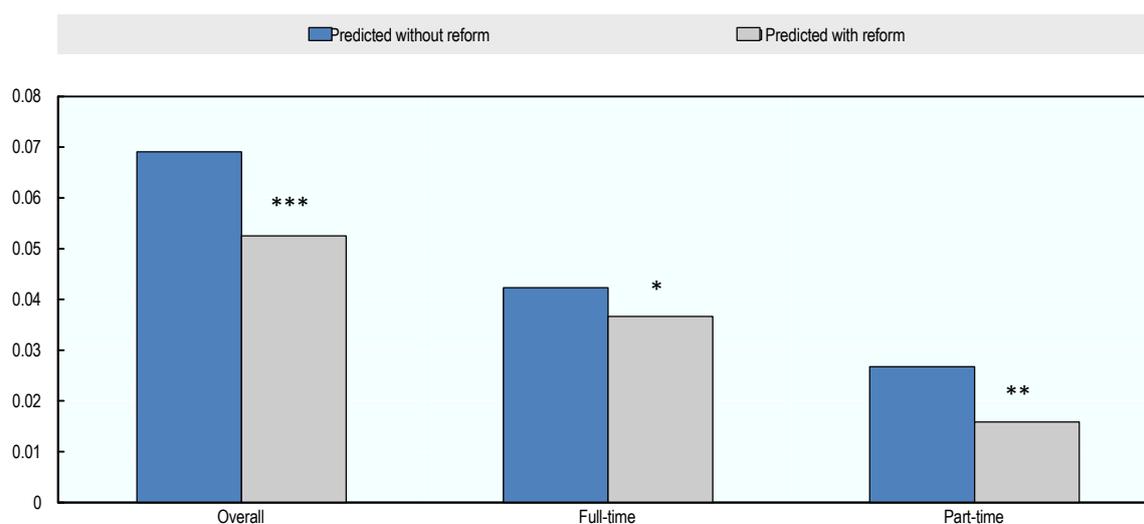

while the effect remains insignificant for those who previously held a permanent contract. Symmetrically, the results suggest a marginally positive impact of the reform on the speed of transition towards a temporary contract only for those that had a permanent contract prior to becoming unemployed. This is particularly good news insofar as it yields evidence of greater mobility across contract types, suggesting that the economy is on a slow path of a reduction of segmentation.

### Separation rates

The overall effect of the reform on worker separations is less obvious, as the reform eased firing procedures and reduced its costs but at the same time raised the incentives to adopt internal-flexibility measures, in the first place to avoid terminations. The *Encuesta de Coyuntura Laboral* (ECL) is a large establishment-level survey that registers worker flows at the establishment level and can, therefore, be used to shed light on which effect dominates.

The estimation results show that the 2012 reform significantly reduced the proportion of workers leaving the establishment in a given quarter. The average overall separation rate was reduced by 24% in the aftermath of the reform (Figure 13). The reduction has been particularly sizeable for the separation rate of part-time workers (41%) but there is also some evidence of an effect for full-time workers (13%), which however is only marginally significant from a statistical point of view.

Figure 13: The effect of the reform on quarterly separation rates at the establishment level

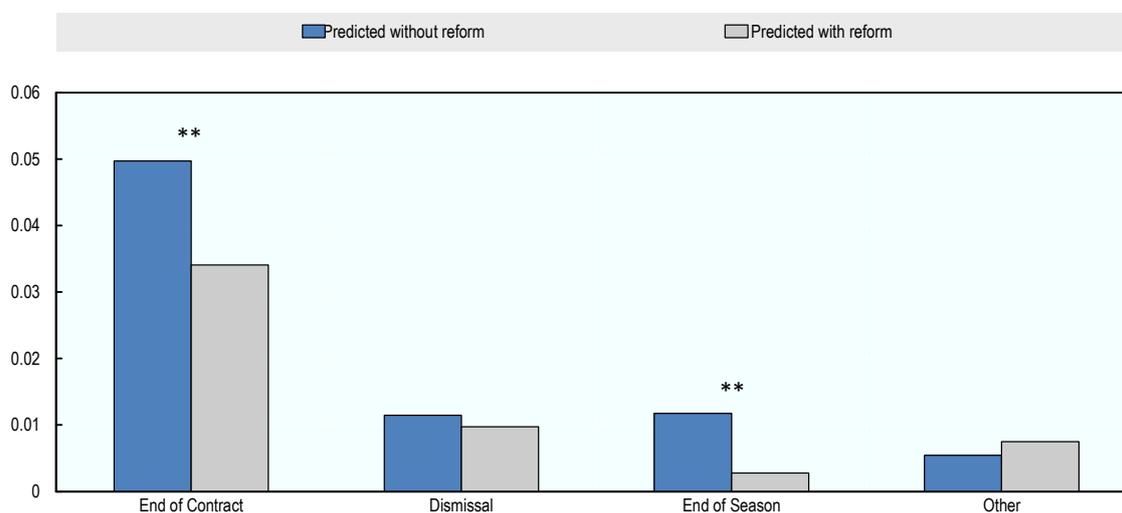

Note: The figure shows empirical estimates of average separation rates in the post-reform period obtained from the estimation on quarterly data for the period 2006-2012 of the baseline model of establishment-level separation rates, as predicted by observable variables. "Predicted without the reform" indicates the empirical predictions of what separation rates would have been in the absence of the reform. For each establishment, separation rates are defined as the ratio of separations in a quarter divided by the average of total employment between the start and the end of the period. The asterisks refer to the significance level of the estimated effect of the reform on each separation rate. \*\*\*, \*\*, \*: significant at the 1%, 5% and 10% level, respectively.

Source: Estimations on the basis of data from the Encuesta de Coyuntura Laboral (ECL). See Annex for the detailed estimation method and results.

In addition, establishment-level data allows disaggregating flows by contract type and reason of separation. In particular, it is possible to obtain distinct estimates of the effect of the reform on contract terminations (for temporary workers), dismissals of permanent workers, terminations due to end of season for seasonal workers with an open-ended contract – "*fijos discontinuos*" – and other reasons for separation (including retirements, voluntary separations, deaths, etc.). The estimation results (Figure 14) point to a

significant impact of the reform on separations rates due to the end of contract for temporary workers (31% decrease) and seasonal workers (71% decrease), but show no impact on dismissal rates and separations for other reasons.

Figure 14. The effect of the reform on separation rates at the establishment level by type

Note: The figure shows empirical estimates of average separation rates in the post-reform period obtained from the estimation on quarterly data for the period 2006-2012 of the baseline model of establishment-level separation rates, as predicted by observable variables. "Predicted without the reform" indicates the empirical predictions of what separation rates would have been in the absence of the reform. For each establishment, separation rates are defined as the ratio of separations in a quarter divided by the average of total employment between the start and the end of the period. The asterisks refer to the significance level of the estimated effect of the reform on each separation rate. \*\*: significant at the 5% level.

Source: Estimations on the basis of data from the Encuesta de Coyuntura Laboral (ECL). See Annex for the detailed estimation method and results.

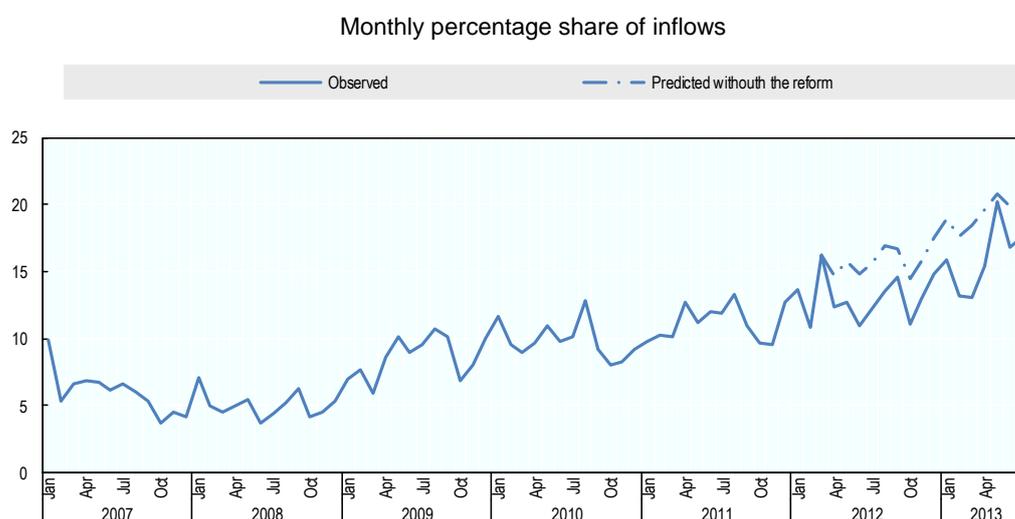

The analysis of job spells and reasons for termination using social security microdata (MCVL) appears to confirm the results for both dismissals and separations for other reasons obtained with establishment-level data. For permanent workers, the estimation results do not show any effect of the reform on the duration of job spells and the probability of separation, no matter whether for dismissal or for other reasons. However, as regards fixed-term contracts, no effect of the reform on contract duration and separation probabilities is found in MCVL data, in contrast with results obtained with establishment-level data. Even though simple statistical reasons might explain this discrepancy,<sup>39</sup> it suggests some caution in interpreting these findings. At the very least, however, these results seem to confirm that the reform has not increased the number of separations, in general, and dismissals, in particular. This fact suggests that the stimulus provided by the reform to internal flexibility measures as an alternative to job suppression more than compensated for the upwards effect on separations brought about by the easing of dismissal procedures and costs.

39. For example, there is some evidence that the reduction of termination rates for temporary contracts is concentrated in small establishments (see the Annex). As a consequence, the reform has reduced the average establishment-level separation rate with smaller or no impact on aggregate separations (insofar as aggregate separation rates can be seen as a weighted average of establishment-level ones, with establishment size as weight).

### Individual and collective dismissals

Has the distribution of dismissals – between individual and collective terminations – been affected by the reform? It is possible to resort to monthly statistics on inflows onto unemployment benefits (*prestaciones por desempleo*) to investigate the relative variation of individual and collective dismissals, insofar as the reason for claiming benefits is reported in these data.<sup>40</sup> The share of collective dismissals increased steadily since 2008, from about 5% to a peak of 20% in May 2013 (Figure 15). However, there is no sign that the reform is responsible for this trend: the share of inflows onto unemployment benefits due to collective dismissals seems to have been on the rise even before, probably as the result of the restructuring of the economy brought about by the economic crisis. On the contrary, the estimated results indicate that the share of collective dismissals would have been 3.1 percentage points larger in the absence of the reform. In practice, the empirical estimates suggest that the 2012 reform decreased the number of inflows onto unemployment benefits for reasons of collective dismissals by about 32%, while in the same period the contraction of inflows due to individual dismissals was small and marginally significant.<sup>41</sup>

Figure 15. Share of inflows onto unemployment benefits due to collective dismissal in total inflows due to dismissal, 2007-2013

Note: The figure presents the monthly percentage share of inflows in unemployment benefits due to collective dismissal in total inflows due to dismissal, as observed in raw data and as they would have been in the absence of the reform, according to baseline estimates on the basis of data covering the period January 2007-July 2013.

Source: Estimations on the basis of data on the *prestaciones por desempleo de nivel contributivo* (Source: MEYSS). See Annex for the detailed estimation method and results.

40. However, some cautions must be exerted in interpreting the results from this analysis since not all dismissals are counted. Inflows data considered here are limited to workers who are eligible to standard unemployment benefits because of sufficient previous contributions and contribution periods (*Prestaciones de nivel contributivo*). They exclude, therefore, workers only eligible for other types of unemployment-related subsidies (*Prestaciones de nivel asistencial*). Moreover, inflows data considered here exclude those resulting from conciliation settlements, court rulings, end of trial period or contract suspensions, because the nature of the originating event (individual or collective dismissal) is not reported. By contrast, benefit claims ex *Ley 45/2002* – individual dismissals for which benefits are claimed before any court ruling stating whether the dismissal is fair or unfair – are included in the analysis.
41. In the baseline model, the estimated contraction for these inflows is of 6%. However this estimate is significant at the 10% level only and is not robust to changes in the specification (see the Annex for more details).

Taking into account the discussion of Section 2.2, these findings are probably not surprising. There is little controversy that the 2012 reform reduced the cost and difficulty of individual dismissals, which explains the pick-up on hiring on permanent contracts that has been observed since its implementation (see above). As already noted, the lack of impact of the reform on individual dismissals is likely to be due to the counterbalancing effects of greater use of internal flexibility measures and lower cost of individual dismissals. By contrast, the case of collective dismissals is more complex. On the one hand, the reform has made economic dismissals significantly easier, even though this is true for both individual and collective dismissals. On the other hand, the reform, under certain circumstances, has increased the taxes levied on firms in the case of collective dismissals (see section 1). Moreover, the reform, as implemented initially, significantly increased the risk that the dismissal procedure could be invalidated by a court in the case of litigation. The observed empirical patterns tentatively suggest that these factors are likely to have played a key role in discouraging collective dismissal decisions.<sup>42</sup> Yet, to the extent that the *Real Decreto Ley 11/2013* approved in August 2013 has restricted the discretionary role of courts of declaring a dismissal void and ordering reinstatement (see Section 1), it would not be surprising if some of the negative effects of the 2012 reform on the share of collective dismissals in total dismissals are subsequently unwound.

#### *Firm-size differences in the impact of the 2012 reform*

Given the importance of the provisions targeted at small firms in the architecture of the reform (see Section 1), it is important to evaluate firm-size differences in its impact. In Spain, employers have the obligation to inform the public employment service about the characteristics of all new individual contracts they sign as well as about extensions of fixed-term contracts and/or their conversions into permanent contracts. These data are then collected into a database – containing also workers and employers characteristics, including firm size – that can be used to analyse the dynamics of new contracts on a monthly basis, allowing the examination of firm-size heterogeneity in hiring patterns.

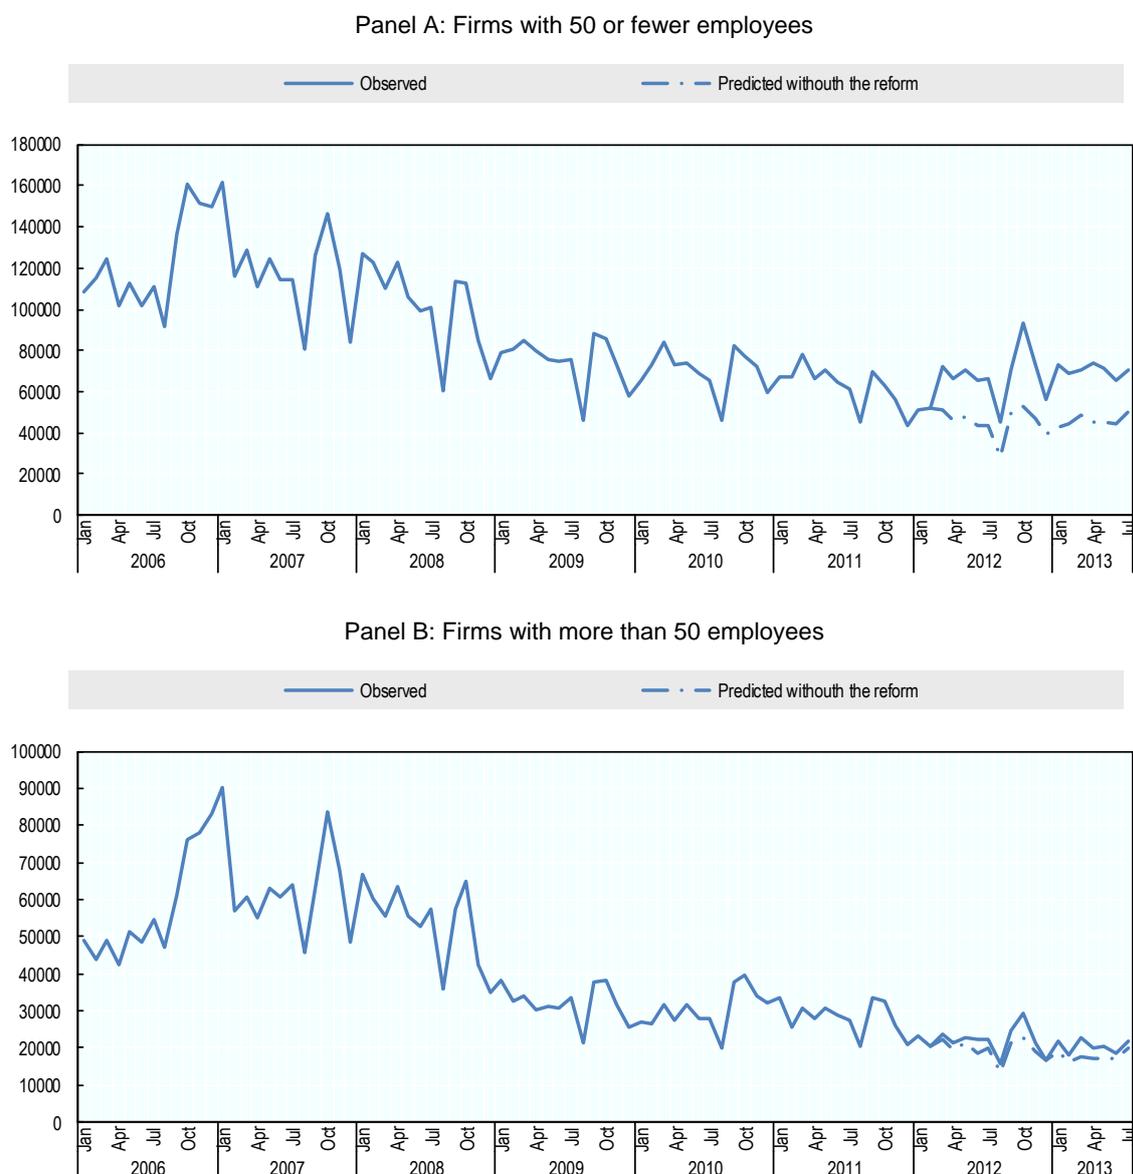

In January 2007, about 250,000 new permanent contracts were signed (Figure 16). Of these, about two-thirds were in firms with 50 or fewer employees (cf. Panel A and B). As already noted, the crisis hit job creation hard. Five years later, new permanent contracts were as few as 75,000 per month, with the proportion accounted by small firms remaining approximately constant. The trends concerning new open-ended contracts by firm size has diverged since then. For example, in January 2013, firms with 50 employees or less accounted for more than three-fourths of all new permanent contracts concluded that month.

To what extent are these developments accounted for by the 2012 reform? The econometric models estimated for this report suggest that at least 25 000 new permanent contracts per month in firms with 50 employees or less can be attributed to the 2012 reform, while no significant effect is observable for larger firms. These patterns are mirrored by those of the share of permanent contracts in all new contracts, which is estimated to have been raised by 3 percentage points – that is a percentage increase of about 30% – for firms with 50 or fewer employees.

---

42. However, as discussed in Section 1, individual dismissals have become particularly easier and less costly in the case of small firms: companies with less than 50 employees can hire by stipulating an open-ended *contrato emprendedores*, which allows a trial period of up to one year, while companies with less than 25 employees can apply for a severance-pay subsidy for any type of fair dismissal. It is not impossible that part of the effect of the reform on the share on collective dismissals can be attributed to these provisions targeted at small firms. As benefit inflows disaggregated by firm size are not available, this issue cannot be investigated further here. Firm size heterogeneity in the impact of the reform is examined in the next subsection as regards other types of flows.

Figure 16. Monthly inflows into permanent contracts, including contract conversions, 2006-2013

Note: The figure presents the number of new permanent contracts signed each month, as observed in raw data and as they would have been in the absence of the reform, according to baseline estimates covering the period January 2006-July 2013.

Source: Estimations on the basis of data on the *datos estadísticos de contratos* (Source: SEPE). See Annex for the detailed estimation method and results.

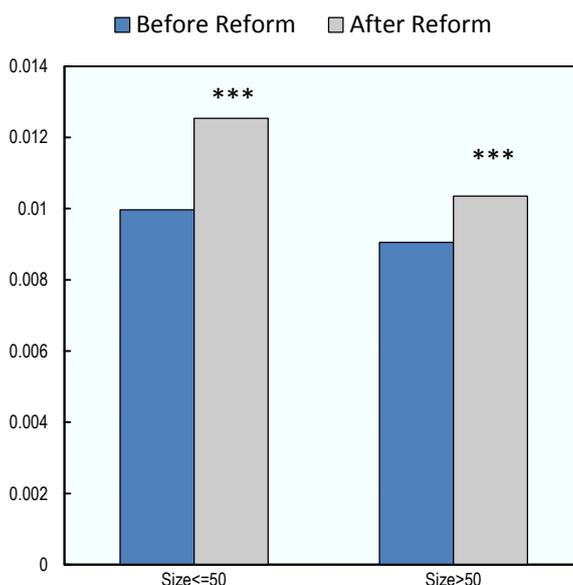

Consistently, it appears from the analysis of social security microdata that the 2012 reform had a greater impact on transitions from unemployment to permanent employment in small establishments rather than large establishments (Figure 17).<sup>43</sup> The results from the estimation of the competing-risk hazard

43. Although a disaggregation by firm rather than establishment size would be more interesting, this is not possible given the available data. The only size variable which is available in the *Muestra Continua de Vidas Laborales* is the size of the social security accounting unit (*Cuenta de Cotización*), which is unique for each firm at the provincial level. It does not correspond exactly either to the plant or the firm level – it covers many plants of the same firm if they are in the same province but plants established in different

models suggest that the reform increased the average transition to a permanent contract – conditional on being unemployed for six months or less – by 26% in establishments with 50 or fewer employees, compared with 15% in establishments with over 50 employees. To the extent that the large majority of firms are mono-establishments, this confirms that the impact of the reform on hiring is greater for smaller firms.

Figure 17. **Exit from unemployment to permanent employment by firm size**

Monthly probability of individual transition for unemployment durations smaller or equal than 6 months

*Note:* The figure presents the average of estimated monthly probabilities of individual transition from unemployment to permanent employment just before (February 2012) and after (March 2012) the reform conditional on being unemployed at least one day but less or equal than 6 months, by type of contract and firm size. Unemployment durations are censored at 30 months in unemployment. The asterisks refer to the significance level of the estimated effect of the reform on each transition probability. \*\*\*: significant at the 1% level.

*Source:* Estimations on the basis of data from the Muestra Continua de Vidas Laborales (MCVL). See Annex for the detailed estimation method and results.

When the data are further disaggregated by firm size, the greatest estimated expansion in the number of new permanent contracts induced by the reform is found in very small firms with 25 employees or less (45%, corresponding to about 21,000 new contracts per month). By contrast, in firms with 26 to 50 employees the increase was relatively more modest, not only in absolute terms (about 4,000 new contracts per month) but also in percentage terms (about 28%).

Given that the positive effect of the reform appears concentrated in very small firms, a first obvious candidate in explaining these findings is the severance-pay subsidy made available for firms with less than 25 employees in all cases of fair dismissal (see Section 1). Indeed, to the extent that fair economic dismissals have become easier and less uncertain after the reform, this subsidy is likely to play a greater role than before the 2012 reform, when most employers used to take the route of “*despido expreso*” and severance payments were therefore not subsidised. Obviously, however, this provision alone cannot explain the significant impact for larger companies. Another factor that is likely to be behind this upsurge

---

provinces are not linked. For a matter of simplicity each social security accounting unit is referred to as an “establishment”, hereafter.

in hiring on permanent contract is the introduction of the *contrato emprendedores*, which *de facto* extended the trial period for firms with less than 50 employees.<sup>44</sup> Indeed, for these firms, the positive effect of the reform is somewhat larger on new hires than on contract conversions, which in the period of analysis concerned, by and large, correspond to workers hired before the reform. Yet, some significant impact of the reform is detectable in the case of conversions as well.

Can these two factors, taken together, fully explain the firm-size heterogeneity of the effect of the reform? This is far from clear. Less than 8,000 *contrato emprendedores* are typically stipulated in a representative month. Given that the number of new permanent contracts in firms with 25 or fewer employees is on average 5 times larger than the corresponding figure for employers with 26 to 50 employees, a large share of the new *contrato emprendedores* is likely to have been signed in firms with 25 or fewer employees.<sup>45</sup> Moreover, in firms with 26 to 50 employees, the impact of the reform on contract conversions is very close to that on new hires on permanent contract. These observations suggest a third factor that could be behind the observed empirical patterns. The larger the size of the firm, the greater the likelihood the firm needs to undertake a large number of dismissals at some point in time. But the threshold triggering collective dismissal procedures varies little with firm size (from 10 dismissals within a period of 3 months for firms with less than 100 employees to 30 employees within the same period for firms with 300 employees or more); therefore, collective dismissals procedures are likely to be more often binding in the case of larger firms.<sup>46</sup> Given that the evidence presented in the previous subsection and in Section 2.2 suggests that collective dismissals might not have become less difficult and costly, larger firms might have refrained from hiring on permanent contracts to avoid incurring the risk of making collective dismissals in the future, particularly at a time of sluggish demand and uncertain perspectives.

This conjecture can be tested by examining further by more disaggregated size classes the impact of the 2012 reform on hiring by firms with more than 50 employees. The estimated results based on contract data show that the reform has significantly increased the number of new permanent contracts in firms with 51 to 100 employees (by 23%), while no significant effect is detected for larger firms.<sup>47</sup> To the extent that all these firms are ineligible both for the *contrato emprendedores* and for the severance-pay subsidy, the combination of easier individual dismissals and more burdensome collective dismissals remains the only explanation for the simultaneous increase in the number of permanent contracts stipulated by firms with 51 to 100 employees and the lack of significant changes for larger firms. Moreover, for the former class of firms, the positive effect of the reform is entirely concentrated in contract conversions, suggesting that these firms use fixed-term contracts as a substitute for longer trial periods.

Overall the evidence presented in this section not only suggests that the Spanish labour market has become more dynamic in the aftermath of the 2012 reform but also that duality is decreasing. Indeed, hiring on permanent contracts is on the rise while there is no evidence of an increase of transitions out of permanent contracts. The latter fact is also confirmed by recent evidence provided by the Ministerio de Empleo y Seguridad Social (2013), which shows that there is no difference in the probability of leaving a

---

44. This could also contribute to explain why the effect is concentrated in very small firms: to the extent that mismatching problems are likely to be more problematic in these firms, they can benefit more from the longer trial period made available by the *contrato emprendedores*.

45. No breakdown by firm size is available for the *contrato emprendedores*.

46. For example, according to OECD (2009) the average quarterly dismissal rate of continental European countries for which data are available is close to 1%. That is, in a normal year, almost 1% of employees are dismissed each quarter. Therefore, any firm with 3,000 employees or more dismissing at that rate would cross the threshold defining collective dismissals.

47. The difference between these two classes of firms in the effects of the reform is also significant, at least at the 10% level.

permanent contract conditional on tenure between a *contrato emprendedores* and a standard open-ended contract in the first 12 months of a job spell. This implies that longer trial periods in the former type of contract have not implied greater precariousness for workers hired with these contracts. Moreover, dynamic segmentation has also been reduced insofar as transitions between temporary and permanent contracts have become more frequent (see above). Nevertheless, if the percentage increase of transition rates that can be attributed to the reform is sizeable, their absolute magnitude is small. Moreover, there is some evidence suggesting that the reform have particularly reduced separations for temporary contracts, due to the greater incentives for internal flexibility as an alternative to the suppression of fixed-term posts (see Figure 14). As a consequence, it is likely that it will take some time before these developments become visible in the share of temporary employees in total employment. Indeed, using the same microeconomic model used before for hiring rates but replacing the dependent variable, no significant effect on the share of workers with a fixed-term contract is estimated if the regression discontinuity is set at the time of the reform (first quarter of 2012),<sup>48</sup> while a modest – albeit robust and significant – effect appears if the discontinuity is tested one year later.<sup>49</sup> It is, however, too early to say what will be the magnitude of the long-run impact of the reform on this variable.

### 3.3. *Simulating the long-run impact of the 2012 reform on productivity and economic growth*

The increase in the pace of reallocation of labour resources and the reduction in labour market duality are expected to increase efficiency and labour productivity growth in the long term (see Section 2.2). However, insofar as multi-factor productivity growth – measuring efficiency enhancement in an economy – cannot be meaningfully estimated at greater frequencies than annual ones, it is not possible to test whether the 2012 reform has effectively brought about this outcome. Nevertheless, by exploiting the quantification of the institutional change implied by the reform – as reflected in OECD EPL indicators – and resorting to estimates available in the literature, it is possible to provide a tentative estimate of the potential impact of the 2012 reform on productivity growth and, with some additional assumptions, overall economic growth.

Bassanini et al. (2009) estimate the long-run potential impact of changes in the OECD summary indicator of EPL for regular contracts (see Section 2.2) on multi-factor and labour productivity growth in the business sector, excluding agriculture, mining, fuel and professional services.<sup>50</sup> Their industry-specific estimates are based on the characteristics of each industry, notably as regards the propensity to use dismissals as a way to adjust to shocks.<sup>51</sup> Taking their most reliable estimate at face value and assuming as given the sectoral structure of the Spanish economy in 2007,<sup>52</sup> in the long-run an hypothetical reform reducing the EPL indicator for individual and collective dismissals by half a point – a large reform in terms of the historical record for OECD countries –<sup>53</sup> would result, in the business sector, in higher multi-factor

48. This finding is confirmed by running the same estimation model on social security data.

49. The estimated drop of the share of temporary workers is of 0.5 percentage points.

50. These industries were excluded due to the difficulty of measuring accurately multi-factor productivity growth therein.

51. This propensity is approximated by industry-specific US dismissal rates, a choice justified by the light firing regulations in this country that can be then taken as a benchmark to mimic the distribution of dismissal rates in the absence of regulation.

52. This year is chosen to avoid that the simulation be perturbed by large cyclical swings in the structure of the economy. Results are however robust to the choice of the year.

53. The 2003 severance-pay reform in Austria, often cited as an example of large, radical reform, resulted in about half a point reduction of these indicators.

annual productivity growth by 0.45 percentage points and faster labour productivity growth by 0.3 percentage points.

What predictions would these estimates imply for the Spanish economy? The size of the 2012 reform, as measured by OECD indicators, is only slightly smaller (0.44; cf. Figure 4) than what considered by Bassanini et al. (2009). By applying the same estimated coefficients, it can be expected that, in the long-run, labour productivity should grow faster by about  $\frac{1}{4}$  of a percentage point each year in the business sector (excluding agriculture, mining, fuel and professional services) as the result of the reform. Taking into account that these industries accounted for 59% of total value added in the Spanish economy before the crisis, and assuming conservatively no impact on employment and productivity in other industries, this would translate into 0.15 faster GDP growth each year. This number can be seen as very rough lower-bound estimate, to the extent that it is based on the assumption of no impact on other industries and no impact on employment. While the latter assumption would be reasonable had the reform been limited to employment protection, the wage moderation induced by the reform of collective bargaining is likely to result in greater employment growth, thereby raising GDP growth even further.

#### 4. Interactions with other policies

The previous section has assessed the impact of the 2012 reform of Spain's labour market legislation as has occurred so far. However, these reforms should be considered and evaluated in the broader context of structural reforms and policies in other areas. Indeed, as suggested by the *Revised OECD Jobs Strategy* (OECD, 2006), the effects of macroeconomic and structural policies are strongly interdependent and institutions should be designed and reformed in such a way to exploit their complementarity. In other words, the full materialisation of the positive employment impact of the recent labour market reform is strictly conditional on complementary reforms in other areas.

First of all, macroeconomic conditions affect overall labour market performance and the effect of the 2012 reform will depend on any macroeconomic shocks the Spanish economy might suffer. Sound macroeconomic policies are necessary to support economic and employment growth. In that respect, it is important to keep the public debt on a sustainable path, while carefully avoiding excessively restrictive fiscal stances. The pension reform proposed by the government, following the recommendations of a commission of experts, would go in this direction, as it would ensure the long-term sustainability of the pension system as well as intergenerational solidarity. Indeed the reform proposal would envisage coupling, by 2019, the introduction of a revalorisation index (*Índice de Revalorización de las Pensiones*) – guaranteeing the adjustment of pensions only conditionally on the favourable evolution of a large number of parameters – with that of a sustainability factor (*Factor de Sostenibilidad*) – linking the amount of the retirement pension to changes in life expectancy (see e.g. BBVA, 2013a).

In addition, numerous interactions exist between labour legislation and product market institutions. Reforms in the product and service markets will not only increase competition and boost productivity, but they will also have an impact on labour market performance (Blanchard and Giavazzi, 2003, Nicoletti and Scarpetta, 2005). Spain has already undertaken several reforms in 2012 and 2013 (e.g. *Programa Nacional de Reformas 2013* and the update of the Stability Program Update for Spain 2013-2016). However, it is not yet clear to what extent the fall in unit labour costs (see Section 3.1) translates into a commensurable fall of price inflation<sup>54</sup>, thereby guaranteeing a full impact of wage moderation on competitiveness. To avoid that slower wage growth results only in higher profits, without raising competitiveness, a further push on

54. For example, the average increase in wages as set in collective agreements in 2012 was 1.3% (0.9% in new collective agreements), while inflation was 2.9% (Izquierdo et al., 2013), a relative high level in comparison with Eurozone competitors. However figures for 2013 suggest that inflation is declining significantly and is now close to 0.

product and service market competition might be necessary (European Commission, 2013). Estimates by Bassanini and Duval (2009) suggest that the effect on unemployment of simultaneous reforms of anti-competitive product market regulations and industrial-relation institutions – such as the reform of collective bargaining discussed in Section 3.1 – is at least 15% larger than the sum of the effects of the two policy reforms taken in isolation.

The reform of the financial sector is currently underway and remains on track (IMF, 2013). Nevertheless, debt levels remain high and constrain the private sector's ability to borrow (La Caixa, 2013). Available evidence from other countries suggests that falling bank lending dramatically affects investment of small and medium enterprises, making their employment level slump. For example, Chodorow-Reich (2014) finds that the withdrawal of credit accounted for between one-third and one-half of the employment decline in US small and medium firms in the year following the Lehman bankruptcy. Similarly, using Italian data, Cingano et al. (2013) find that a 10 percentage-point fall in credit growth reduces the investment rate by 8-14 percentage points over four years, and employment by almost 1.5%. Restoring the health of the financial markets and easing the credit crunch is particularly important in the case of Spain, given the large share of small firms in this economy.

Another essential element to improve the functioning of the Spanish labour market and reviving employment creation relate to active labour market policies. In Spain, the administration of unemployment benefit system depends on the Spanish public employment service (SEPE) in the central government, while the development of active labour market policies is done by the regional governments (following the legislative framework approved by the central government).

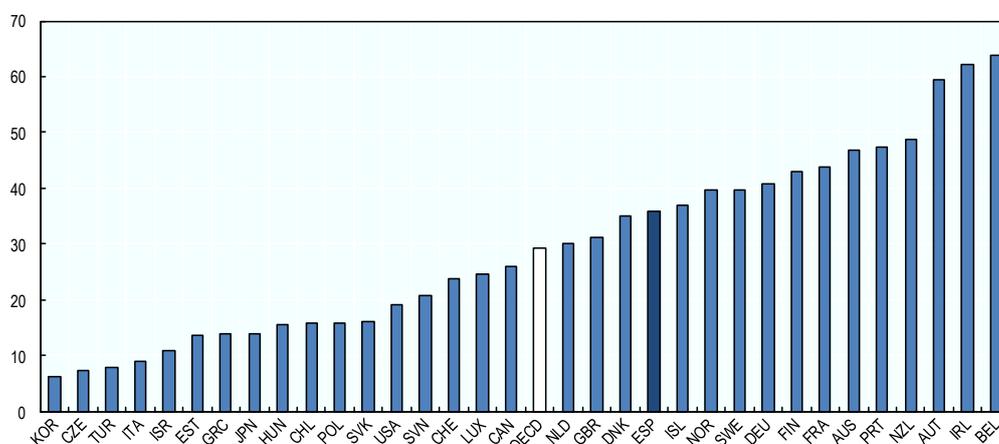

The Spanish unemployment insurance is relatively generous with respect to the OECD average (Figure 18). Providing adequate unemployment benefits can be desirable in the context of significant structural reforms: while many workers are likely to gain from these reforms, certain groups of workers would inevitably lose their jobs in their aftermath and require support to regain employment. However unemployment benefits must be made conditional on strictly-enforced work-availability conditions and included in a well-designed “activation” package. The decentralized public employment service may not have the capacity for implementing activation policies on a sufficient scale to counterbalance the potential negative effects of generous benefits on work incentives. Spain's expenditure on passive measures is around 3% of GDP (the highest level in the OECD), while expenditure on active measures is slightly below 1%,<sup>55</sup> and most of the “active” expenditures are employment incentives. More important, the plurality of actors in this area makes it difficult to integrate properly-enforced job-search requirements and effective re-employment services with the provision of adequate unemployment benefits. Last but not least, resources for preventing the receipt of benefits when in undeclared employment have always been limited in Spain.

Since the start of the recession, there has been a movement along the Beveridge curve (Figure 19), which allows identifying changes in the efficiency of the process of matching unemployed workers to vacancies – an inward shift of the curve representing an improvement in matching efficiency. The figure shows a decrease in the vacancy rate paralleled by an increase in unemployment, corresponding to the increase in labour market slack. Yet, no inward shift of the curve is detectable since the 2012 labour market reform, suggesting that inefficient activation policies are hampering the improvement in matching efficiency. In the most recent quarters, there seems to be even an outward shift denoting intensification in matching frictions, although probably due only to the simultaneous increase in long-term unemployment and the renewed firms' propensity to post vacancies (see Section 3.2).

55. Even if part of the low ratio between active and passive expenditures is due to the recession.

Figure 18. Average of net replacement rates over the first 60 months of unemployment, 2011

Unweighted average of two income levels and four family situations, excluding social assistance

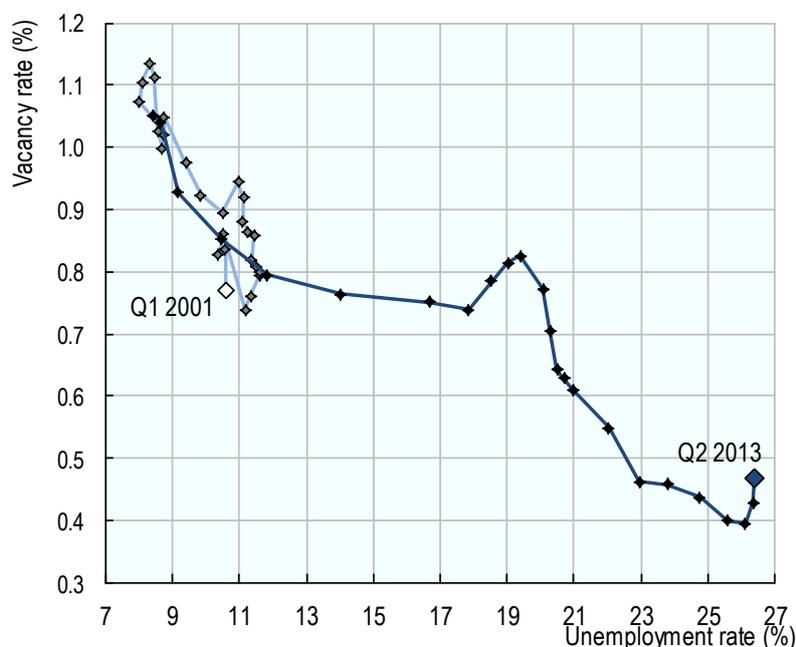

Note: Unweighted averages, for full-time earnings levels of 67% and 100% of the average wage (AW) and four family situations (single persons, couple, with two children and without). Family benefits are included. Any income taxes payable on unemployment benefits are determined in relation to annualised benefit values (i.e. monthly values multiplied by 12) even if the maximum benefit duration is shorter than 12 months. For married couples the percentage of AW relates to the previous earnings of the "unemployed" spouse only; the second spouse is assumed to be "inactive" with no earnings and no recent employment history. Children are aged four and six and neither childcare benefits nor childcare costs are considered.

Vacancy and unemployment rates as a percentage of the labour force, Q1 2001-Q2 2013

Note: Job vacancy rates refer to the non-agricultural sector. The light blue line corresponds to the period up to 2007 Q4, while the dark blue line corresponds to the period since 2007 Q4.

Source: OECD calculations based on OECD Short-Term Labour Market Statistics Database and Eurostat, Job Vacancy Statistics.

Some improvements have taken place in the domain of activation policies. The strategy for entrepreneurship and youth employment 2013-2016 (*Estrategia de Emprendimiento y el Empleo Joven 2013-2016*) approved in February 2013<sup>56</sup> includes measures to encourage youth employment, facilitating job-placement in salaried employment as well as the start of entrepreneurship activities. For example, among the measures approved so far, new hiring incentives to employ unemployed youth have been created and a reduced flat rate for social security contributions for young entrepreneurs has been introduced. Moreover, the annual coordination mechanism between central and regional governments (*Plan anual de política de empleo 2013*)<sup>57</sup> approved in August 2013 has introduced several changes to improve the coordination between national and regional administrations. This agreement states the annual objectives of employment policies in Spain and introduces several evaluation measures of the activities performed by the regional governments. Up to 40% of the funding of active labour market policies of regional governments will be conditional on those evaluation measures. In addition, since August 2013, an individual needs to be registered as unemployed in the regional office and keep this status in order to receive and maintain the right to receive unemployment benefits.

The changes introduced in the domain of active labour market policies go in the right direction, but it remains to be seen whether they are sufficient to be effective, in particular insofar as they fall short of fully integrating active and passive policies. In the context of a prolonged recession, it is very important to focus on improving activation policies to help those unemployed to find jobs. For this, it is crucial to have the right institutional setting with effective employment services. Further in-depth analysis would be required in order to identify the possible weaknesses in the current Spanish system in the delivery and provision of income support and employment services. In particular, it will be important to ensure transparency in the monitoring of the effectiveness of regional active labour market programmes and that there are strong incentives at the local level to follow best practice. This is the case in Switzerland, for example, where cantons work under very clear guidelines and are subject to close scrutiny by the central government (see e.g. Düll et al., 2010, OECD, 2013a).

## 5. Conclusions and recommendations

The 2012 labour market reform in Spain appears to have been a significant step in the right direction. As the result of it, the Spanish labour market has already shown some signs of increased dynamism and this is likely to bring about lower dualism and faster productivity growth in the medium term. The reform focused primarily on collective bargaining and on dismissal regulations. This report provides a very preliminary assessment of the short-run effects of the reform on labour market performance. This is an important caveat insofar as: i) only a short period has elapsed since the implementation of the reform; ii) Spain is only now showing timid signs of recovery from a long recession; and iii) due to the breadth of the reform, it is difficult to clearly identify a counterfactual to carry out a standard evaluation. As a consequence, further monitoring is required to fully assess the impact of the reform in the medium and long term.

The analysis presented here confirms that, as suggested elsewhere (e.g. Izquierdo *et al.* 2013, Ministerio de Empleo y Seguridad Social, 2013, BBVA, 2013a), the effect of the reform on internal flexibility and collective bargaining has played an important role in the recent contraction of unit labour costs, although protracted adverse cyclical conditions are not alien to this pattern. It is not yet possible to say whether the reform will restore competitiveness over the medium to long term. However, the Spanish economy appears to have made progress in achieving wage moderation, which allows setting jobs in times of crisis, even if continuous monitoring of the effect of the reform in this area is advisable, and the

56. *Real Decreto-ley 4/2013*, full legislative text available at <http://www.boe.es/boe/dias/2013/02/23/pdfs/BOE-A-2013-2030.pdf>.

57. The full legislative text is available at <http://www.boe.es/boe/dias/2013/09/10/pdfs/BOE-A-2013-9464.pdf>.

government must be ready to implement further action if performance worsens. In addition, trends in income inequality should be monitored in order to guarantee that the costs and benefits of the reform are equally shared.

The analysis also shows an effect of the reform on hiring, particularly on permanent contracts, which is most likely the outcome of the relaxation of dismissal regulations. Consistently, the reform appears to have also reduced the duration of unemployment spells, essentially due to faster transitions towards a permanent contract. In addition, there are signs of a fall in the segmentation of the labour market insofar as transitions to permanent jobs have increased in particular for workers entering unemployment after a temporary contract. There is also some evidence of a reduction in separations, particularly for temporary workers, possibly resulting from the application of internal flexibility measures as an alternative to contract termination. Nonetheless, there is also evidence of a negative effect of the reform on collective dismissals, probably due to the increase in procedural uncertainty that initially followed the elimination of the administrative authorisation as well as the increase in the relative direct costs of collective dismissals with respect to individual terminations. In this respect, the government was quick to react with a mini-reform in August 2013 to reduce this uncertainty. It is too early to say whether this intervention will prove sufficient to restore outcome predictability. Yet, the discretionary role of courts to invalidate a collective-dismissal procedure and order reinstatement of workers with backpay remains large, at least on paper.

The increase of new permanent jobs is concentrated in small and medium sized employers, despite the persistent credit crunch, which is likely to affect especially this class of firms, insofar as they are more reliant on bank lending than on equity finance or corporate bonds. The greater burden on collective dismissals can be considered as one of the factors that explain why no increase in hiring is observed for large firms. Nonetheless, two other elements appear to have played a key role in determining the faster growth of open-ended contracts in small firms: i) the extension of the trial period for firms with less than 50 employees, made possible by the introduction of the *contrato de Apoyo a emprendedores*; and ii) the severance-pay subsidy, made available to firms with less than 25 employees in all cases of fair dismissal. The latter is likely to play a greater role after the 2012 reform, insofar as fair economic dismissals have become easier.

The results of the empirical analysis suggest that the reform could have contributed to 25 000 additional new permanent contracts each month and increased the share of permanent jobs in new hires by 3 percentage points. However, the share of temporary contracts in new contracts remains high. Moreover, there is some evidence that incentives to internal flexibility measures have particularly contributed to save the jobs of workers on fixed-term contracts. Thus, these pieces of evidence suggest that it may take some time before these new patterns have a visible impact on the proportion of fixed-term employees in total employment.

Whether or not the 2012 labour reform is sufficient to transform the Spanish labour market into one that combines flexibility with fairness and worker security remains to be seen. Nevertheless, to improve the likelihood that this objective will be attained, the empirical findings presented in this report suggest that further adjustments might be desirable and could be put in place at little social cost.

- First, given the evidence presented in this report, some action as regards regulation for collective dismissals could be taken. Even though it cannot be established whether the August 2013 revision is sufficient to rebalance incentives, a cautious approach would suggest reducing further the discretionary role of courts to invalidate dismissals, restricting it only to cases of discrimination and prohibited grounds – as in the case of individual terminations. In this way, unlawful collective dismissals will be treated – as in most other OECD countries – as any other type of unfair dismissal, thereby restoring the equilibrium between individual and collective dismissals. Moreover, some of the additional, specific costs for employers in the case of

collective dismissals introduced by the reform could be rolled back, notably those contributions linked to the firm's future profitability, which increase uncertainty at the time of starting the dismissal procedure about the effective financial burden to be borne by employers.

- Second, there is evidence that the trial period is still too short for most firms that are not eligible for the *contrato emprendedores*. Firms with 50 to 100 employees, not eligible for this type of contract, have increased their share of permanent contracts since the 2012 reform. However, this increase is entirely due to contract conversions, showing that these employers still tend to use fixed-term contracts as a surrogate for longer trial periods in order to screen new recruits. To the extent that dismissing non-performing or mismatched employees after the expiration of the trial period remains difficult in Spain, the government could therefore consider lengthening the maximum duration of trial periods up to at least the OECD average for firms not covered by the *contrato emprendedores*, particularly in those cases in which this duration is currently much shorter.
- Third, a greater convergence of employers' costs of termination for permanent and temporary contracts would be desirable. This will be already the case by 2015 for firms with less than 25 employees – for fair terminations – due to the severance-pay subsidy in place for these firms and the schedule of increases in severance pay for fixed-term contracts approved in 2010. By that date, for firms within this size class, severance costs borne by the employer for fair terminations at its own initiative will be equalised, no matter whether the contract is open-ended or fixed-term. The government could consider deepening this convergence process by reducing severance pay, and in particular ordinary severance costs for large employers.
- Last but not least, greater integration of active and passive policies is required in order to increase the capacity of the Spanish economy of matching the unemployed with vacancies. In this respect, a careful evaluation of recent reforms in this area is required. In particular, it will be important to ensure transparency in monitoring the effectiveness of regional active labour market programmes and that there are strong incentives to follow best practice. In addition, the introduction of a *Youth Guarantee* scheme as recommended by the European Council earlier this year for all EU countries would also be a welcome step to reduce unemployment and NEET (not in employment or education and training) rates among youth. But this will require ensuring that cost-effective public and private employment services are in place to roll out the guarantee while maintaining a high level of services for all job seekers.

## ANNEX

### EMPIRICAL FRAMEWORK AND DETAILED ESTIMATION RESULTS

The evaluation of the 2012 Spanish labour market reform is an arduous task. First, the exercise is performed shortly after the reform. Available data cover at best 18 months in the post-reform period, but sometimes much less. Second, the inclusion of a large number of provisions, sometimes explicitly targeted at different groups, does not allow the identification of a control group. Third, the reform also occurred in the middle of a double-dip recession, at a time when the economic juncture restarted to deteriorate after a short recovery that was so hesitant that never stopped employment levels from falling. This suggests that one of the few available methods to analyse the role of the reform in the recent evolution of the Spanish labour market is through regression-discontinuity models in which the effect of the reform is identified through discontinuous patterns occurring at the time of its enforcement and the business-cycle is modelled through observable controls and non-linear time trends.

The estimation strategy followed in this report identifies the joint effect of all the provisions included in the reform by comparing labour market performance before and after February 2012. The key identification assumption is that, conditional on control variables included in the model, labour market performance evolves in a relatively smooth way, so that any discontinuous jump in performance (conditional on control variables) can be attributed to the labour market reform (and other institutional changes occurring simultaneously). The general regression-discontinuity model, which is estimated on various sets of either quarterly or monthly data, can be written as:

$$P_{it} = Y_i\beta + X_{it}\gamma + \delta I_{t>R} + \sum_{s=1}^5 \lambda_s (t-R)^s + \sum_{s=1}^5 \mu_s I_{t>R} (t-R)^s + D_t + \varepsilon_t \quad (1)$$

where  $P$  is a performance variable which can be measured at time  $t$  either at the aggregate level or at a more disaggregate level, indexed by  $i$  (such as the industry, the establishment or the individual level).  $Y$  and  $X$  are vectors of aggregate and disaggregate (if relevant) confounding factors, respectively, notably capturing composition effects, while  $R$  is the date of the reform,<sup>58</sup>  $I$  is the indicator function (which, in eq. (1) indicates the post-reform dummy),  $D$  stands for seasonal (e.g. quarterly or monthly) dummies, and Greek letters stand for parameters to be estimated, except for  $\varepsilon$ , which represents a standard error term. The parameter of interest is  $\delta$ . A significant estimate for this parameter suggests a significant impact of the reform. As suggested by Card and Lee (2008), since the identification is based on a time discontinuity, standard errors are always adjusted for clustering at least on time (and, where relevant, also on other dimensions). Moreover, probability weights are also used in order to ensure the relevance of results for the dynamics of the aggregate business sector.

Given the lack of control group and the particular time at which the reform took place (see above), properly isolating the effect of the reform from that of the business-cycle is key for the validity of the smoothness assumption. In order to capture economic fluctuations, the baseline estimation models control for the standardised unemployment rate, changes in employment registered with the general social security regime (at the regional or industry level when microdata are used) and, most importantly, polynomial time trends up to the 5<sup>th</sup> order. Baseline specifications include a polynomial trend up to the highest order  $n$  such

58. As the reform entered into force on February 12<sup>th</sup>, 2012,  $R$  is set at the beginning of 2012 in baseline specifications with quarterly data and at the beginning of March 2012 in those on monthly data (except if differently specified).

that the  $n$ -th term is not insignificant. However, except when specified otherwise, the results are robust both to changes in the order of the polynomial and to its exclusion from the specification. When a sufficiently long number of periods is available after the reform, polynomial trends are alternatively included as either homogeneous (same parameters before and after the reform) or heterogeneous (different parameters before and after the reform), the latter represented by the interaction term between  $I$  and the time trend in eq. (1). As a robustness check, employment changes are replaced with other – perhaps less endogenous – controls for the business cycle, such as changes in either industry-level value added or industry-level productivity growth (from quarterly national accounts) or the aggregate FEDEA index of economic activity. The FEDEA index is an indicator of economic activity in Spain that measures the economic cycle by using different sources of relevant information (GDP, Economic Sentiment Indicator, industrial production, car sales, electricity consumption and workers affiliated in social security)<sup>59</sup>.

Obviously, misspecification of the empirical model might lead to identify a discontinuous shift in performance around the date of a reform even when this shift occurs before the reform (and cannot therefore be attributed to it). To validate the empirical model, therefore, placebo tests need to be run. These tests consist in setting in the empirical model an earlier date than the actual reform date to estimate possible discontinuities. In practice, this means setting an earlier date  $R$  – than the actual reform date – in eq. (1) and re-estimating the equation. If discontinuous shifts in performance are really induced by the reform, then no effect should be found at these anticipated dates. This is indeed the case for all the results presented here, where placebo tests are run by anticipating the date of the reform by up to 3 quarters, in models with quarterly data, or by up to 6 months in models with monthly data.

A second issue concerns possible manipulations around the threshold. For example, if the introduction of the *contrato emprendedores* were anticipated, employers eligible for the subsidy could delay hiring from before to after the reform in order to enjoy the subsidy. However, the details and the breadth of the reform were never mentioned in the programme of the PPE before the November 2011 elections that the party won and was not made public until well after the inaugural address of Prime Minister Rajoy made in front of the parliament at the end of December 2011. It is therefore reasonable to assume that if threshold manipulation occurred, that is if firms postponed certain choices until the approval of the reform, this phenomenon concerned, at worst, only the period January-March 2012. Under these assumptions, threshold manipulation is not an issue in the regressions estimated on quarterly data because the outcome of any firm choice, which was delayed from January to March 2012, is included in the same quarter, with no effect on the average outcome of the quarter. In the case of estimates based on monthly data, baseline models are re-estimated excluding the period from January to March 2012 from the sample as an additional robustness check.

The fact that discontinuous patterns of labour market performance occurring around February 2012 are used to identify the effect of the 2012 reform makes it impossible to distinguish its impact from that of other institutional changes occurring around the same date. In particular, this is the case of the Agreement on Employment and Collective Bargaining 2012-2014, signed by the main business associations and trade unions – CEOE, CEPYME, CCOO and UGT – at the end of January 2012. This agreement promotes internal flexibility, as a mean to preserve employment, as well as commits to wage moderation and the expansion of performance-related pay.

A number of provisions, however, also either entered into force, *de jure* or *de facto*, after the date of approval of the main reform (February 2012) or were modified since then. This makes more difficult to identify unambiguously discontinuous patterns in the data. However, to the extent that the effects of subsequent policy adjustments are likely to go in the same direction of those of the February 2012 reform, results presented here are likely to represent only an underestimate of the true effect. Of course, if the direction of the impact of subsequent policy interventions were different, this argument would be invalid.

59. For further information and methodology, see [www.fedea.net/indice/indice-f.html](http://www.fedea.net/indice/indice-f.html).

This annex presents in detail methodology and empirical results dataset-by-dataset. The first section presents the analysis of the impact of the reform on labour costs, based on data from Spanish Quarterly Labour Cost Survey; the second section looks at hiring rates on the basis of data from the *Encuesta de la Poblacion Activa*; the third section studies new permanent contracts using the monthly statistics on contracts published by SEPE; the fourth examines the differential trends in collective and individual dismissals using the monthly statistics on unemployment benefits published by SEPE; the fifth studies separation rates using the Encuesta de Coyuntura Laboral; and the sixth section examines transitions from unemployment to employment using longitudinal data from the social security register.

## Labour costs

### Methodology

Unit labour costs measure the average nominal cost of labour per unit of output and are calculated as the ratio of total nominal labour costs to real output. Of particular interest for this report are wage and salary costs: the 2012 reform of collective bargaining is, in fact, expected to reduce the growth rate of nominal wage and salary costs per unit of output in times of crisis. Obviously the evolution of labour costs is strongly affected by the sectoral composition of activities. For this reason the analysis is carried out using data at the industry level (at the 1 digit of the NACE rev. 2 classification), using data from the Spanish Quarterly Labour Cost Survey and Quarterly National Accounts from the first quarter of 2005 to the second quarter of 2013 and focussing mainly on the non-agricultural business sector. However, to the extent that productivity data are not available at the same level of disaggregation (the industry classification used in the quarterly national accounts being slightly more aggregate), the wage and salary component of the harmonised index of labour costs per effective hour worked is used as dependent variable and hourly labour productivity (and/or other variables capturing it) are included as controls. One additional complication stems from seasonality: insofar as labour compensation vary significantly from one quarter to another due to the timing of payment of specific bonuses, only year-on-year changes in the harmonised index of labour costs can be meaningfully analysed. The estimated model, derived from the general one of eq. (1), can be written as

$$\Delta \log LC_{jt} = \beta_u u_t + \beta_\pi \Delta \log \pi_{jt} + \beta_c \Delta \log CPI_t + \Delta X_{jt} \gamma + \sum_{s=1}^5 \lambda_{js} (t-R)^s + \delta I_{t>R} + D_t + D_j + \varepsilon_{it}$$

where  $LC$  is the labour cost index in industry  $j$  at time  $t$  (wage costs per effective hour, adjusted for calendar days but not for seasonality),  $\pi$  is hourly productivity,  $CPI$  is the harmonised price index,  $X$  is a vector of workforce and job characteristics (the share of open-ended contracts, the share workers with less than one year of tenure, the share of three education categories, the share of four age categories, and the share of women),<sup>60</sup>  $u$  stands for the national-level standardised unemployment rate,  $R$  is the date of the reform,  $I$  is the indicator function,  $D$  stands for quarterly and industry dummies, and  $\Delta$  denotes year-on-year changes ( $t/t-4$ ). As residuals in this model are inevitably serially-correlated, errors are adjusted for clustering on both time and industry. As the reform is expected to affect the quarterly growth rate of labour costs from the first quarter of 2012, it should affect their year-on-year growth only slowly. Therefore, in contrast with other estimation exercises reported in this annex (see below),  $R$  is set at the beginning of the second quarter of 2012 in the baseline specification. Finally, the time trend is included in two alternative ways: in one series of specifications a 5<sup>th</sup>-order aggregate, homogeneous polynomial trend is included,<sup>61</sup> while in a second series a linear trend is allowed to vary across industries to capture industry heterogeneity in growth patterns. To the extent that only 5 quarters are observed where  $I$  is equal 1, the parameters of polynomial trends are not assumed to change over time.

60. These data are from the labour force survey (*Encuesta de la Poblacion Activa*, EPA).

61. The 5th order term is significant in all specifications.

## Results

Table A1 presents the key results. In the two baseline models, the impact of the reform on the growth of labour costs, conditional on productivity growth and other controls is estimated between 1.2 and 1.9 percentage points, significant at the 5% statistical level. Similar results are obtained with the following alternative specifications (not reported in the table but available upon request): i) reducing the order of the polynomial trend (or not including any trend); ii) substituting changes in industry-level log productivity with changes in either aggregate productivity or industry-level log employment, or including the latter as an additional covariate;<sup>62</sup> and iii) estimating the models with seasonally-adjusted data.

Table A1. **The effect of the reform on year growth of labour costs**

Industry-level equations, quarterly data

	Post-reform dummy	Placebo tests		
	Baseline (1)	One quarter before (2)	Two quarters before (3)	Three quarters before (4)
Model:				
5-th order polynomial	-0.019** (0.009)	-0.006 (0.011)	0.020* (0.011)	0.021 (0.013)
Industry-specific trend	-0.012** (0.005)	-0.005 (0.006)	0.004 (0.005)	0.009* (0.005)

*Note:* The dependent variable is the year-on-year quarterly change of the logarithm of the industry-level wage and salary component of the harmonised labour cost index. Each cell refers to a different specification. Robust standard errors, clustered on time and industry, in parentheses. All equations also control for the unemployment rate, change in log hourly productivity, quarter and industry dummies, changes in the log consumer price index, and changes in the industry composition of the workforce (that is, for each industry, the share of: open-ended contracts, workers with less than one year of tenure, 3 education categories, 4 age categories, and women). The post-reform dummy takes value 1 from the second quarter of 2012. In placebo tests it is replaced with a dummy taking value 1 from the fourth, third and second quarter of 2011 in columns 2, 3 and 4, respectively. \*\*  $p < 0.05$ , \*  $p < 0.1$

Placebo tests are implemented by replacing the post-reform dummy with dummies taking value 1 from the beginning of either the fourth or the third or the second quarter of 2011.<sup>63</sup> In all cases, estimates show either an insignificant or a positive and marginally significant effect of the “placebo”, therefore confirming that the estimated effects estimated in baseline models can be attributed to the reform.

## Hiring rates

### Methodology

Hiring rates are normally defined as new hires in a given period over employment in the same period. The microeconomic equivalent of this concept at the individual level is the probability of having been hired in a period of duration  $h$  before the reference week. In other words, one can estimate the effect of the

62. Short-term changes in employment and productivity are typically very strongly negatively correlated, therefore changes in the level of employment can be used to capture variations in productivity, since productivity by industry is not available at a sufficiently disaggregate level (the expected sign of the coefficient of employment is therefore negative). This allows also extending the number of covered industries. In fact, mining, water and electricity and gas are excluded from baseline specifications since productivity data are not available for these industries. When employment is also included in these specifications while already controlling for productivity changes, this is done to better control for possible worker selection.

63. Since the first quarter of 2012 is the quarter when the reform was implemented, a placebo test setting the placebo-reform dummy equal to 1 since the start of that quarter cannot be easily interpreted and is therefore not reported.

reform on the hiring rate by estimating its impact on the probability that an employee has tenure shorter than  $h$ . The following regression discontinuity model is estimated on individual quarterly data from the labour force survey (*Encuesta de la Población Activa*, EPA, cross-sectional file with a 2-digit industry classification) from the first quarter of 2008 to the second quarter of 2013:<sup>64</sup>

$$H_{ijt} = \beta_u \log u_t + \beta_e \Delta \log E_{jt} + X_{ijt} \gamma + \sum_{s=1}^5 \lambda_s (t - R)^s + \delta I_{t>R} + D_t + \varepsilon_{ijt} \quad (2)$$

where  $H$  is an indicator variable taking value 1 if the individual  $i$  in region  $j$  has job tenure lower or equal to 3 months at time  $t$ .  $H$  refers alternatively to all hires, hires on permanent contracts and hires on temporary contracts. The sample is restricted to all wage and salary employees in the non-agricultural business sector. As far as control variables are concerned,  $u$  is the quarterly standardised unemployment rate,  $E$  is regional employment,  $X$  is a vector of individual characteristics (70 2-digit industry dummies, gender, 10 age categories, 7 education categories, 10 occupational categories, and dummies for being non-native, having multiple jobs and having changed municipality in the last year).<sup>65</sup> Finally, as in eq. (1),  $R$  is the date of the reform (set at the first quarter of 2012),  $I$  is the indicator function,  $D$  stands for quarterly dummies,  $\Delta$  denotes changes and Greek letters stand for parameters to be estimated, except for  $\varepsilon$ , which represents a standard error term. Finally, a 4<sup>th</sup>-order aggregate homogeneous polynomial trend is included,<sup>66</sup> in baseline specifications. To the extent that only 6 quarters are in the post-reform sample, the parameters of the polynomial trends are not assumed to change over time.

## Results

Baseline estimates, reported in Table A2 suggest that the 2012 reform increased the hiring rate – measured as the proportion of employees with 3 month of tenure or less – by about 8% (that is a percentage-point marginal effect of 0.64 percentage points). With a 13% increase (corresponding to a percentage-point marginal effect of 0.14 percentage points), the estimated percentage effect is larger in the case of hiring on open-ended contracts. Very similar results – in percentage terms – are obtained if the sample is restricted to employees with an open-ended contract only. A somewhat stronger effect is estimated in the case of hiring on open-ended full-time contracts – 18% increase – corresponding to a percentage-point marginal effect of 0.16 percentage points). By contrast, the estimated percentage effect is much smaller in the case of hiring on temporary contracts, with a 7% increase (corresponding to a percentage-point marginal effect of 0.5 percentage points).

All the results presented in Table A2 are robust to i) specifying eq. (2) as a probit model instead of a linear probability model; ii) increasing the order of the polynomial trend<sup>67</sup> (or not including any trend);<sup>68</sup> iii) substituting changes in regional employment with, alternatively, changes in industry real value added or changes in unemployment rates; and iv) excluding all aggregate controls except polynomial time trends from the specification. By contrast, the only exception is the result on hiring on fixed-term contract, which is not robust to the exclusion of the polynomial trend.

64. The sample is limited to this period due to the change in industry classification that occurred between 2007 and 2008.

65. All individual data are from EPA.

66. The 4-th order term is significant in all specifications.

67. Although higher-order terms turn out to be statistically insignificant.

68. However, if a lower-order polynomial trend is included, the effect of the reform on the hiring rate of permanent workers is insignificant, although still positive.

Table A2. The effect of the reform on the probability of having tenure shorter than three months

Individual-level equations, quarterly data					
Dependent variable	(1) Hired	(2) Hired, permanent	(3) Hired, permanent	(4) Hired, full-time, Permanent	(5) Hired, fixed-term
Post-reform dummy	0.00646*** (0.00185)	0.00135** (0.00061)	0.00183** (0.00080)	0.00156** (0.00062)	0.00511** (0.00192)
Sample restricted to perm. workers	No	No	Yes	No	No
Observations	712,393	712,393	551,429	712,393	712,393
R-squared	0.066	0.004	0.012	0.004	0.067

Note: Hired stands for a dummy indicating that the worker has been hired in the three months preceding the reference week. Robust standard errors, clustered on time, in parentheses. All equations control for the unemployment rate, change in regional employment, quarterly dummies, a 4<sup>th</sup> order polynomial in time (quarters), 70 2-digit industry dummies, gender, 10 age categories, 7 education categories, 10 occupational categories, and dummies for being non-native, having multiple jobs and having changed municipality in the last year. \*\*\* p<0.01, \*\* p<0.05.

Placebo tests are then run for all specifications by “anticipating” the date of the reform by up to 3 quarters (Table A3). None of the placebo effect is significantly positive. However for both total hiring and, in particular, hiring on temporary contracts, placebo effects are significantly negative. This suggests some possible misspecification of the business-cycle component, so that the attribution of the increase in hiring on temporary contract to a genuine effect of the reform must be considered more uncertain.

Table A3. The effect of different placebos on the probability of having tenure shorter than three months

## New permanent contracts

The monthly statistics on contracts, published by SEPE, allows replicating and deepening the analysis of hiring on permanent contracts. In fact, while EPA covers a sample of few tenth of thousands employees and is available only at the quarterly base, contract statistics are published monthly and are based on compulsory administrative declarations from all employers and therefore cover the entire population. In

addition a breakdown of new contracts is available by firm size, which is important given that certain provisions of the 2012 reform are applicable only to firms below a certain size threshold.

### Methodology

In order to assess the impact of the reform on hiring on permanent contract, the following class of regression-discontinuity models is estimated, using on aggregate monthly data for the period January 2006–July 2013:

$$\log NP_t = \beta_u u_t + \beta_d \Delta u_t + X_t \gamma + \sum_{s=1}^5 \lambda_s (t - R)^s + \delta I_{t>R} + \sum_{s=1}^5 \mu_s I_{t>R} (t - R)^s + D_t + \varepsilon_t \quad (3)$$

where  $NP$  is the number of new permanent contracts at time  $t$ ,  $u$  is the monthly standardised unemployment rate,  $X$  is a vector of variables capturing workforce composition of new hires (shares of 3 education categories, 5 age categories and women),  $R$  is the date of the reform,  $I$  is the indicator function,  $D$  stands for monthly dummies,  $\Delta$  denotes changes and Greek letters stand for parameters to be estimated. All data are from the monthly statistics on contracts published by SEPE, except for the unemployment rate. As the identification is based on a time discontinuity, standard errors are adjusted for clustering on time. Finally, a 5<sup>th</sup>-order aggregate polynomial trend is included, in baseline specifications.<sup>69</sup> Since 18 observations are available in the post-reform period, the time trend is alternatively specified as homogeneous (same parameters before and after the reform) and heterogeneous (different parameters before and after the reform).

Eq. (3) is estimated for the whole economy and then separately for firms above and below the threshold of 50 employees (since only firms below the threshold are eligible for the *contrato emprendedores* introduced by the reform). Then, both groups of firms (above and below this threshold) are divided further into those with size above and below 25 employees and those of size above and below 100 employees.

### Results

As shown in Table A4, the 2012 reform increased hiring on regular open-ended contracts by 20%-30%. If firms are split in two subsamples – those with 50 or fewer employees and those with more than 50, no significant increase is observed for the largest firms. By contrast, no matter how the time trend is specified, the reform is estimated to have increased the number of new contracts by about 42%, and this estimated impact is always significant at the 1% level. For these two groups of firms the predicted effect of the reform is plotted in Figures A1 and A2. For firms with 50 or fewer employees, the baseline model with homogeneous time trend predicts that the reform raised the number of new open-ended contracts by at least 25 000 units, while no effect is detectable for larger firms. These trends are also reflected in the evolution of the share of regular open-ended contracts in total hiring, which is estimated to have been raised by about 3 percentage points (or about 30%) in firms with 50 or fewer employees, while no significant effect emerges for larger firms.<sup>70</sup>

69. The 5-th order term is significant in all specifications.

70. These figures (not shown in the table) are obtained by replacing the log of the number of new contracts with the share of permanent contracts in new hires in eq. (3). All results presented here are robust if the share of regular open-ended contracts in total hiring is used as dependent variable instead of the number of open-ended contracts.

Table A4. The effect of the reform on new permanent contracts

Panel A. Homogeneous trend, monthly data							
	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Sample (firm size)	All	1to50	>50	1to25	26to50	51to100	>100
Post-reform dummy	0.217* (0.124)	0.421*** (0.110)	0.132 (0.084)	0.463*** (0.109)	0.281*** (0.095)	0.231** (0.103)	0.067 (0.080)
Observations	91	91	91	91	91	91	91
R-squared	0.957	0.949	0.970	0.946	0.959	0.953	0.972

Panel B. Heterogeneous trend							
	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Sample (firm size)	All	1to50	>50	1to25	26to50	51to100	>100
Post-reform dummy	0.334*** (0.108)	0.424*** (0.101)	0.150 (0.116)	0.456*** (0.0942)	0.266* (0.136)	0.286** (0.117)	0.099 (0.127)
Observations	91	91	91	91	91	91	91
R-squared	0.965	0.959	0.971	0.956	0.966	0.960	0.973

Note: Dependent variable: logarithm of new open-ended contracts. Robust standard errors, clustered on time, in parentheses. Each equation includes level and changes in the standardised unemployment rate, the shares of 3 education categories, 5 age categories and women in new contracts and a 5-th order polynomial trend in time (months), which in Panel B is assumed to differ between before and after the reform. \*\*\* p<0.01, \*\* p<0.05, \* p<0.1

When the data are further disaggregated by firm size, the greatest estimated expansion in the number of new permanent contracts induced by the reform is found in very small firms with 25 employees or less (45%-46%; see Table A4). In firms between 26 and 100 employees the effect is somewhat more limited. The reform is estimated to have raised the number of new permanent contracts by 26%-28% in firms with 26 to 50 employees and by 23%-28% in firms with 51 to 100 employees. By contrast, no significant effect is observed for larger firms.<sup>71</sup>

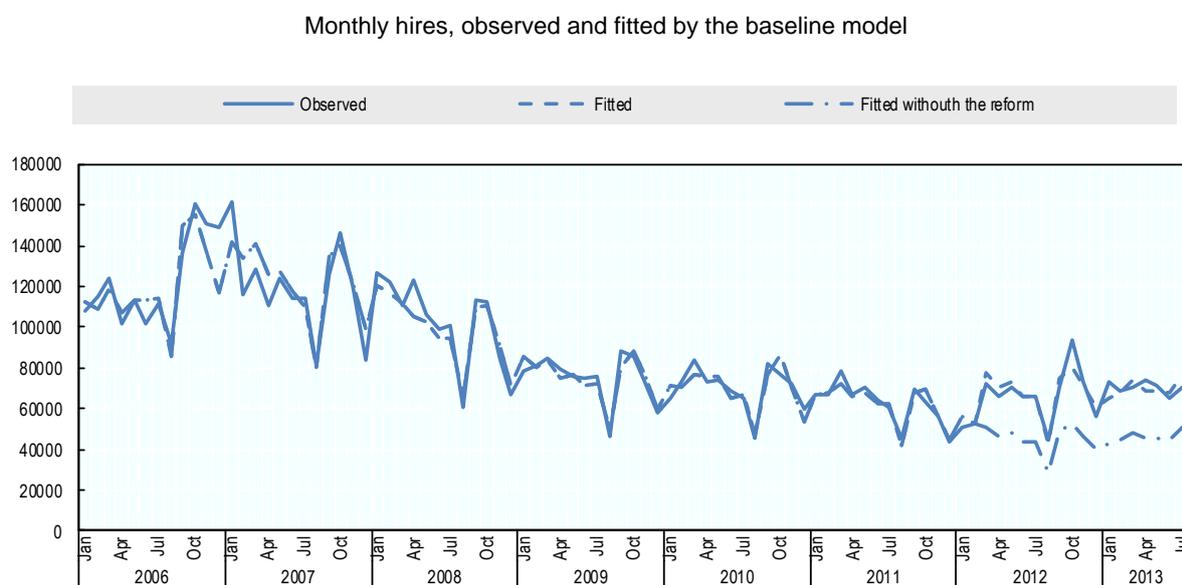

All the results presented in Table A4 are robust to i) changing the order of the polynomial trend (or not including any trend); ii) excluding workforce controls; iii) substituting polynomial trends with year dummies; iv) substituting changes in the unemployment rate with either changes in the FEDEA index or the logarithm of employment as measured by the number of workers enrolled in the general social security regime; and v) excluding all aggregate controls except polynomial time trends from the specification.

Placebo tests are then run for all specifications by “anticipating” the date of the reform by up to 6 months. Table A5 presents the results for the case of homogenous time trends. Results are however similar in the case of heterogeneous trends and/or if changes in the unemployment rate are replaced by

71. No matter how the time trend is specified, the effect on firms with 25 employees or less appears also significantly larger than that of firms with 26 to 50 employees. Similarly the effect on firms with more than 100 employees appears significantly smaller than that of 51 to 100 employees. By contrast, the difference in the estimated impact between firms with 26 to 50 employees and 51 to 100 employees is statistically insignificant at conventional levels.

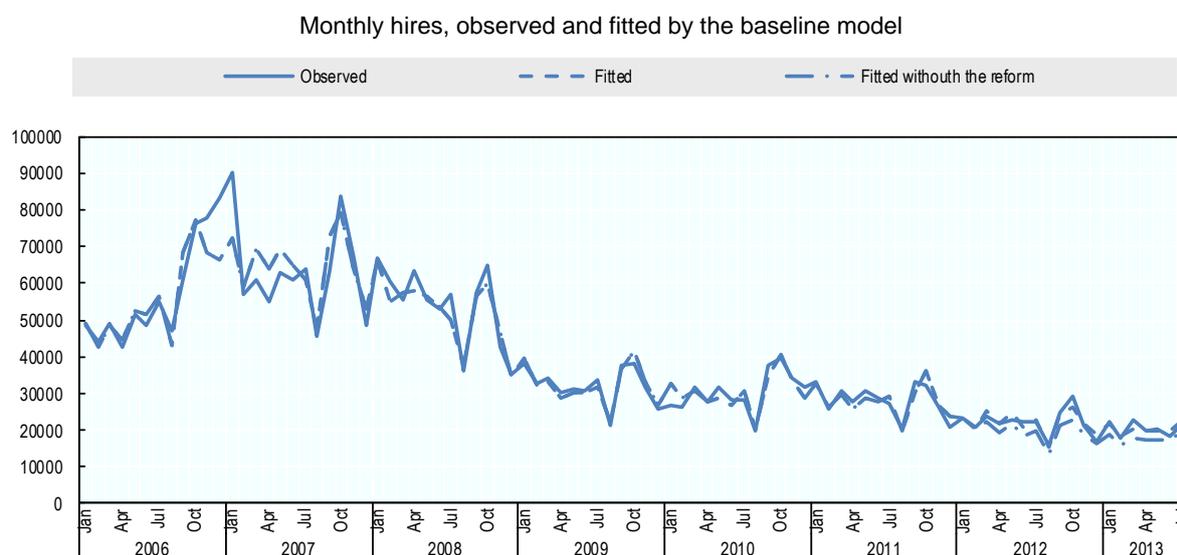

changes in the FEDEA index. In all cases where a significant effect of the reform is estimated with eq. (3), placebo tests show no significant effect if the date of the reform is set at the beginning of January 2012 or before. This suggests that the estimated effects in Table A4 can be genuinely attributed to the reform.

Figure A1. **New hires with a permanent contract in firms with 50 or fewer employees, 2006-2013**

Note: The figure presents the number of new permanent contracts signed each month, as observed in raw data and as fitted using estimates of Table A4, Column 2 (including netting out the effect of the post-reform dummy).

Figure A2. **New hires with a permanent contract in firms with more than 50 employees, 2006-2013**

Note: The figure presents the number of new permanent contracts signed each month, as observed in raw data and as fitted using estimates of Table A4, Column 3 (including netting out the effect of the post-reform dummy).

Table A5. The effect of different placebos on new permanent contracts

Homogeneous trend, monthly data							
Sample (firm size)	(1) All	(2) 1to50	(3) >50	(4) 1to25	(5) 26to50	(6) 51to100	(7) >100

Placebo-reform Dec 11	-0.061 (0.090)	-0.044 (0.101)	-0.049 (0.089)	-0.046 (0.099)	-0.104 (0.114)	-0.155 (0.105)	-0.016 (0.084)
Placebo-reform Aug 11	-0.119 (0.090)	-0.135 (0.084)	-0.123 (0.081)	-0.146* (0.079)	-0.135 (0.122)	-0.193* (0.107)	-0.061 (0.069)

Note: Dependent variable: logarithm of new open-ended contracts. Each cell refers to a different specification. Robust standard errors, clustered on time, in parentheses. Each equation includes level and changes in the standardised unemployment rate, the shares of 3 education categories, 5 age categories and women in new contracts and a 5-th order polynomial time trend, which in Panel B is assumed to differ between before and after the reform. \* p<0.1

A breakdown by type of transition is also available in the data, which allows estimating eq. (3) separately for new employment relationships and conversions of temporary contracts into open-ended ones (Table A6).

Table A6. The effect of the reform on new permanent contracts, by type of transition

Panel A. Conversions							
Sample (firm size)	(1) All	(2) 1to50	(3) >50	(4) 1to25	(5) 26to50	(6) 51to100	(7) >100
Post-reform dummy	0.159 (0.182)	0.306* (0.163)	0.213* (0.123)	0.325** (0.162)	0.266* (0.136)	0.387** (0.161)	0.121 (0.102)
Observations	91	91	91	91	91	91	91
R-squared	0.925	0.924	0.921	0.919	0.931	0.907	0.924

Panel B. New employment relationships							
Sample (firm size)	(1) All	(2) 1to50	(3) >50	(4) 1to25	(5) 26to50	(6) 51to100	(7) >100
Post-reform dummy	0.240*** (0.090)	0.498*** (0.098)	0.046 (0.075)	0.562*** (0.103)	0.267*** (0.058)	0.041 (0.072)	0.012 (0.083)
Observations	91	91	91	91	91	91	91
R-squared	0.972	0.963	0.982	0.957	0.976	0.975	0.979

Note: Dependent variable: logarithm of new open-ended contracts, by type, estimated on monthly data. Robust standard errors, clustered on time, in parentheses. Each equation includes level and changes in the standardised unemployment rate, the shares of 3 education categories, 5 age categories and women in new contracts and a 5-th order, homogeneous polynomial time trend, which in Panel B is assumed to differ between before and after the reform. \*\*\* p<0.01, \*\* p<0.05, \* p<0.1

As far as conversions are concerned the effect of the reform is the greatest for firms with 51 to 100 employees (with a 39% estimated increase) followed by those with 1 to 25 employees (32% increase). However, while for the latter the estimated increase in new open-ended employment relationships is much

larger (56% increase), there is essentially no effect on these for the former. As regards firms with 26 to 50 employees the effect of the reform appears similar on both conversions and new open-ended employment relationships (about 27% in both cases), although less precisely estimated for the former.<sup>72</sup>

### Collective and individual dismissals

Inflows onto unemployment benefits, by reason of inflow, are a reliable source of data to distinguish the effect of the 2012 reform on individual and collective dismissals.<sup>73</sup>

### Methodology

The same class of regression-discontinuity models used in the previous section for new contracts (eq. 3) can be used to estimate the impact of the reform on the number of individual and collective dismissals, using on aggregate monthly data (January 2007-July 2013). Three differences are however in order: i) the dependent variable in this case will be replaced by either the logarithm of monthly inflows onto unemployment benefits due to, alternatively, collective or individual dismissals or the share of inflows due to collective dismissals in total inflows due to dismissals; ii) the logarithm of inflows due to other reasons than that those measured in the dependent variable replaces changes in the unemployment rate (since the former seems more appropriate in this case); and iii) to the extent that this model is used to study mainly collective dismissals and at least one-month consultations with trade-unions are required by post-reform regulations in the case of collective dismissals, the post-reform dummy takes value one only one-month after the reform (therefore taking value 1 from April 2012).<sup>74</sup> All data are from the monthly statistics on unemployment benefits (*Prestaciones por desempleo*) published by SEPE. Inflows by dismissal exclude those resulting from conciliation settlements, court rulings or contract suspensions, but include those ex ley 45/2002 (individual dismissals for which benefits are claimed before that a court can rule whether the dismissal is fair or unfair). Inflows data considered here are limited to workers who are eligible to standard unemployment benefits because of sufficient previous contributions and contribution periods (*Prestaciones de nivel contributivo*). They exclude, therefore, workers eligible only for other type of unemployment-related subsidies (*Prestaciones de nivel asistencial*). Since published data do not contain a breakdown of inflows by workers' characteristics, these controls are not included. As the identification is based on a time discontinuity, standard errors are adjusted for clustering on time.

In order to capture the business-cycle (over and above levels of the unemployment rate and other inflows onto unemployment benefits), models of the type of eq. (3) include a polynomial trend up to 5<sup>th</sup> order, which can be either homogeneous (same parameters before and after the reform) or heterogeneous (different parameters before and after the reform) depending on the specification. The baseline specification includes a homogeneous polynomial trend up to the highest order  $n$  such that the  $n$ -th term is not insignificant (in practice, the 2<sup>nd</sup> order in the case of the number of collective dismissals, the 3<sup>rd</sup> order in the case of its share and the 5<sup>th</sup> order in the case of individual dismissals).

### Results

Taking baseline estimates with homogeneous trends at face value, the 2012 reform is estimated to have reduced inflows onto unemployment benefits for reasons of collective dismissals by about 32%

72. Similar estimates are obtained by using heterogeneous trends and/or replacing changes in unemployment with changes in the FEDEA index.

73. However, it must be kept in mind that available data are limited to workers who have sufficiently long contribution histories to be eligible for unemployment benefits.

74. This seems appropriate to minimise the risk of counting as subsequent to the reform dismissals that were originated by a collective-dismissal procedure which in fact started before the reform.

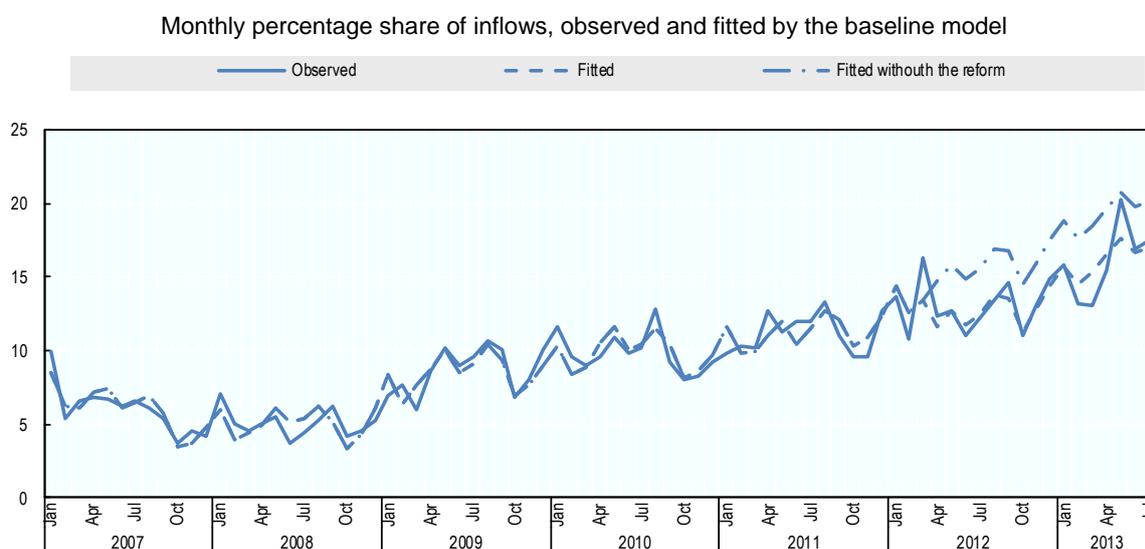

(Table A7). By contrast, individual dismissals decreased by about 6% only. Moreover, this effect is significant only at the 10% level. Results are similar with heterogeneous trends (not shown in the table). This evolution is reflected in the estimated effect of the share of collective dismissals in total dismissals (see also Figure A3). In fact, the reform is estimated to have reduced this share by about 3.1 percentage points (that is about 30%).

Table A7. **The effect of the reform on inflows onto unemployment benefits due to dismissal**

Dependent Variable	(1) Log Collective dismissals	(2) Log Individual dismissals	(3) Share Collective dismissals
Post-reform dummy	-0.316*** (0.084)	-0.060* (0.035)	-3.146*** (0.856)
Observations	79	79	79
R-squared	0.948	0.964	0.928

Note: Dependent variable: Columns 1 and 2: logarithm of inflows onto unemployment benefits for the reason indicated in the column title; Column 3: share of collective dismissals in inflows due to any type of dismissal. All equations control for the unemployment rate, a polynomial trend in time (months) and inflows in unemployment benefits for reasons different from those reported in the column title. A 2<sup>nd</sup>-order polynomial is included in Column 1, a 5<sup>th</sup>-order polynomial in Column 2 and 3<sup>rd</sup>-order polynomial in Column 3. Robust standard errors, clustered on time, in parentheses. \*\*\* p<0.01, \*\* p<0.05, \* p<0.1

Figure A3. **Share of inflows onto unemployment benefits due to collective dismissal in total inflows due to dismissal, 2007-2013**

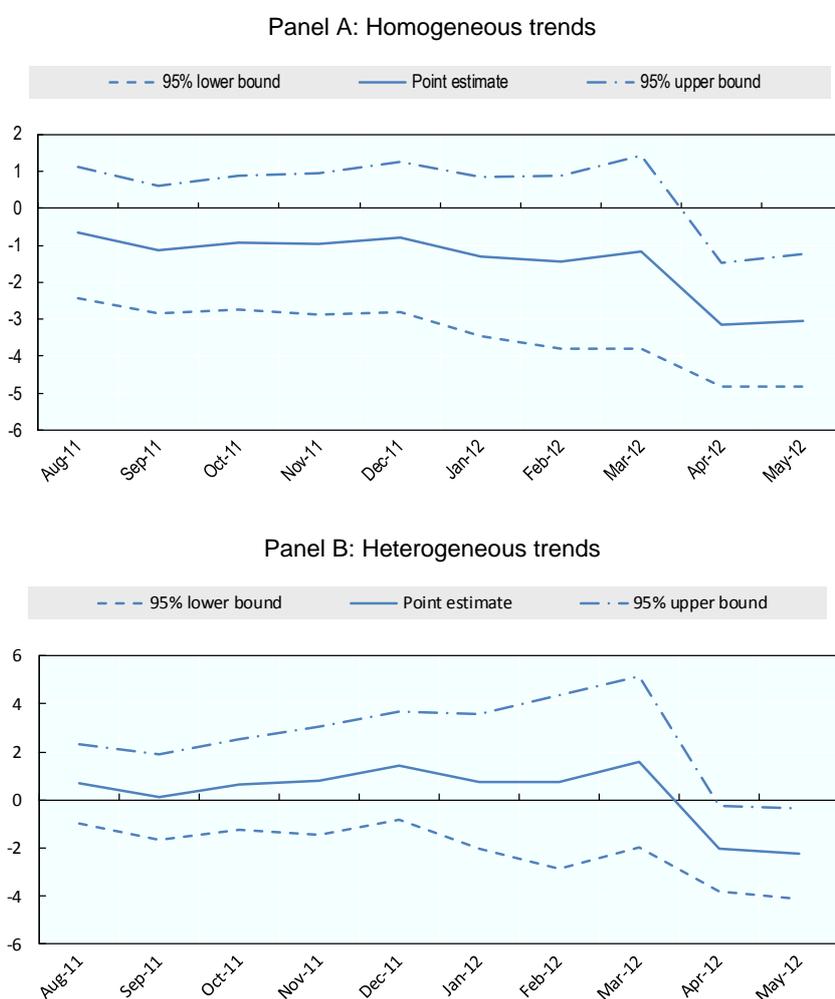

Note: The figure presents the monthly percentage share of inflows in unemployment benefits due to collective dismissal in total inflows due to dismissal, as observed in raw data and as fitted using estimates of Table A7, Column 3 (including netting out the effect of the post-reform dummy)..

Results on collective dismissals are robust to i) substituting homogeneous trends with heterogeneous trends; ii) changing the order of the polynomial trend (or not including any trend);<sup>75</sup> and iii) replacing changes in the unemployment rate with changes in the FEDEA index. By contrast, results on individual dismissals are sensitive to the specification of the polynomial trend. In fact, if a 2<sup>nd</sup> or 3<sup>rd</sup>-order polynomial is specified, the point estimate is even positive, although insignificant.

Placebo tests are then run for all specifications by “anticipating” the date of the reform by up to 6 months. Figure A4 presents the results for the share of collective dismissals. It turns out that if the the date of the “placebo-reform” is set even one single month before, its estimated effect would be insignificant, no matter whether the trend is modelled as homogeneous or heterogeneous. This suggests that the estimated effects in Table A4 can be genuinely attributed to the reform.

Figure A4. **The effect of different placebos on the share of inflows onto unemployment benefits due to collective dismissals**

*Note:* The figure reports estimated coefficients and confidence interval obtained by estimating the specification reported in Table A7, Column 3, substituting the post-reform dummy with a dummy taking value 1 from the indicated dates. Apr-12 corresponds to the estimated effect of the true reform (measured through the coefficient of the post-reform dummy).

75. However, the effect on the share of collective dismissals become insignificant is no trend (or a linear, homogeneous trend) is included.

## Worker separations at the establishment level

### Methodology

Worker separations at the establishment level are analysed using the *Encuesta de Coyuntura Laboral* (ECL), an establishment-level<sup>76</sup> survey that follows establishments over time and registers its worker flows. Around 12,800 establishments are surveyed each quarter. This sample is representative of all establishments in the private sector and covers all workers registered in the General Regime of the Spanish Social Security Register (as well as those in the Special Mining Regime).

Separation rates at the establishment level are defined as the number of separations in each quarter divided by the average of total employment between the start and the end of the period at each establishment. Separation rates are computed both for full-time and part-time employment, and distinguishing between those separations that are due to end of contract for temporary workers, due to dismissals of permanent workers, due to end of season for seasonal workers with an open-ended contract – “*fijos discontinuos*” – and due to other reasons (including retirements, voluntary separations, deaths, etc.).<sup>77</sup>

The following regression discontinuity model is estimated on quarterly establishment-level data from ECL for the period 2006 to 2012, for which micro data are available:

$$SR_{jt} = \alpha \log u_t + \beta \Delta \log E_{jt} + F_{jt} \gamma + \sum_{s=1}^5 \lambda_s (t - R)^s + \delta I_{t>R} + Q_t + \mu_j + \varepsilon_{jt} \quad (4)$$

where  $SR$  corresponds to the separation rate of the establishment  $j$  in quarter  $t$ .  $SR$  refers alternatively to separation rates of all workers, of full-time/part-time as well as separation rates due to end of contract, dismissals, end of season and other reasons. The sample is restricted to all establishments in the private sector with at least ten workers on average for the whole period they are observed in the data. The estimation has as cyclical controls the quarterly standardised unemployment rate at the national level ( $u$ ) and the change in employment level (in logs) at the regional level ( $\Delta \log E$ ). In addition, several establishment characteristics  $F$  are included: industry, establishment size, region as well as average age and qualification structure in each sector in the region (extracted from LFS data).  $R$  is the date of the reform,  $I$  is the indicator function,  $Q$  stands for quarterly dummies, and  $\Delta$  denotes changes. Greek letters stand for parameters to be estimated, except for  $\varepsilon$  which represents a standard error term. The standardised unemployment rate is from OECD labour market statistics, while regional employment is measured by the number of workers enrolled in the general social security regime. Establishment fixed-effects  $\mu$  are included in fixed-effects regressions. As the identification is based on a time discontinuity, standard errors are adjusted for clustering on time.

An additional variable is added to control for the share of permanent (and temporary) contracts in the establishment, which is important when differentiating between types of separations. The results are robust to the inclusion of this variable.

76. The unit of observation is the social security account number (*Cuenta de Cotización*), which is unique for each firm at the provincial level. It does not correspond exactly to the plant or the firm level (as those firms established in different provinces are not linked), although for a matter of simplicity we will refer to each social security accounting unit as an “establishment”, hereafter. For each *Cuenta de Cotización*, it is possible to identify if the account corresponds to establishments with only one or several plants in the same province. Almost 90% of the observations have only one plant.

77. The separation rate of each type of workers (full/part-time, etc) is defined as the ratio between the number of separations of each type of workers divided by the average of total employment between the start and the end of the period at the establishment.

The estimation of equation (4) is performed using ordinary least squares as well as fixed-effect models<sup>78</sup> for all establishments in the private sector with more than 10 employees. The equation is also estimated for small establishments with less than 50 employees only, with similar results. Results shown include a polynomial time trend up to the 5<sup>th</sup> order but are robust to changing the order of the polynomial time trend.

## Results

The baseline results (see results in Table A8) suggest that the 2012 reform significantly reduced the share of workers leaving the establishment in a given quarter. The estimated coefficient for the overall separation rate implies that the reform reduced overall separation rates by about 24%, although the exact point estimates differ slightly depending on the specification. The effect of the reform has been particularly sizeable for part-time workers (for which separation rates are 41% lower due to the reform).

Table A8. The effect of the reform on separation rates at the establishment level

Quarterly data				
	Post-reform dummy	Placebo tests		
	Baseline	One quarter before reform	Two quarters before reform	Three quarters before reform
	(1)	(2)	(3)	(4)
Separation rates:				
Overall	-0.018*** (0.006)	-0.010* (0.006)	0.005 (0.006)	0.006 (0.005)
Full-time	-0.006* (0.003)	-0.004 (0.003)	0 (0.004)	0.003 (0.003)
Part-time	-0.010** (0.004)	-0.007 (0.005)	0.008 (0.005)	0.005 (0.004)
End of Contract	-0.016** (0.006)	-0.016** (0.008)	0.017** (0.008)	0.013* (0.006)
Dismissal	-0.002 (0.001)	-0.002** (0.001)	-0.001 (0.001)	0.002* (0.001)
End of Season	-0.009** (0.004)	-0.008 (0.005)	0.013*** (0.004)	0.009** (0.004)
Other	0.001 (0.002)	0.003** (0.001)	0 (0.002)	-0.002 (0.001)

Note: Each cell corresponds to the OLS coefficient of the post-reform (or the placebo test) dummy from a regression with each separation rate as dependent variable. All equations control for the unemployment rate, change in regional employment, a 5<sup>th</sup> order polynomial in time (quarters), establishment size, quarterly dummies, age and education composition of the establishment workforce and region and sector dummies. Robust standard errors, clustered on time in parentheses. \*\*\*, \*\*, \*: significant at the 1%, 5% and 10% level, respectively.

In addition, establishment-level data allows disaggregating flows by contract type and reason of separation. The results point to a significant impact of the reform on separation rates due to the end of contract for temporary workers (for which separation rates decreased by 31%) and for seasonal workers

78. Alternatively, the estimation of equation (4) using a Tobit model is performed and similar results as OLS are found. In addition, substituting separation rates by the log of the absolute value of separations does not modify the results significantly.

(71% decrease), but show no impact on dismissal rates and separations for other reasons. An impact of the reform decreasing separation rates is still found when controlling for individual establishment effects, although the effect is not significant (not shown in the table), suggesting that the reform affected separation rates mainly by changing the composition of establishments.

Placebo tests are run for all the estimations by “anticipating” the date of the reform for up to 3 quarters. This is equivalent to substituting the date of the reform  $R$  by an earlier date and re-estimating the equation (4). The coefficient of the placebo reform, when the its date is set just one quarter before the true reform, is still negative and significant at the 5% for the separation rate due to the end of contract for temporary workers, suggesting caution in the interpretation of the baseline estimates as regards this covariate. Other placebo tests corresponding to two and three quarters before the reform show no significant effect for all the estimations, except for a positive and significant one in the cases of end of contract and end of season, which again suggests caution in interpreting the baseline results concerning these variables.

An additional robustness test has been undertaken by replacing the change in log regional employment ( $\Delta \log E$ ) by the FEDEA index of economic activity. The results are not sensitive to using one or the other indicator of the economic cycle.

## Transitions from unemployment to employment

### Methodology

Transitions from unemployment to employment are analysed using the *Muestra Continua de Vidas Laborales* (MCVL). This longitudinal dataset from social security registers covers employment histories of over one million individuals, making it a very good data source to study worker transitions out of unemployment. The MCVL covers around one in twenty persons registered in the social security and is representative of the whole population that had a relationship with social security in a given year<sup>79</sup>. These data are used to study the impact of the reform on the hazard rate out of unemployment using a discrete-time competing-risk duration model. The empirical strategy followed is similar to the one followed in García-Pérez and Muñoz-Bullón (2011).

The probability of exiting unemployment after a spell of duration  $d$  to enter either temporary employment or permanent employment is simultaneously estimated for the two types of exits within a competing-risk framework. Both possible transitions are modelled using a logistic distribution as given by:

$$\begin{aligned} \Pr(U_{it} = d, L_{it} | U_{it} \geq d) = & \\ & F(\alpha_0 + \alpha_1 \ln(U_{it}) + \alpha_2 \ln(U_{it})^2 + \alpha_3 \ln(U_{it})^3 + \alpha_4 X_{1it} + \alpha_5 X_{2it} + \alpha_6 X_{1it} * \ln(U_{it}) + \\ & + \alpha_7 \text{PrevEmpl}_{it} + \gamma \log u_t + \beta_1 \Delta \log E_{jt} + \beta_2 \Delta \log E_{jt} * \ln(U_{it}) + \sum_{s=1}^3 \lambda_s (t - R)^s + \delta I_{t > R} + m_t) \end{aligned} \quad (5)$$

where  $U$  refers to the duration of the unemployment spell, which ends at time  $t$  for the worker  $i$ ,  $L$  is after-transition employment contract-type (permanent or temporary) and  $X_1$  refers to the following individual characteristics: age and education categories and an indicator of whether the individual receives unemployment benefits or not. These are also included in interaction with the duration of the unemployment spell.  $X_2$  stands for controls for gender, migrant status and region, while *PrevEmpl* for characteristics of the previous job (sector, type of contract, and if the individual was dismissed or not) as

79. See García-Pérez (2008) for further details on the MCVL data and its usefulness to study labour market transitions.

well as the number of times the individual has been unemployed and the percentage of time he has been employed throughout his labour market career. Specifications include also as cyclical controls the monthly unemployment rate at the national level ( $u$ ) and the change in log employment at the provincial level ( $\Delta \log E$ ). However, in order to capture the business-cycle (over and above control variables), models of the type of eq. (5) include a polynomial trend up to the highest order  $n$  such that the  $n$ -th term is not insignificant (in practice, the 3<sup>rd</sup> order or 5<sup>th</sup> order depending on the specification). Finally,  $R$  is the date of the reform,  $I$  is the indicator function,  $m$  stands for monthly dummies, and  $\Delta$  denotes changes. Greek letters stand for parameters to be estimated. In order to distinguish the estimated impact of the reform between large and small establishments (to capture threshold effects) a four-fold competing-risk model is also estimated, with four possible exiting states (permanent/temporary in large/small establishments).<sup>80</sup>

Equation (5) is estimated for a sample of Spanish workers aged 16-64 during the period 2003-2012 (2006-2012 for the subsample differentiating by establishment size). Transitions from unemployment to employment are conditional on being unemployed for at least one day and durations are censored at 30 months of unemployment – that is, those spells lasting more than 30 months are considered to be censored at the 30<sup>th</sup> month.

## Results

The baseline results for the transitions from unemployment to employment (shown in Table A9) indicate that the 2012 reform increased significantly the probability of leaving unemployment and entering employment for any unemployment duration. The effect of the reform is significant as regards the probability for the unemployed of being hired on a permanent contract, which has increased by 24%, on average, during the first 6 months in unemployment where most transitions occur, although this probability remains very small in absolute terms. The effect of the reform on the probability to exit from unemployment into permanent employment is more sizeable for those being unemployed for less than 7 months than for those unemployed between 7 and 13 months or more than 13 months (Figure A5).

The reform seems to have increased as well the probability of leaving unemployment and entering temporary employment, although the effect is not significant in most specifications.<sup>81</sup> Thus, for unemployment durations no longer than 6 months, the reform appears to have raised the share of exits from unemployment to permanent employment in total exits from unemployment by about 14%, taking the point estimates at face value.

Results from transitions from unemployment to permanent employment also indicate a greater impact of the reform in small establishments than in larger ones (Table A4). The results from the estimation of the competing-risk hazard models suggest that the reform increased the average transition to a permanent contract – conditional on being unemployment for six months or less – by 26% in establishments with 50 or fewer employees, compared with 15% in establishments with over 50 employees (Figure A6). To the extent that the large majority of firms are mono-establishments, this points to a greater impact of the reform on hiring for smaller firms.

80. As for analyses based on the ECL, establishment here refer to the *Cuenta de Cotización*, which is unique for each firm at the province level.

81. However, in absolute terms, the estimated effect on transitions to permanent contracts is no smaller than that on transitions to temporary contracts. For example, taking point estimates at face value, in the first 6 months of unemployment, the average probability of a monthly transition to a temporary job increased from 18.6% to 19.9% due to the reform whereas the average transition to permanent employment increased only from 1.7% to 2.1%.

Table A9. The effect of the reform on Transitions out of Unemployment into temporary employment and into permanent employment

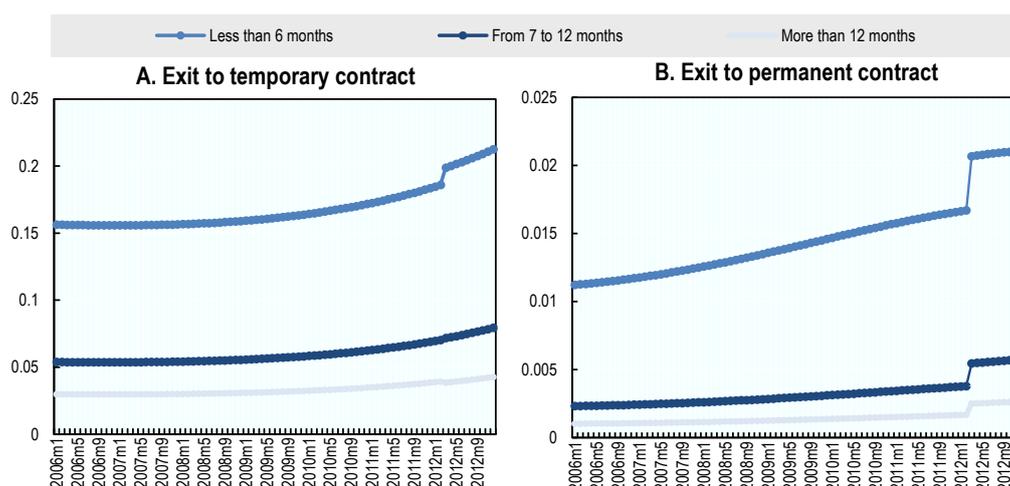

Monthly data, coefficients of the competing-risk hazard models

<b>Establishments with more than 50 employees</b>	<b>U to TC</b>	0.0947* (0.0514)	0.0574 (0.0574)	0.0117 (0.0690)	-0.00221 (0.0473)		
	<b>U to PC</b>	0.165*** (0.0629)	-0.0401 (0.0965)	-0.0290 (0.114)	0.205*** (0.0662)		

Note: U: unemployment; PC: permanent employment; TC: temporary employment. Coefficients within border lines refer to simultaneous estimates. The All equations control for the unemployment duration (in logs) up to the 3rd order, the national unemployment rate, change in regional employment (and its interaction with the unemployment duration (in logs)), a 3rd order polynomial in time (months) in the models of the first two lines and a 5th order polynomial in the others, age and education categories, an indicator if the individual receives unemployment benefits (and the interaction of those variables with the duration of the unemployment spell), gender, migrant status, region, characteristics of the previous job (sector, type of contract, and if the individual was dismissed), the number of times the individual has been unemployed, the percentage of time he has been employed as well as monthly dummies. The sample includes all individuals who have been unemployed at least one day. Unemployment durations are censored at 30 months in unemployment. Robust standard errors, clustered on time in parentheses. \*\*\*, \*\*, \*: significant at the 1%, 5% and 10% level, respectively.

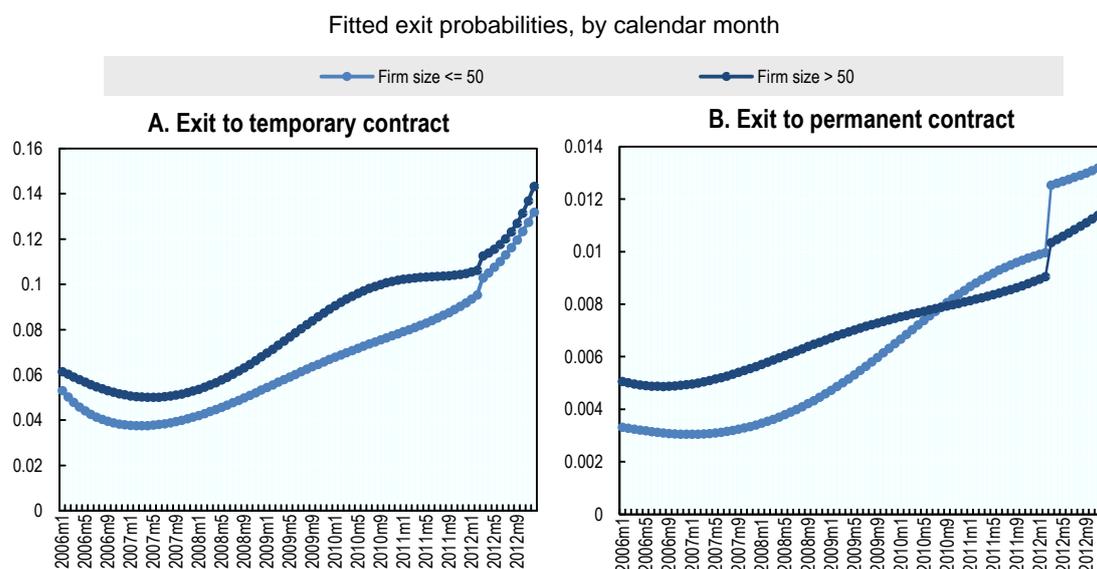

Figure A5. Exit from unemployment by type of contract and unemployment duration

Fitted exit probabilities, by calendar month

Note: The figure presents the average of estimated monthly probabilities of individual transitions from unemployment to employment by type of contract in the new job and unemployment duration (less than six months, from 7 to 12 months and more than 12 months), netting out the effect of the time trend and monthly dummies. The sample includes all individuals who have been unemployed at least one day. Unemployment durations are censored at 30 months in unemployment. Panel A refers to exits from unemployment to temporary contracts and Panel B to exits from unemployment to permanent contracts.

Figure A6. Exit from unemployment conditional on duration smaller or equal than 6 months, by type of contract and establishment size

Note: The figure presents the average of estimated monthly probabilities of individual transitions from unemployment to employment by type of contract in the new job and unemployment duration (less than six months, from 7 to 12 months and more than 12 months), netting out the effect of the time trend and monthly dummies. The sample includes all individuals who have been unemployed at least one day. Unemployment durations are censored at 30 months in unemployment. Panel A refers to exits from unemployment to temporary contracts and Panel B to exits from unemployment to permanent contracts.

Placebo tests are run for all the estimations by “anticipating” the date of the reform by up to three quarters. The coefficients are either non-significant or negative for all specifications, except for the placebo test three quarters before the reform for transitions to permanent employment in establishments with more than 50 employees. Similarly, some caution is required in interpreting baseline estimates since placebo test statistics are significant (albeit negative) when the placebo date is two quarters before the true reform. However, these statistics turn out to be insignificant when transition hazards are allowed differing across establishment types.

Several robustness checks have been performed as well, which include i) substituting the polynomial trend for calendar year dummies; ii) using polynomial time trends of different order; ii) performing the estimations separately by type of previous contract held, by age groups and by gender; iii) substituting regional unemployment rates for aggregate ones; and iv) replacing registered employment by the index of economic activity of FEDEA. Results presented in Table A9 are robust to these changes.

The effect of the 2012 reform has not been homogeneous on all individuals (Table A10). In particular, transitions from unemployment towards permanent employment have increased significantly more for those that had a temporary contract prior to becoming unemployed, while the effect remains insignificant for those who previously held a permanent contract. Symmetrically, the results suggest a marginally positive impact of the reform on the speed of transition towards a temporary contract only for those that had a permanent contract prior to becoming unemployed.

The reform seems also to have had a greater impact on younger workers, a population group severely affected by unemployment, than on older ones. Transition rates from unemployment towards permanent employment have increased more for individuals aged 18-30, compared to for those aged 31-44 and 45-64 (Table 6).

Finally, estimating the same models for transitions out of permanent or temporary contract yields an insignificant impact of the reform on these transition hazards.

Table A10. **The effect of the reform on Transitions out of Unemployment into temporary employment and into permanent employment, by personal characteristics**

## STRUCTURAL REFORMS AND MACROECONOMIC PERFORMANCE: INITIAL CONSIDERATIONS FOR THE FUND

### EXECUTIVE SUMMARY

Structural policies have become a prominent feature of today's macroeconomic policy discussion. For many countries, lackluster economic growth and high unemployment cloud the outlook. With fewer traditional policy options, policymakers are increasingly focused on the complementary role of structural policies in promoting more durable job-rich growth. In particular, the G20 has emphasized the essential role of structural reforms in ensuring strong, sustainable and balanced growth.

Against this backdrop, the 2014 Triennial Surveillance Review (TSR) called for further work to enhance the Fund's ability to selectively provide more expert analysis and advice on structural issues, particularly where there is broad interest among member countries. The purpose of this paper is to engage the Board on staff's post-TSR work toward strengthening the Fund's capacity to analyze and, where relevant, offer policy advice on macro-relevant structural issues.

While there is already an extensive range of work underway across the Fund, this paper lays out considerations to help frame a more strategic approach on structural issues that would better support the range of macro-structural needs of member countries. In that regard, this paper does not signal a dramatic shift in the Fund's agenda or coverage of structural issues; nor does it aim to provide a "how to" guide for advising countries on specific structural reforms. Instead, it focuses on "what" structural reforms are most likely to have macroeconomic implications, without attempting to do justice to the entire spectrum of issues that come under the structural reform umbrella.

To this end, the paper deploys a number approaches to identify reform areas most relevant across the membership.

- The empirical analysis finds a broadly positive relationship between structural reforms and productivity—in short, structural reforms matter. Importantly, the potential payoff from different reforms varies across income groups. The results also suggest that the benefits of reform tend to become more pronounced when reforms are bundled together.
- Given the need for care in interpreting the empirical findings, the paper also explores lessons from six country cases. Their reform experiences tend to reinforce the empirical findings and resonate with historical reform patterns. Moreover, these experiences hint at potential lessons for effective reforms, including the importance of strong ownership, the ability to sustain reforms, and the need for complementary macroeconomic and structural policies.

## STRUCTURAL REFORMS AND MACROECONOMIC PERFORMANCE

- These findings, together with an initial assessment of country needs, point to differentiated structural reform priorities across different country groups, reflecting stages of development. Nevertheless, some common reform priorities emerge where there is likely to be more broad-based interest across the membership.

Looking ahead, the approach and priorities identified in this paper can help guide the Fund in supporting countries' macrostructural policy needs. At an institutional level, the Fund's operational efforts should be geared toward countries' shared priorities. The Fund should continue to focus on structural reforms within its traditional areas of expertise—namely, fiscal structural and financial sector reforms. There are however other common priorities, outside of the Fund's traditional areas of expertise yet within its mandate, and where there is likely to be broad-based demand across the membership. In such areas, the Fund may need to scale up its efforts to build in-house expertise. In areas where there is less likely to be widespread demand across the membership, the Fund should actively collaborate with and leverage other institutions' expertise.

The goal is to develop a richer analytical foundation and range of tools—from within and outside the Fund—that country teams can leverage in their analysis and advice. Four complementary tracks of future work can help move this agenda forward: more systematically assessing country needs; ongoing analytical work; developing an analytical toolkit for staff; and developing modalities for inter-agency collaboration. This is not to say that Fund's macrostructural analysis and advice in individual cases should be limited to those areas. Ultimately, Article IV consultations should always be country-specific.

## Contributors

Prepared by SPR's Macrostructural team, comprising Swarnali Ahmed, Freddy Rojas Cama, Irineu de Carvalho Filho, M. Astou Diouf, Christian Gonzales, Minsuk Kim, Annette Kyobe, Karen Ongley (co-lead), Chris Papageorgiou (co-lead), Michael Perks, Hajime Takizawa, Evridiki Tsounta, Xin Cindy Xu. Sanjaya Panth and Taline Koranchelian provided general guidance.

The country case studies—Armenia, Australia, Malaysia, Peru, Tanzania, and Turkey—were prepared in collaboration with area departments.

The team is also grateful for additional assistance and inputs from SPR colleagues (Greg Basile, Alexander Culiuc, Ilse Peirtsegaele, Jiemin Ren, Chad Steinberg, and Joanna Zaffaroni), as well as area and functional departments in compiling information on recent Fund-wide analytical work on structural issues, and respondents to the survey of Fund mission chiefs.

## INTRODUCTION

**1. Structural policies have become increasingly central to the policy debate on how to strengthen countries' macroeconomic performance.** Since the global financial crisis, much of the Fund's membership has been grappling with how to break the cycle of lackluster growth and high unemployment, albeit with increasingly limited policy options. Moreover, the crisis has taken a toll on productivity growth, compounding the productivity slowdown that for many countries began well before the crisis. To this end, the policy debate has focused increasingly on the role of structural policies in boosting potential growth and economic resilience to promote more durable growth. The G20 has recognized "the essential role of structural reforms in ensuring strong, sustainable and balanced growth."<sup>1</sup> The Fund has also called for efforts to accelerate structural reforms as "an essential complement to demand-boosting efforts."<sup>2</sup>

**2. Against this backdrop, the Fund needs a strategic and analytically sound approach to effectively support the range of macro-structural needs across all member countries.** The 2014 Triennial Surveillance Review (TSR) set out broad principles to guide when and how the Fund should engage on structural issues. It also called for further work to boost our understanding of structural issues, building expertise where there is broad-based interest among member countries and improving the modalities for leveraging the expertise of other agencies where possible. There is already an extensive range of work underway across the Fund to examine the macroeconomic implications of structural reforms and raise awareness of country experiences. Looking ahead, the goal is to build on these efforts to more consistently integrate macro-structural issues in the Fund's day-to-day operations.

---

### **2014 TSR Recommendation:**

---

*"Be selective in advising on structural policies. Recognize all macro-critical structural issues and their implications on an economy; follow principles to determine where to provide advice: macro-criticality, and Fund expertise or interest from 'critical mass' of the membership (e.g., financial deepening and labor market issues); in other areas, leverage advice from other international organizations."*

---

**3. As a first step toward this broader agenda, this paper sets out considerations to help frame a more strategic approach.** The objective of this paper is not to signal a dramatic shift in the Fund's agenda or coverage of structural issues; nor does it aim to provide a "how to" guide for advising countries on specific structural reforms. Given the breadth and diversity of issues that come under the structural reform umbrella, one paper cannot do justice to the entire spectrum of issues. At this stage, the goal is to articulate more clearly, and give more analytical support to, the focus on particular structural reforms important for macroeconomic performance. In effect, this paper focuses on "what" structural reforms are, on average, most likely to have macroeconomic implications and thus be relevant for the Fund's dialogue with its members.

**4. Identifying the reform areas most relevant across the membership will help orient possible avenues of future work.** A central objective will be to provide a consistent and

<sup>1</sup> [G20 Communiqué](#), Meeting of G20 Finance Ministers and Central Bank Governors, 16-17 April 2015.

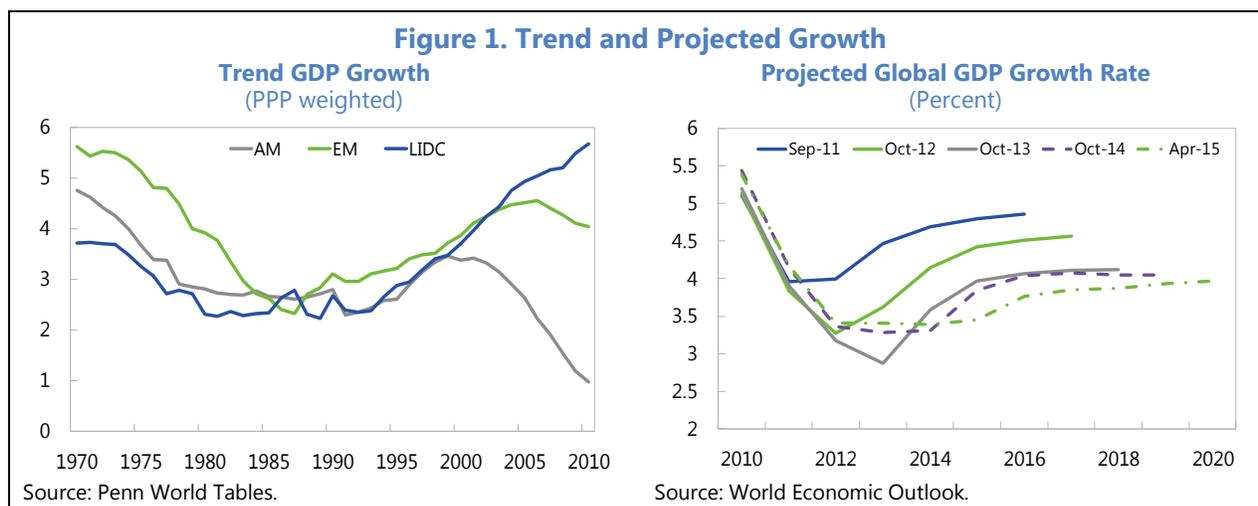

<sup>2</sup> [The Managing Director's Global Policy Agenda](#), Spring 2015.

evenhanded basis for engaging with member countries on structural issues—and, importantly, to avoid institutional overreach. Any approach should also be sufficiently flexible to ensure that the Fund’s policy analysis and advice reflects each country’s specific circumstances and needs. In this regard, the relationship between reforms and the macroeconomy are complex and varied, with a number of dimensions—covering direct and indirect implications for economic growth, stability, resilience and inclusion—that are potentially relevant for the Fund. Future work should therefore seek to understand more fully the needs of member countries, as well as delve more deeply into the macro-relevant effects of structural reforms and, where relevant, approaches to implementation.

**5. The paper is organized as follows:** Section II provides context on the evolving policy challenges for member countries and the increased attention to structural issues, including at the Fund; Section III presents stylized facts on the pattern of structural reforms over the past 30–40 years; Section IV assesses the relationship between structural reforms and productivity, including the relative benefits for different country groups as well as the implications of larger scale reforms and waves of contemporaneous reforms; Section V delves into the reform experiences of selected country experiences; Section VI explores considerations for the Fund’s operational approach to support the current reform priorities of member countries; Section VII discusses next steps in the Fund’s work on structural reforms; and Section VIII sets out possible issues for discussion.

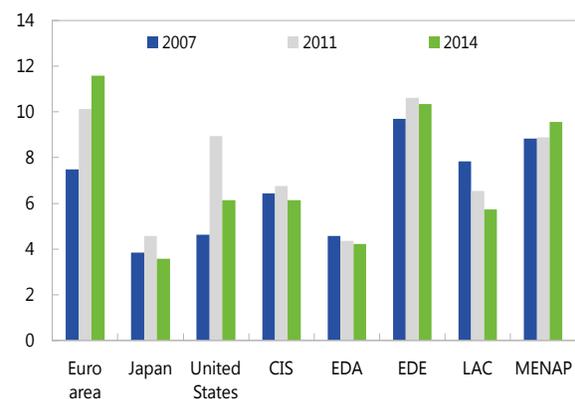

## THE POLICY CONTEXT

**6. Seven years after the onset of the crisis, a balanced, durable and job-rich recovery remains elusive.** Despite a rebound in global financial markets, global economic activity continues to disappoint. Since 2011, global growth has averaged around 3.5 percent, compared to an average of 4.2 percent between 1997 and 2006. The latest World Economic Outlook forecasts global GDP growth of around 3.1 percent this year, more than a percentage point lower than projected in September 2011 (Figure 1). At the same time, global unemployment remains stubbornly high at over 215 million people at end-2014, with particularly high rates in the Euro area, the Middle East and North Africa, and parts of Latin America (Figure 2).

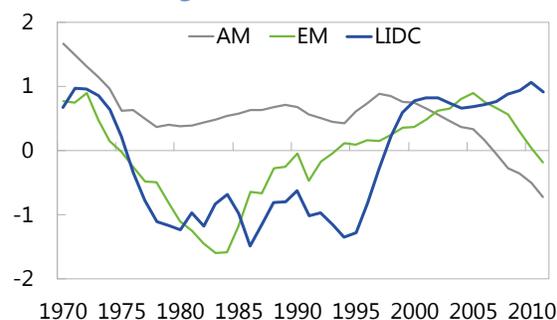

**7. Cyclical and structural factors are at play in this subdued global growth performance, although the slowdown in productivity growth has been a telling factor.** A sustained decline in potential output growth in advanced economies (AMs) began well before the crisis, driven largely by falling total factor productivity (TFP) growth and low employment growth (Figure 3). While the crisis further eroded TFP growth in the short-term, it also weighed heavily on investment and capital growth as well as potential employment growth, putting added downward pressure on potential growth among AMs. For emerging markets economies (EMs), lower TFP growth was also a key factor in the more recent decline in potential output growth, whereas potential employment and capital growth were largely unaffected by the crisis (Figure 4).<sup>3</sup> While potential output growth remains stronger in low-income developing countries (LIDCs), this tends to reflect factor accumulation rather than TFP growth. At the same time, for both EMs and LIDCs, the cyclical rebound from the crisis has also petered out. Domestic demand has

Figure 2. Unemployment Rate

<sup>3</sup> World Economic Outlook, Chapter 3, *Where are we Headed? Perspectives on Potential Output*, April 2015.

normalized and the favorable external environment that facilitated income convergence over the past decade—high commodity prices, low interest rates and buoyant trade—has weakened.

**8. With TFP growth faltering in many countries, weak actual and potential growth continue to cloud the outlook.** Only a moderate global recovery is envisaged over the medium term (Figure 5). Repeated markdowns in growth forecasts—mainly among AMs and EMs, but also some LIDCs—demonstrate the uncertainty surrounding medium-term projections and the risk of a “new mediocre” if secular stagnation takes hold in AMs and/or potential output growth is much lower-than-expected in EMs and LIDCs. Although AMs could see some recovery in potential output growth on the back of a small rebound in TFP, it will likely remain below pre-crisis rates for some time, held back by unfavorable demographics and subdued investment. In EMs, potential output is expected to decline further, with lower TFP, capital, and employment growth. Although potential output growth may continue to rise in LIDCs, TFP growth is expected to remain persistently flat—especially at a time when raising potential growth is essential to generate the jobs needed for the growing working age population.

**9. In this context, policymakers should continue to support demand where feasible, recognizing that policy support faces increasing constraints in many countries** (Figure 6). For AMs, the initial rounds of fiscal stimulus, and aggressive and unconventional monetary policies (UMP) were vital to jumpstart the recovery and prevent a financial system meltdown. As monetary policy rates approached the zero lower bound (ZLB), subsequent waves of UMP sought to further support the economy with bond purchases (QE). While circumstances vary among countries, the potential limits on demand-side policy space are, however, now becoming increasingly visible for much of the membership. The average debt-to-GDP ratio for AMs remains above 100 percent and will likely decline only very slowly in a slow growth, low inflation environment. Monetary policy rates remain close to the ZLB, even breaking into negative territory in some countries. Although of a different nature, EMs and LIDCs also have to contend with more limited macroeconomic policy space—for many inflation is above target, monetary policy rates are already low (or below neutral) and fiscal positions have weakened as a result of policies to counter the fallout from the crisis.

**10. Another consideration is that structural rigidities and market imperfections can also weigh on the effectiveness of demand-side policies and the efficient allocation of resources.**

UMP, particularly QE, proved crucial to supporting aggregate demand. And there is still unexploited scope in some countries for further demand support that need to be considered. However, over time the liquidity injected by central banks increasingly remains deposited as excess reserves, and corporates sit on large cash stockpiles. Complementary reforms to improve transmission mechanisms,<sup>4</sup> will help accommodative monetary policies become more effective in raising real investment. In contrast, overreliance solely on UMP can boost asset prices and generate financial stability risks. It is also telling that the recent confluence of generally favorable conditions—lower oil prices and the major depreciation in exchange rates—have yet to deliver a decisive boost to the real economy.

**11. Consequently, there is increasing interest in the role of structural policies in securing more durable and job-rich growth.** With faltering potential growth, persistent economic slack and, in some cases, constraints on demand support (both policy space and efficacy), structural reforms can be a critical component of a broader policy response. On the supply side, improving the allocation of resources and increasing investment can raise TFP—a key driver of actual and potential output growth. On the demand side, credible structural reforms can signal medium-term policy commitment, helping to build confidence and stimulate investment in the short term. Over time, structural reforms can also help to improve economic resilience. Stronger medium-term growth can improve debt dynamics, reinforcing efforts to rebuild policy buffers. Also, addressing underlying structural rigidities and the misallocation of resources can improve how an economy dynamically responds to shocks and to demand-support policies.

<sup>4</sup> For instance, insolvency reforms that incentivize the resolution of non-performing loans (NPLs) can help remove impediments to new lending.

**12. The channels through which structural reforms impact the macroeconomy are, therefore, varied and complex, not all of which are sufficiently understood.** For instance, initial conditions can be crucial for the impact of reforms—in terms of both size and duration—but there is no unanimity of views on exactly how. Similarly, regardless of initial conditions, while it is intuitive that the impact of some reforms is likely to accrue in the short term, for many others the effects are likely to accrue only over the medium- to longer-run. This all remains to be demonstrated in a sufficiently robust analytical framework, and the aim of this paper is not to take on these issues (although it could be a stream of future work). Rather the immediate objective, in line with the recommendations of the TSR, is to address an operational imperative—identify those structural reform areas that warrant more focus for the Fund.

**13. A strategic approach can help guide this effort and, in time, better position the Fund to effectively engage across the wide range of countries' reform needs.** Given the potential breadth of issues, we should be cognizant of the need to prioritize, and the Fund should continue to strive to better understand those reforms likely to strengthen macroeconomic performance and build economic resilience. That is not to imply that the Fund would prescribe a particular set of policies or take an overly narrow interpretation of macroeconomic relevance. To the contrary, the goal is to invest in analytical and operational approaches that continue to build a deeper understanding of the range of channels and macro-relevant effects of reforms. Over time, this would boost the Fund's capacity to deliver high-quality country-specific analysis and, where appropriate, advice. The Fund's mandate and *Articles of Agreement* can help guide these efforts, in line with its institutional responsibility (Box 1). At the same time, many structural issues will likely remain outside the Fund's areas of expertise, and exploiting opportunities for more effective collaboration with other agencies will be crucial to providing member countries with expert analysis in those areas.

**14. The Fund has already stepped up its efforts to better appreciate the macroeconomic implications of structural reforms.** This paper follows an extensive—and growing—analytical agenda both inside and outside the Fund (Boxes 2 and 3, respectively). A core element of the Fund's analytical work has focused on cross-cutting issues and assessing the impact of structural reforms on economic outcomes (such as, growth, productivity, employment, inequality). Other streams of work have targeted analyzing particular policy challenges or different types of reform (e.g., energy subsidy reform, labor market policies, fiscal structural reforms, infrastructure investment, insolvency reform, or financial deepening), and often as they relate to economic challenges faced by individual countries, groups of countries or regions. In this regard, bilateral and multilateral surveillance are playing an instrumental role in deepening the Fund's understanding of the relationship between structural reforms and macroeconomic performance. This, in turn, provides a stronger basis to leverage cross-country knowledge of policy experiences, while ensuring Fund analysis and policy advice is tailored to country circumstances.

### Box 1. Basis for Fund Engagement on Structural Issues<sup>1/</sup>

**The primary goal of the IMF is to promote global economic and financial stability.** Article I of the *Articles of Agreement* sets out the purposes of the Fund and its role in supporting the rules and mechanisms for stability of the international monetary system; as well as facilitating the expansion and balanced growth of trade, and thereby contributing to the goal of member countries to promote and maintain high levels of employment and income.

**Surveillance—with its core organizing principle of stability—is central to achieving this objective.**<sup>2/</sup> To this end, multilateral surveillance pertains to global or regional economic and financial stability, and can encompass a wide range of country policies to the extent that they have wider spillovers. Bilateral surveillance focuses on an *individual* country's domestic and balance of payments stability and, as such, it always assesses exchange rate, monetary, fiscal and financial sector policies. However, it should also be tailored to reflect country circumstances and thus can cover other policies that have implications for stability. While growth is not strictly a goal of bilateral surveillance, in practice it often falls within its scope given the extent to which it can affect stability.<sup>3/</sup>

**There are several channels through which structural issues could have a bearing on stability.** For instance:

- *Impeding the efficient allocation of resources within an economy could contribute to the buildup of imbalances.* For example, impediments to competition and protection of the non-tradable sector can inhibit the development of the tradable sector and lead to an unsustainable external position.
- *Limiting flexibility could prevent timely adjustment to shocks and weaken the resilience of an economy.* For example, labor market rigidities (especially with regard to wage setting, unemployment benefits, severance pay) can contribute to high unemployment and low productivity growth. Similarly, impaired private sector balance sheets (with NPLs and debt overhang) can hold back lending and investment, constraining the pass-through of easier financial conditions.
- *Constraining potential, and eventually actual, growth can undermine stability.* For example, investment bottlenecks that constrain productivity and output growth can contribute to unfavorable debt trajectories, deteriorating financing conditions, and financial sector instability.
- *Generating imbalances in a member country or group of countries that impact global economic and financial stability.* For example, weak investment in AMs, infrastructure bottlenecks in EMDCs and deficiencies in LIDCs, can collectively weigh on short-term global demand and medium-term global growth prospects.

**Assessing the implications of structural issues for stability requires judgment, taking into account country circumstances.** The [Guidance Note for Surveillance under Article IV Consultations](#) outlines different approaches to inform these assessments, including: analysis to identify key growth bottlenecks and their macroeconomic impact; or assessing how far an economy stands from its efficient frontier to pinpoint areas with the greatest growth impact. The Guidance Note also offers approaches to assessing outward spillovers for systemic economies.

**Structural reforms can also often be relevant in the context of Fund-supported programs.** Given that Fund financing is focused on addressing balance of payments needs, program conditionality covering structural issues is expected to be limited to the minimum necessary to address those issues that are of critical importance to achieving the program's goals or for monitoring program implementation. Coverage is therefore tailored to country circumstances, reflecting understandings between the Fund and country authorities.<sup>4/</sup>

**The Fund's capacity building activities can also involve structural issues and policies.** While this typically involves technical assistance in established areas of Fund expertise (e.g., fiscal structural reforms), it continues to evolve. For instance, since 2000 the Fund has also offered technical advice to improve countries' Anti-Money Laundering and Combating the Financing of Terrorism (AML/CFT) regimes.

<sup>1/</sup> Prepared in consultation with LEG.

<sup>2/</sup> Article IV (Section 3) provides for the Fund's oversight of: (i) each member's compliance with its surveillance obligations under Article IV, Section 1 (*bilateral surveillance*); and (ii) the international monetary system to ensure its effective operation (*multilateral surveillance*).

<sup>3/</sup> Policy advice provided in the context of surveillance can also cover other issues and policies, if they are important objectives for the member or if specifically requested by the member.

<sup>4/</sup> See [2011 Review of Conditionality](#).

## Box 2. Overview of the Fund's Recent Analytical Work on Structural Issues<sup>1/</sup>

Following the global financial crisis, the Fund has produced a tremendous volume of analytical work on structural issues. This work encompasses a wide variety of issues, ranging from cross-cutting reforms relevant to the broader membership to reforms specific to particular regions, country groups or levels of development.

A key goal has been to deepen the Fund's understanding of how structural reforms affect economic outcomes, including: (i) boosting incomes and economic efficiency (e.g., investment, labor/product market reforms); (ii) promoting fairness and equity (e.g., tax and subsidy reform, social spending, gender equality); (iii) fostering economic and financial stability (e.g., export diversification, financial supervision, insolvency regimes, management of capital flows); and (iv) improving quality of life (e.g., education, healthcare, climate issues).

The Fund has engaged in broad cross-cutting work examining how structural reforms affect economic growth and productivity as well as poverty, inequality, and environmental issues.

- **Economic growth and productivity.** The Fund has examined how [real and financial sector reforms](#) impact economic performance in advanced and developing countries, and how structural reforms impact [productivity growth](#) in aggregate and by sector according to a country's development.
- **Inclusive Growth and Gender.** The IMF has focused increasingly on aspects of [inclusive growth](#), including different regional considerations. The Fund also conducts an annual survey on [access to finance](#) and has studied the role of [financial inclusion](#) in promoting more inclusive growth. Fund staff has also looked at the macroeconomic gains from [closing gender gaps](#) in labor markets, including through addressing constraints on [female labor participation](#), as well as drawing lessons from country experiences (such as in India, Hungary, Japan, the Nordic region, South Korea, and Saudi Arabia).
- **Climate.** In this area, the Fund's work focuses on the fiscal, financial, and macroeconomic impact of climate issues (e.g., via work on [water management](#), and [carbon taxes and fiscal policies](#) to mitigate climate change).

The Fund has also examined how structural reforms in particular sectors can boost output and efficiency.

- **Labor and product markets.** The Fund has analyzed the relationship of jobs and growth, emphasizing the need to tackle high unemployment. This analysis is often tailored to particular regions, such as reforms to help reorient employment from the public to private sector in [Gulf Cooperation Council countries](#) or monetary, debt and labor market reforms to help [create jobs in Europe](#). Structural issues have also featured prominently in [surveillance in Europe](#), including exploring the governance aspects of [structural reforms](#) and [fiscal structures](#) in the Euro Area.
- **Public investment and infrastructure.** In this area, staff analysis has found that [increased public infrastructure investment](#) raises output in both the short and the long-term, particularly when there is economic slack and the efficiency of investment is high. [Other work](#) shows that, given the potential for waste and inefficiency, better management of investment could close up to two-thirds of the efficiency gap.
- **Fiscal structural reforms.** The Fund has explored how fiscal reforms can support [strong and equitable growth](#), including how policies (such as stabilization, tax and expenditure policies, and institutional reforms) can boost labor supply, investment in physical and human capital, or productivity. Other analysis has covered reforms related to [fiscal frameworks](#), [tax administration](#), [public financial management](#) and [pension systems](#).
- **Managing natural resources and subsidy reform.** The Fund has examined economic policies to [manage natural resources](#), including [in collaboration with aid agencies](#). The IMF has also prepared comprehensive estimates of the fiscal, environmental, and welfare costs of [energy subsidy reform](#).
- **Trade.** Looking beyond trade liberalization, the Fund has sought to identify structural aspects that can promote growth and stability. This includes studying how economies in [emerging Europe](#) and [Asia](#) can take advantage of global value chains, and how [export diversification](#) can raise growth in low-income countries.

<sup>1/</sup>See Annex I for an illustrative list of recent Fund analytical work.

### Box 3. The Wider Literature on Structural Reforms—What Have We Learned So Far?<sup>1/</sup>

This box presents a snapshot of the vast and growing literature on the macroeconomic effects of reform.

Academic interest in reforms and their role in macroeconomic performance picked up during the 1990s as many countries embarked on broad economic reform programs, often triggered by deteriorating economic conditions (Drazen and Easterly, 2001), including external debt crises and recessions (Agnello et al., 2015). However, there is no fixed relationship between the drivers of structural reforms and their actual implementation. Each country's experience reflects its institutional characteristics, history and political systems (Haggard and Webb, 1993). Moreover, the packaging and pace of economic reforms often reflects not just technocratic considerations, but the process of building broad political support and the outcome of bargaining among interest groups.

Over time, the literature evolved from its focus on cross-country long-run growth analyses to more micro-level studies that better address causality. More recently, DSGE models are gaining popularity due to their capacity to quantify more complex effects related to reform interactions and dynamics. Empirical evidence from the literature generally supports that structural reforms enhance economic performance, although the estimated effects and channels vary depending on the type of reform and country-specific conditions.

Turning to individual areas, a large body of work finds that *financial sector reforms* have positive effects through more efficient allocation of resources (MacKinnon, 1973; Shaw, 1973; King and Levine, 1993; Galindo et al., 2005) and easier access to external financing (Rajan and Zingales, 1998). Some have argued that *stock market liberalization* leads to higher investment and output growth (Henry, 2000; Bekaert et al., 2005), whereas findings on the effect of *capital account liberalization* more broadly are less clear-cut (Eichengreen, 2002) and could depend on the income level of a country (Klein and Olivei, 2008). Early literature on *trade liberalization* yield mixed results (Rodríguez and Rodrik, 2000), but recent studies provide more support to the positive effects (Dollar and Kraay, 2004; Wacziarg and Welch, 2008; Estevadeordal and Taylor, 2013). The quality of *legal system*, and in particular *property rights*, is also found to have an important effect on long-run output and investment growth (Acemoglu and Johnson, 2005).

An emerging strand of research focuses on the link between growth and market regulation. A large number of studies using rich micro-level datasets find robust evidence that competition-promoting *product market reforms* help boost an economy's total factor productivity growth (Nicoletti and Scarpetta, 2003; Faini et al., 2006; Buccirossi et al., 2009; Bourles et al., 2013). The benefits of *labor market deregulation*, on the other hand, appear more mixed (OECD, 2007) and smaller than from product market reforms (Bouis and Duval, 2011). Nonetheless, some recent studies find that strict employment protection depresses productivity growth (Bassanini et al., 2009), and high unemployment benefits and tax wedges can negatively affect employment (Bassanini and Duval, 2009).

The issue of reform complementarities—arising from “packaging” multiple reforms—is a small but fast-growing area of research. Several studies find that the strength of legal and political institutions affect long-run growth through their influence on financial sector development (La Porta et al., 1997; Demirguc-Kunt and Maksimovic, 1998; Acemoglu and Johnson, 2005; Djankov et al., 2005; Beck et al., 2005; Prati et al., 2013; Christiansen et al., 2013). Other work examines potential interactions between product market distortions and labor market rigidities (Blanchard and Giavazzi, 2003; Jean and Nicoletti, 2003), providing some indication that product and labor market reforms could complement each other and thus have far-reaching effects beyond their respective markets. Based on results from a DSGE model, Cacciatore et al. (2012) suggest implementing a broad package of labor and product market reforms to minimize short-term transitional costs associated with certain types of reforms (e.g., job protection reform).

Finally, studies on the sequencing of reforms remain at an early stage, with further work needed to draw useful policy insights. Hauner et al. (2013) show that trade reforms tend to precede domestic financial reforms, rather than *vice versa*, confirming Rajan and Zingales' (2003) prediction that opposition to financial sector reform weakens when an economy allows greater trade flows. Bouis et al. (2012) find that reforms may have varying impact over the business cycle, suggesting that undertaking some reforms (e.g., labor market) in good times, rather than in bad times, may help limit short-term implementation costs.

<sup>1/</sup> See Annex V for a full list of references.

## STRUCTURAL REFORM PATTERNS & STYLIZED FACTS

*Understanding how structural reform efforts have evolved across countries and over time can provide a useful starting point for better appreciating the macroeconomic benefits and considering possible operational implications for the Fund. Although structural reforms are more difficult to measure than typical macroeconomic policies, efforts to develop indicators make it possible to observe longer-term reform patterns across the membership and among country groups. Trends over the past several decades suggest that reform efforts have often borne a close relationship with macroeconomic conditions, stages of development and global integration.*

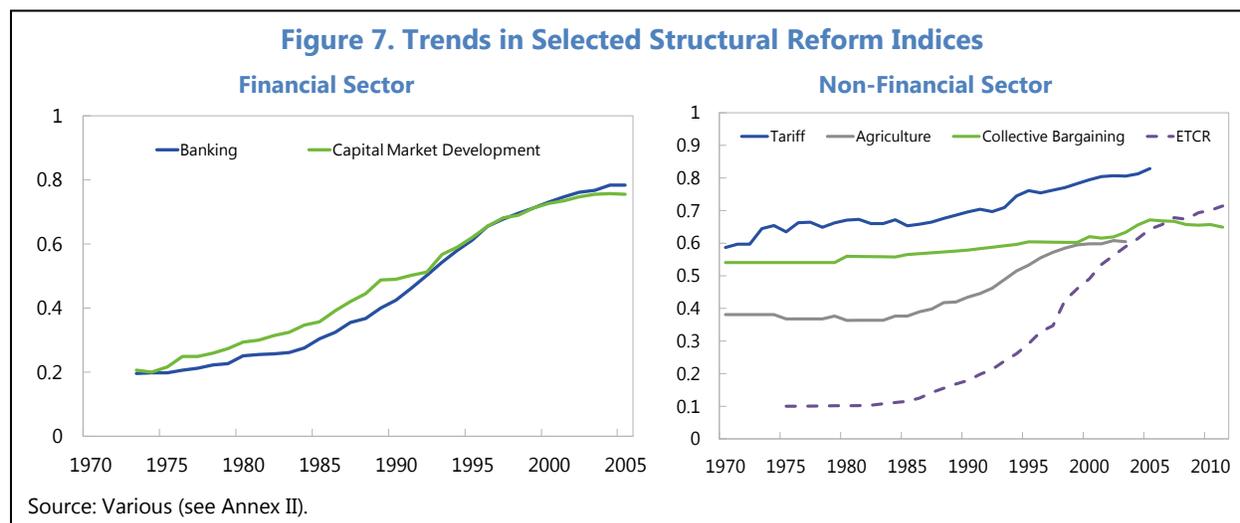

**15. Structural reforms are inherently difficult to measure as they often involve policies or issues that are not easy to quantify.** They typically concern policies geared towards raising productivity by improving the technical efficiency of markets and institutional structures, and by reducing or removing impediments to the efficient allocation of resources. Thus, structural reforms have typically been associated with regulatory policies aimed at strengthening market-based incentives in domestic product and service markets, labor markets, trade, and capital and financial markets among others. However, structural reforms may also involve actions to address market failures (such as the increased emphasis on effective financial sector regulation since the crisis) or other government policies that can affect productivity more directly. In this regard, the recent Board paper on *Fiscal Policy and Long-term Growth* noted that fiscal policy can play a role, including where private provision may be less efficient in allocating resources (e.g., infrastructure) or where private markets do not adequately capture positive externalities (e.g., research and development).

**16. The priority for this paper has been to examine reform patterns and relationships based on reform indicators that are broadly representative of the entire Fund membership.** The database covers 108 countries—33 AMs, 53 EMs, and 22 LIDCs—during the period 1970–2011 (see Annex II). It covers structural reforms in 10 areas, ranging from trade and financial sector reforms to institutional reforms, as well as reforms relating to the functioning and regulation of markets. Comparable indicators of fiscal structural reforms, beyond those noted above, are currently not available.<sup>5</sup> However, the emphasis here is to apply a consistent analytical approach to a sufficiently large sample, covering all income groups.

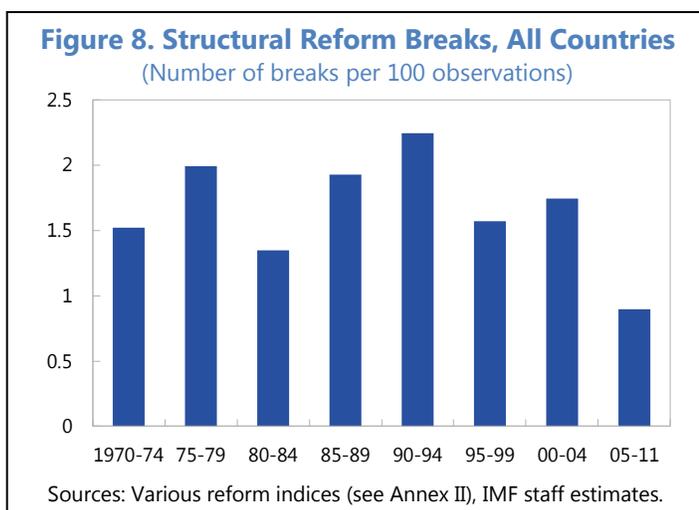

**17. These indicators suggest that the Fund’s member countries, at all levels, have undertaken substantial structural reforms over the past 30–40 years** (Figure 7). With few exceptions, most reform indices have trended up since the 1970s. The most pronounced and sustained advances have taken place in banking and other financial sector reforms, although there are also clear positive reform trends in agriculture, trade and industry. Performance in other areas is more mixed, with limited progress in infrastructure, and more sporadic efforts in legal system and

<sup>5</sup> The Board paper on [Fiscal Policy and Long-term Growth](#) examined extensively fiscal reforms using an alternative framework and we draw on the findings of that analysis in later aspects of this paper.

labor market reforms. However, a deeper look at the pace of reforms across different indices or country groups provides a richer picture.

**18. The strongest reform momentum tended to coincide with periods of economic stress or turbulence.** We identify big reform episodes based on the largest annual improvements in reform indices (top 3 percent) sustained during a three-year window (Figure 8). The *first big reform push* took place in mid-1970s, with a surge in reform efforts in the period following the breakdown of the Bretton Woods system and the first oil price shock. A *second big push* occurred during the late 1980s and early 1990s on the heels of the Latin American debt crisis and when many countries moved into recession after the 1987 stock market crash. Reform efforts gathered steam again during a *third big push* in the late 1990s and early 2000s around the time a number of EMs experienced financial crises. This pattern appears to be broadly consistent with literature that suggests that sustained or acute economic weaknesses often catalyze concerted structural reform efforts (see Box 3).

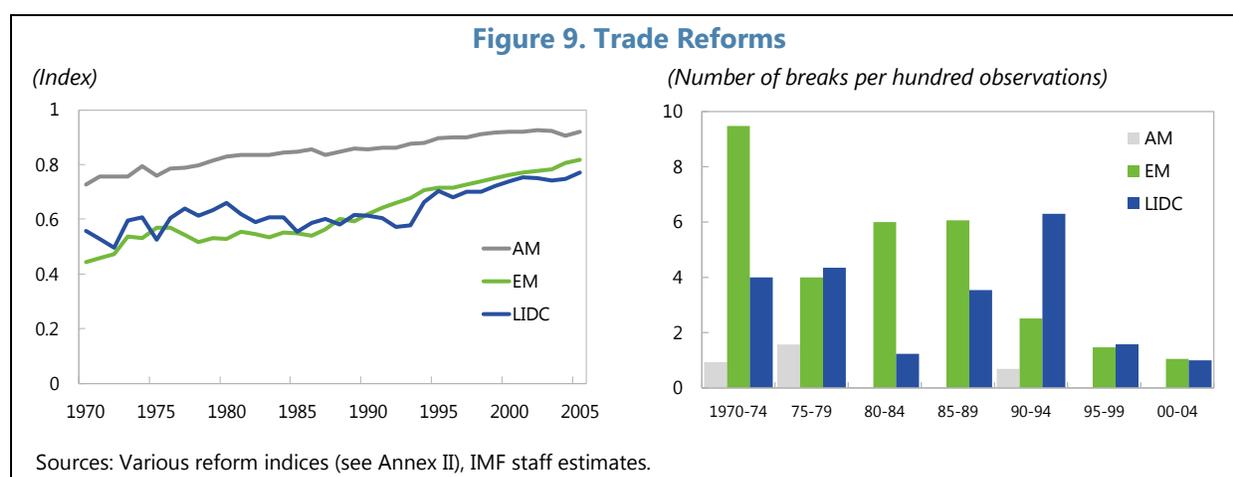

**19. Reform patterns in several areas also tend to mirror the acceleration in global economic and financial integration.** In particular, *trade reforms* initially appear to have been undertaken in the context of multilateral and regional trade negotiations (Figure 9). EMs were perhaps most aggressive in pursuing trade reforms in the 1970s and 1980s, as many gradually phased out import substitution policies and pursued export-led growth models. Trade reform got a further boost from LIDCs from the second half of the 1980s to the mid-1990s. However, the

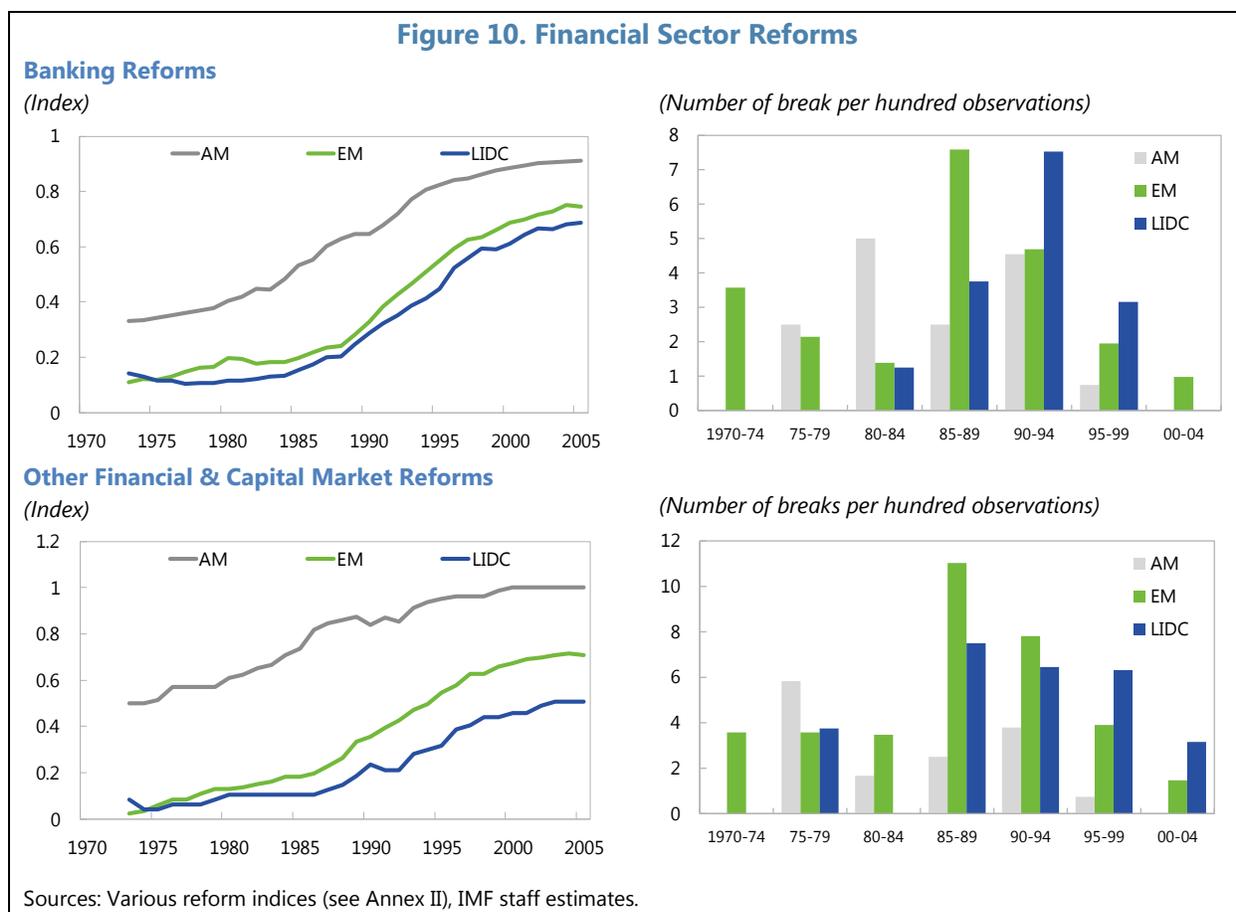

increased potential for international competition or spillovers from, and the desire to take advantage of, a globalized economy have created incentives to pursue broad-based reforms beyond basic trade liberalization.<sup>6</sup> In this regard, the staggered take-off of *banking* and *capital market reforms* also appears broadly consistent with the pattern of international financial integration—first picking up among AMs in the 1970s, then by EMs a decade later, and in turn LIDCs with the gradual development of their domestic financial sectors (Figure 10).

## 20. However, certain reform patterns seem more attuned to evolving circumstances faced by countries—in particular, their stage of development.

- Early reforms by EMs and LIDCs focused on building stronger institutional foundations—*legal system and property rights* and *infrastructure*—although efforts have waned in some areas. AMs have not made progress on infrastructure since the 1970s, possibly reflecting large scale investment in earlier period and, thus, the recent increased attention to infrastructure (e.g., G20).
- In the wake of falling agricultural prices, and also possibly reflecting increased trade integration, *agricultural reforms* accelerated in EMs and particularly LIDCs from the mid-1980s through the 1990s.
- The global trend towards increased transparency and accountability may well have increased the emphasis on *business environment reforms* by AMs in the 1990s and more recently by EMs. Reforms by EMs in this area also reflected their broad structural transformation. These reforms were followed by more sophisticated *labor market reforms* in the 2000s, with efforts focused on decentralizing collective bargaining and reforming hiring and firing regulations.
- *Industry reforms* by AMs and EMs picked up in the second half of the 1990s, an era of rapid technological innovation (e.g., telecommunications) and the search for new energy sources.

<sup>6</sup> For example, see Sachs and Warner (1995).

## ASSESSING THE IMPACT OF STRUCTURAL REFORMS

Observing broad reform patterns, however, can only take us so far. If the Fund is to invest more systematically in supporting countries' reform needs, this requires a deeper and more robust appreciation of the relationship between reforms and macroeconomic performance. In this instance, we focus on productivity, finding a broadly positive relationship with structural reforms—one that tends to become more pronounced when reforms are bundled together. However, going forward, the Fund should continue to explore a range of channels and effects to paint a more comprehensive picture of the relationship between reforms and macroeconomic performance.

**21. While structural reforms can be expected to affect macroeconomic performance through a variety of channels, productivity warrants attention at this juncture.** In particular, TFP is a significant driver of output (Figure 11).<sup>7</sup> Given the secular decline in productivity, worsened by the crisis, raising productivity is an essential piece of today's policy puzzle—both in boosting potential growth and economic resilience. Moreover, the impact of reforms on employment and capital accumulation are worthy of attention in their own right, and have been covered in more

<sup>7</sup> By decomposing levels of GDP per capita, Hall and Jones (1999) and Duval and de la Maisonneuve (2010) found that differences in productivity are a key determinant of cross-country variations in output per capita.

detail in other Fund analysis (Annex I), but for the purposes of this paper, they are implicitly captured when we consider growth in testing the robustness of our findings on productivity. While the remainder of this paper focuses on productivity, it will be essential for the Fund to continue exploring the impact of structural reforms on other macroeconomic variables. There is particular merit in looking at other effects as they pertain to specific reforms or are of special relevance to a region or group of countries (e.g., labor market reforms and employment).

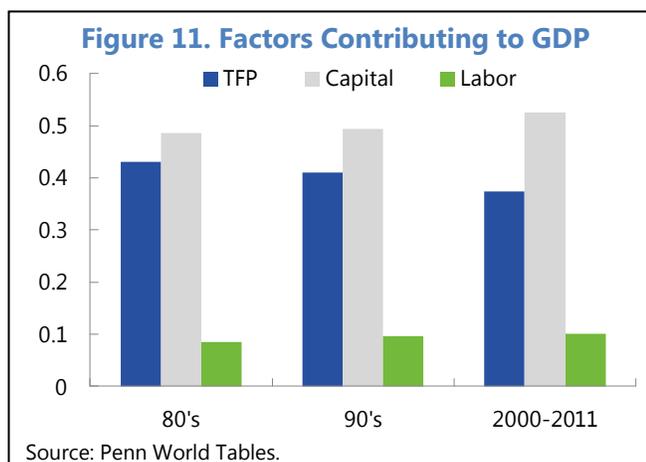

**22. Several different empirical approaches yield broadly similar conclusions regarding the relationship between structural reforms and productivity.**<sup>8</sup> Building on previous Fund

work, the analysis first explores the relationship between broad *reform trends* and productivity for all country income groups, including whether the impact varies across reforms and different country groups. Second, it considers if and how large-scale individual reforms (episodes) affect the results. Finally, it assesses the impact of *implementing several reforms in parallel* (waves) and whether the results differ from individual reform episodes.

### A. Steady Reform Trends

**23. The results from our first exercise point to a broadly positive relationship between different types of reforms and productivity growth.** Using panel regression analysis, we estimate the impact of different types of structural reforms one year forward on TFP growth for countries at different stages of development. The results (Table 1) are broadly aligned with the historical reform patterns (previous section), as well as a range of previous Fund work.<sup>9</sup> They are also consistent with an intuitive understanding of the relationship between reforms and stages of economic development.

**24. In this regard, we find that the potential payoff from different reforms varies across country groups.** For instance, reforms to the legal system and property rights show a positive association with productivity growth in LIDCs and EMs, but not in AMs. In contrast, labor reforms (such as those concerning conditions related to hiring and firing and collective bargaining) are

<sup>8</sup> The structural variables used in this analysis are presented in Annex II and are the same as those for which stylized facts are presented in the previous section. The various empirical approaches are described in Annex III.

<sup>9</sup> See, for example, [The New Normal: A Sector-Level Perspective on Productivity Trends in Advanced Economies](#); Dabla-Norris, et al. (2015); [Anchoring Growth: The Importance of Productivity-Enhancing Reforms in Emerging Market and Developing Economies](#), Dabla-Norris, et al. (2013); [Structural Reforms and Economic Performance in Advanced and Developing Countries](#), IMF Occasional Paper No. 268 (2008); and "Which Reforms Work and under What Institutional Environment? Evidence from a New Data Set on Structural Reforms," *Review of Economics and Statistics*, Vol. 95:3 (July), pp. 946-968, Prati et. al., 2013.

## STRUCTURAL REFORMS AND MACROECONOMIC PERFORMANCE

associated with higher productivity growth in EMs and AMs, but not in LIDCs. In this regard, the varying magnitudes and significance of coefficients highlight differences in the potency of structural reforms across country groups.

**25. Applying the same approach to other key macro-indicators also suggests a positive relationship with the same set of reforms.** Cognizant of the broader notion of macroeconomic performance, we undertook a battery of checks and balances, testing different specifications and variables.<sup>10</sup>

- This included, for instance, examining the strength of the productivity-reform relationship with longer lags, as well as looking at the relationship between reforms and output and investment growth. The positive relationship holds up under these checks—in particular, substituting GDP growth for TFP growth generates similar results—providing reassurance of a robust relationship with productivity and the macroeconomic relevance of reform more broadly.
- In a similar vein and in keeping with the Fund’s focus on stability, a separate track of ongoing work exploring the relationship between reforms and external resilience is generating early favorable results (see Box 4).

Source: IMF staff estimates.

<sup>10</sup> The alternative specifications included using longer lags of reform indices. The entire set of robustness checks are described in Annex III.

- An additional check to assess the long-run impact of reform on productivity suggests that reform priorities within each group (LIDCs, EMs, AMs) are broadly similar with our baseline results. There are a few exceptions. Over the long-run, the loosening of hiring and firing regulations has a less pronounced impact for AMs and EMs. On the other hand, several reforms have a stronger long-term impact: infrastructure (all country groups), bank supervision (EMs), capital market development (LIDCs), and decentralizing the collective bargaining process (EMs).

#### Box 4. Structural Reforms and External Resilience<sup>1/</sup>

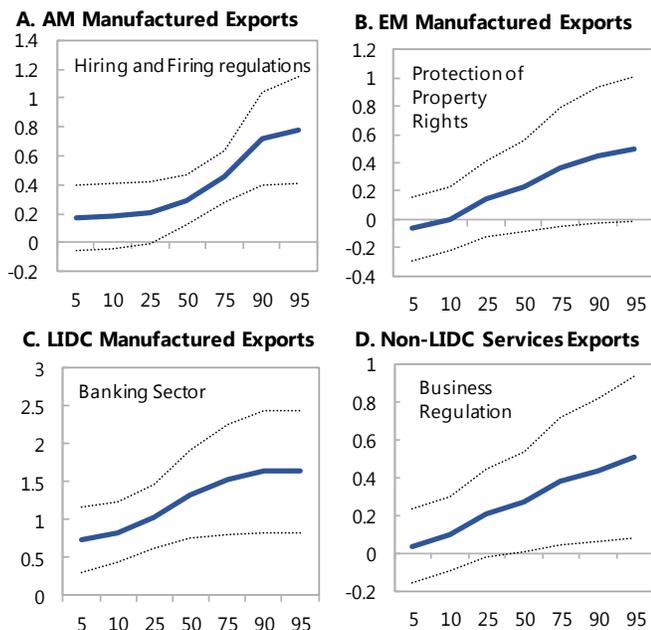

**Structural reforms can help countries adjust to shocks, thus contributing to economic stability.** There are numerous channels through which structural reforms can speed up the response to economic signals, thus improving resilience. We focus on the resilience to shocks propagated through the real exchange rate. More resilient economies should exhibit a higher export response to real depreciations. *Labor and product market reforms* remove impediments to the allocation of resources to the tradeable sector. A *sound financial sector* facilitates this reallocation by channeling resources needed to finance the adjustment. Strong *legal systems* can mitigate risks associated with the transition, which would otherwise lead to underinvestment. *Trade openness* ensures that missing inputs are readily available.

**We analyze the impact of structural indicators on the exports' response to REER movements** using cross-country panel regressions that allow for estimating the percentage change in exports in response to a one percent change in the REER.<sup>2/</sup> This

slope—called the *elasticity of exports with respect to the REER*—denotes the sensitivity of exports to movements in the exchange rate, with a steeper slope indicating a higher sensitivity. The hypothesis is that the slope (elasticity) should increase as structural indicators improve, i.e. countries with better structural indicators should respond more to a given REER depreciation. Since different structural indicators are likely to be binding at different income levels (e.g., reflecting differences in economic structures), we also expect different types of indicators to matter across income groups.

**The measured elasticity increases as structural indicators improve.** The text figure shows how elasticities change across the distribution of select structural indicators across countries. For example, panel A shows that an AM moving from the 25<sup>th</sup> to the 75<sup>th</sup> percentile of the distribution in terms of hiring and firing regulations will see its export elasticity for manufacturing goods increase from 0.2 to 0.45, i.e. its exports will have twice as large a response to a given REER depreciation.

#### Export Elasticities Across Structural Indicators

Note: Horizontal axis is percentile distribution of countries in respective income group across the structural indicator. The dotted lines indicate the 95 percent confidence interval.

### Box 4. Structural Reforms and External Resilience (cont.)

**The specific reforms that matter differ across income groups.** The text table summarizes the magnitude and statistical significance of the impact of various structural indicators on export elasticities across income groups.<sup>3/</sup> Key findings, in the case of manufactured exports, are as follows:

- *In advanced economies*, product and labor market regulations are the primary facilitators of the manufactured exports' response to REER movements.
- Institutional indicators are important in *emerging markets*, which is consistent with the prominent role played by cross-border supply chains, which heavily rely on a strong contracting environment.
- *In low income countries*, banking sector regulations have a strong effect on export elasticities.<sup>4/</sup>

The table also presents results for *services exports* using Balance of Payments data for AMs and EMs. We find that services exhibit strong responses to REER movements in the presence of flexible financial sectors, trade openness, strong legal systems and property rights.

It should be noted that caveats regarding the main results of this paper (for example concerning reform complementarities and endogeneity; see paragraph 30. ) also apply here.<sup>5/</sup>

#### Impact of Structural Reforms on Export Elasticities

	Manufactured exports			Services
	AMs	EMs	LIDCs	Non-LIDC
<b>Financial sector</b>				
Banking	+	-	+**	+***
Security Markets	+**	-	+	+***
<b>Openness</b>				
Tariff rates (average)	+	-	+	+***
<b>Institutions</b>				
Protection of property rights	+	+**	-	+**
Legal enforcement of contracts	-	+*	+	+**
<b>Product market regulation</b>				
Business regulations	+**	+	-	+**
Telecom & electricity regulation	+	-		+
<b>Labor market regulation</b>				
Hiring & firing regulations	+**	+		-
Centralized collective bargaining	+	+		-

Note. The table presents the sign of the  $\beta_2$  coefficient (see Footnote 1). Plus denotes larger elasticities in absolute terms. \*, \*\* and \*\*\* denote significance at the 10, 5 and 1 percent levels respectively.

<sup>1/</sup> This box summarizes selected results from ongoing analytical work on structural reforms and external resilience.

<sup>2/</sup> The estimated equation is  $\Delta \log X_{it} = \beta_1 \Delta \log REER_{it-1} + \beta_2 \Delta \log REER_{it-1} \times S_{it-1} + \beta_3 S_{it-1} + \beta_4' Z_{it} + \omega_i + \eta_t + \varepsilon_{it}$ , where  $X_{it}$  is exports of country  $i$  in period  $t$ ,  $S$  is the structural reform of interest,  $Z$  is a set of control variables (trading partner growth and export goods inflation),  $\omega$  and  $\eta$  capture country and time fixed effects, respectively. We use the negative of CPI REER change, i.e. a depreciation has a positive sign. The effect of the structural indicators on the export elasticity is captured by the  $\beta_2$  coefficient on the interaction term. The equation is estimated on both manufactured and services exports using data averaged over three years. Most regressors are lagged to alleviate endogeneity concerns.

<sup>3/</sup> While some structural indicators are shown with a negative sign, not one of them is statistically different from zero.

<sup>4/</sup> A somewhat limited number of observations for LIDCs suggests a more cautious treatment of corresponding results.

<sup>5/</sup> A number of robustness checks were performed, including controls for the structure of the export basket (measured by the Economic Complexity Index), and different averaging periods (1 and 5 years).

## B. Large-Scale Reform Episodes

**26. Large-scale reforms also demonstrate a generally positive relationship with post-reform productivity growth.** To complement the regression analysis of general reform trends, we use positive ‘breaks’ in reform indices to identify large-scale reform episodes (i.e., the top three percent of positive changes). With a few exceptions, we find that reform episodes are typically associated with a significant pick up in post-reform productivity growth rates (Table 2). These simple computations broadly reinforce the findings of the regression analysis (including patterns relevant reforms across country groups).

However, these results also suggest that the pace or magnitude of reform could have implications for the potential benefits, although not all large-scale reforms have commensurately large impacts on productivity.

**27. Differences in the post-reform pickup in productivity growth underscore the need to calibrate the pace of reform depending on the reform type and the country group.** For instance:

- For some reforms, *more gradual implementation* may be likely to yield benefits, whereas rushed large-scale spending may have little or no benefits—or even have negative consequences. In the case of infrastructure, for example, Berg et al. (2012) show that in developing countries, large public investments financed by natural resource booms can undermine investment efficiency. A similar challenge may arise for AMs investing in knowledge capital (R&D spending).

**Table 2. Average Medium-term TFP Growth Gain After Breaks**

## STRUCTURAL REFORMS AND MACROECONOMIC PERFORMANCE

- Other reforms may be more amenable to a positive relationship with productivity growth when implemented through a “big bang” approach, rather than a more gradual manner. Here too, the results vary among country groups. For instance, “big bang” reforms in agriculture or the policy environment for foreign investment appear to be more valuable for EMs than slow and steady reforms in these areas.

### C. ‘Waves’ or Bundling of Reforms

**28. Even larger productivity payoffs are observed when multiple reform episodes occur in parallel.** In practice, reforms in different areas can, and often do, occur simultaneously or in “waves.” To examine whether reform “waves” further enhance the positive relationship with productivity, we consider instances when 3 or more large-scale reform episodes in different areas are implemented within the same 3-year period.<sup>11</sup> In these instances, there is a substantial uptick in 5-year average TFP growth rates after reform “waves” (Figure 12).<sup>12</sup> Specifically, AMs and EMs exhibited an average 2 percentage point pick-up in productivity growth, while LIDCs saw a much higher 5.5 percentage point increase. These productivity gains outstrip those associated with individual reform episodes.

**29. The magnitude of these productivity growth differentials supports the notion that reforms can have complementary effects.** While further work is needed to confirm this empirically, the common recurrence of particular reforms in “waves” adds credence to this notion. Among 34 identified reform “waves,” comprising 103 episodes, these most often included financial sector reforms (both banking system and capital market development). The prevalence of banking and capital market reforms in waves may well reflect the central role that the financial sector plays in efficiently allocating resources. The next most common reforms to occur in waves were legal system and trade reforms. For example, episodes of capital market reforms are often accompanied by strengthening the broader legal system and property rights.

### D. Interpret with Care

**30. While these broadly consistent empirical results provide some measure of comfort, the results should be interpreted with some caution.** The analysis above extracts useful information

<sup>11</sup> See Annex III for more details.

<sup>12</sup> For this calculation, we take the first year of the 3-year window as the reference point.

from the available data, but is not without some limitations. The first concerns data availability—there are certain types of structural reforms for which data is not available in a form amenable to regression analysis. Second, while the empirical results highlight statistical associations between the various types of reforms and productivity, they do not conclusively establish causality. Third, the regression results do not account for reform complementarities because the high correlation in reform indices requires them to enter the regressions one at a time. Fourth, measured TFP may also fall temporarily, introducing a downward bias on the results when the ultimate impact of the reform is still positive. The transition literature, for example, shows that reform often coincides with sharp declines in measured output as part of creative destruction—capital in inefficient places is idled, relative prices change, and resource reallocation incurs large initial costs.<sup>13</sup> Finally, while the empirical work considers one-year-ahead impacts and shows the results to be broadly robust to using longer lags or when considered over the longer-term, the objective of the analysis is not to establish the relationship between reforms and their time to impact, or between reforms and initial conditions. Having said that, the results do, however, suggest some promising areas for future research on these questions.

## SELECTED COUNTRY EXPERIENCES

*Given the need for care in interpreting these empirical findings, countries' reform experiences offer additional insights to help provide a more well-rounded basis for enhancing the Fund's approach to structural reforms. The six country cases examined for this paper tend to reinforce the messages from the empirical analysis, suggesting that sustained and well-coordinated reforms typically coincide with periods of improved productivity and macroeconomic performance more generally. Moreover, these experiences—as well as instances where reforms have proved less successful—hint at potential lessons about the ingredients for effective implementation and favorable outcomes.*

**31. Member countries' reform experiences are essential to developing a deeper understanding of the macroeconomic benefits of structural reform.** In this regard, the Fund is working to better leverage its existing country-based analytical work and share knowledge of cross-country reform experiences (e.g., see Box 2 and Annex I).<sup>14</sup> Continuing in this spirit, we examine six country cases to glean potential lessons to enrich the Fund's approach to structural reform issues and its engagement with member countries. The group of countries comprises: Armenia, Australia, Malaysia, Peru, Tanzania and Turkey.<sup>15</sup> In some instances, these cases consider longer term reform efforts in the context of structural transformation (e.g., Malaysia). Others focus on more concentrated reform periods (e.g., Peru in the 1990s). In addition to complementing the empirical

<sup>13</sup> See, e.g. Harvylyshyn, Izvorsky and van Rooden, 1998; Blanchard and Kremer, 1997.

<sup>14</sup> For example, the recent Board paper on [Fiscal Policy and Long-term Growth](#) (April 2015) incorporated a range of country case studies.

<sup>15</sup> This group includes at least one country from each income level and each geographic region. These cases are set out in a companion paper, [Structural Reforms and Macroeconomic Performance: Country Cases](#).

analysis in this paper, the potential lessons from countries' different approaches to designing and implementing reforms can point to avenues of future research and analysis.

**32. Acute economic pressures or crises are often a strong motivation for countries to undertake structural reforms.** For instance, Malaysia introduced an ambitious structural reform package, the *National Economic Recovery Plan*, to address the Asian crisis legacies of slow growth and financial system fragility. Similarly, Tanzania and Turkey undertook reforms in the wake of very weak growth, high inflation, and serious balance of payments pressures. In Armenia, the dissolution of the Soviet Union spurred a comprehensive rethink of the country's economic model. Australia was an exception, with broad-based structural reforms following a protracted period of mediocre growth. These experiences resonate with the broad trends and impetus from reforms in recent decades as noted in paragraph 18.

**33. In turn, concerted structural reforms have generally coincided with a turnaround in economic performance.** In each of these country cases, TFP growth picked up during the identified reform periods, in tandem with improved macroeconomic fundamentals. There was, however, some variation in the acceleration of TFP growth and the extent to which more favorable TFP growth was sustained following reforms. The more successful periods witnessed broad based macroeconomic benefits, with improvements in GDP growth and real GDP per capita—importantly, this pattern was evident for AMs, EMs, and LIDCs alike. Moreover, reforms arguably enabled some countries to be more resilient to shocks. For instance, around the time Australia was weathering the Asian crisis, Peru also withstood a series of external shocks between 1998 and 2001.

**34. These country cases send a strong signal about the likely conditions for undertaking successful reforms.** Importantly, structural reforms in and of themselves are not a 'silver bullet' for macroeconomic success. Strong ownership and the ability to sustain reforms appear to be crucial to reaping the productivity and growth benefits. Indeed, without sustained reforms, improvements in macroeconomic performance may be short-lived. In this regard, the domestic political context and the ability to garner strong and broad-based buy-in appear to be critical in being able to implement complementary macroeconomic and structural reforms, to make effective choices about combining and sequencing reforms, and to mitigate the risks of reform reversals.

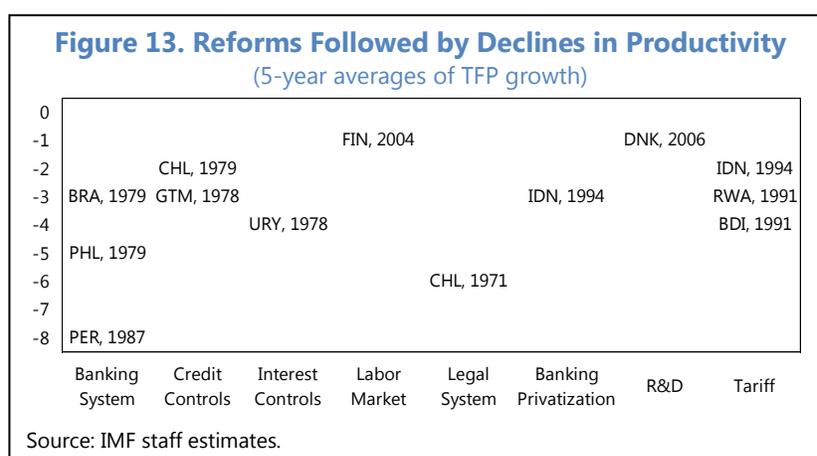

- While most specific reforms were undertaken over a short period of time, successful reforms were typically implemented in sequence and as part of a 'wave' of reforms intended to reinforce and complement one another. In this regard, the benefits of one-off reforms were less apparent than of reform 'waves.' Moreover, the pattern of reforms appeared to evolve in a broadly similar way across countries and over time. Typically, trade and price liberalization (including in the banking sector) were implemented first (Armenia, Australia, Tanzania, Malaysia and Turkey), followed by privatization and banking supervision and legal reforms.
- The most successful reform periods reflected a more comprehensive approach, where sound macroeconomic policies were an essential complement to structural reforms. As macroeconomic stresses (e.g., high inflation in Turkey) can derail growth prospects despite sustained structural

reforms, credible fiscal and monetary policy frameworks are a vital ingredient to successful outcomes (Armenia, Australia, Malaysia and Tanzania).

- In this regard, almost all cases of fiscal structural reforms played a pivotal role in stabilizing the macroeconomic situation. Most often this involved a combination of measures to strengthen tax administration, spending efficiency and fiscal frameworks (e.g., Armenia, Australia, Malaysia, and Peru).

### 35. Circumstances where structural reforms have not yielded success can be equally

**instructive.** The reform indices used in the empirical analysis also allow us to identify cases where TFP growth has shown negligible improvement or has even been negative following reforms. Figure 13 shows instances where reforms were followed by periods of negative TFP growth. In order to help member countries design and implement future reforms, it is important to understand the factors underlying those unfavorable outcomes. In many instances, these lessons reinforce those from the reform successes, including the need to understand specific country circumstances in order to calibrate the timing, pace and sequencing of reforms.

- Given that sustained reforms are more likely to generate prolonged benefits, the design of reform packages should account for macroeconomic stability and domestic political economy considerations. While large external shocks or crises provide an opportune time to implement reforms, they can also have damaging effects to existing reform efforts. Similarly, political economy factors are essential elements in enacting and sustaining reforms (Hoj, 2006).
- Binding constraints to economic performance can vary across countries (Hausmann et al., 2005), reinforcing the need to tailor reforms to country circumstances. Christiansen et al. (2009) find that weak institutions could be one such constraint for reaping the benefits of reforms. Macroeconomic stability can also be a binding constraint (Lora and Panizza, 2002), reinforcing the point above about the merits of sound macroeconomic policies or, where needed stabilization policies accompanying structural reforms.
- How quickly or extensively to reform is a pivotal decision. Some argue that lack of success is because reforms either did not go far enough or, at the other extreme, were too dramatic (Zettelmeyer, 2012). This is evidenced in our break analysis where most, but not all large reforms, had a substantial positive impact on productivity. However, it underscores the need for countries to effectively prioritize and pace reforms. It also highlights the risk of viewing reforms

in a too linear or simplistic fashion—in many instances, unconstrained liberalization can be problematic. For instance, prior to Chile’s reform successes, the improvement in TFP growth following banking reforms in the 1970s was short-lived (Figure 13), possibly reflecting too rapid or unbalanced reforms (e.g., weak supervision in the new deregulated financial market). These lessons were reflected in subsequent banking reforms that were more measured, and included supervisory reforms as a core element.

## REFORM NEEDS AND OPERATIONAL PRIORITIES

*Country experiences and different approaches to reform—such as the apparent merits of waves of reforms—suggest that prioritization is a central consideration for effective implementation. Given the breadth of structural reforms that can benefit macroeconomic performance, it is essential to begin to understand how countries might prioritize their reform efforts. Efforts to identify member countries’ current reform needs suggest that the Fund is already focusing on reforms most likely to have macro-payoffs. Looking ahead, this can also help inform efforts to build a macrostructural toolkit to support country-tailored analysis and deeper engagement with member countries.*

### A. Member Countries’ Current Reform Needs

**36. For the Fund to appropriately orient its efforts, it is important to have a clear sense of the structural issues currently foremost on policymakers’ minds.** As a preliminary step toward a more systematic “bottom up” diagnosis of countries’ structural reform challenges, a recent survey of IMF mission chiefs<sup>16,17</sup> sought to gauge the extent to which different types of structural issues are most relevant for member countries’ macroeconomic performance.

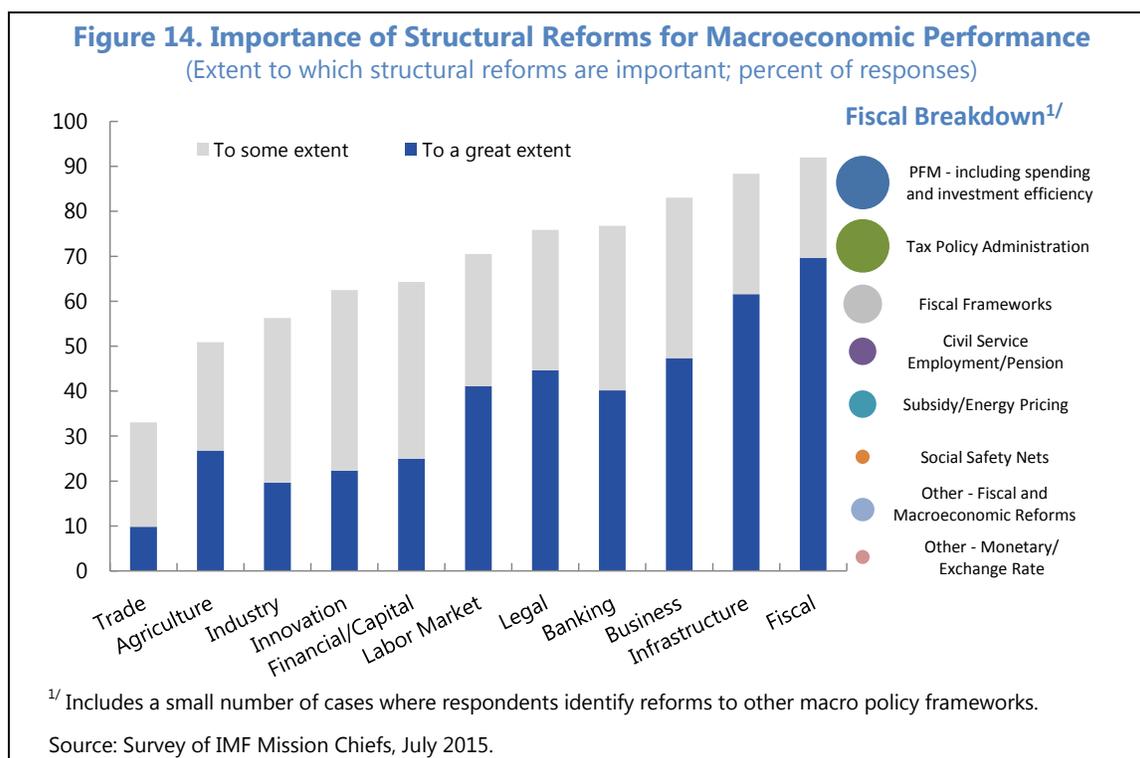

**37. The survey results confirm that a wide range of structural reforms are regarded as having a bearing on macroeconomic performance.** While all reform categories considered in the context of the empirical analysis above were considered to be macro-relevant, seven of these categories were considered to be macroeconomically important by over two-thirds of respondents (Figure 14). The wide interest in banking and other financial market reforms is consistent with the increased focus on financial stability since the crisis, including aspects related to cross-border flows and spillovers, and the growing role of non-banks. The same could be true of labor market issues in light of persistently high unemployment and the need to generate job-rich growth. The strong interest in infrastructure and legal system reforms is largely driven by EMs and LIDCs. Similarly, compared to the broader membership, fragile states place more importance on agriculture, legal and business reforms, and infrastructure.

<sup>16</sup> In July 2015, staff conducted a survey of IMF Mission Chiefs for the Fund’s 188 member countries. The average response rate was around 60 percent, with a response rate above 50 percent for mission chief’s representing all regions and income groups. Further information on the survey questions and response rates are set out in Annex IV.

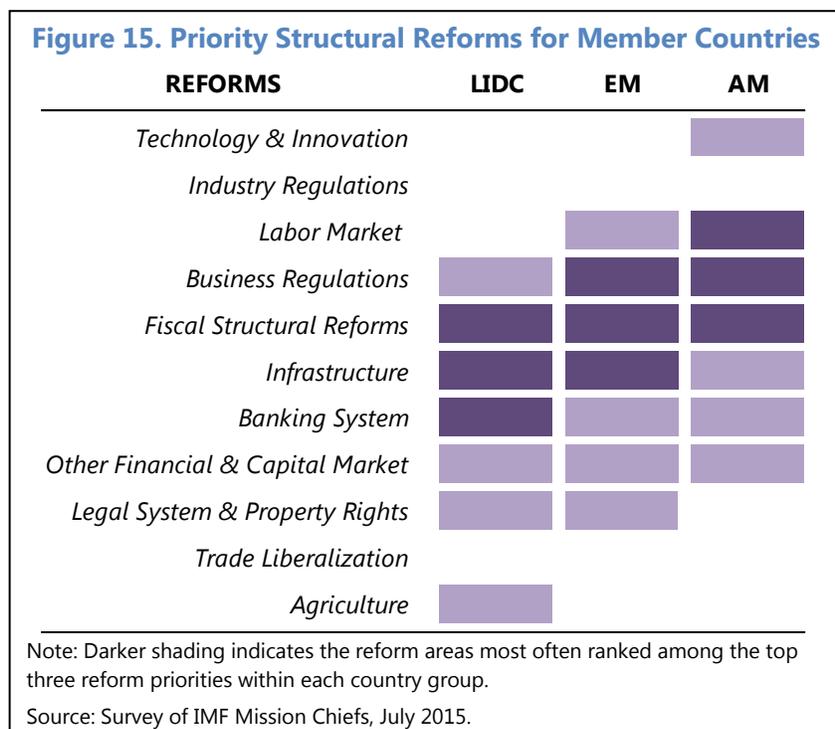

<sup>17</sup> While the survey results offer insights into the potential range of macro-relevant structural issues, they should be regarded as preliminary and not be taken to represent the views of country authorities.

**38. Fiscal structural reforms are also considered by almost all respondents to be important for macroeconomic performance** (over 90 percent), in keeping with the Fund's core business.

While this reflects a range of different types of fiscal reforms, three areas dominated: tax administration; public financial management and spending efficiency; and fiscal frameworks. There was broad recognition of the macro-importance of tax policy administration reforms across all income groups. However, EMs tended to see more value-added in reforming fiscal frameworks. Also, while LIDCs emphasized the importance of public financial management reforms, AMs and EMs focus on more general aspects of spending and investment efficiency. Although subsidy and energy pricing reforms were rated somewhat lower on average, these tended to be a higher priority for EMs and LIDCs, as well as oil/commodity producing economies.

**39. The highest priority reforms identified by respondents suggest that structural reform needs evolve across different stages of development** (Figure 15). On the one hand, the survey responses reveal several common reform priorities across all member countries. In addition to a strong common interest in fiscal reforms (noted above), there is a shared interest in banking and other financial and capital market reforms, infrastructure, and the business environment. As inferred by the earlier empirical analysis and country cases, the different priority reforms tend to reflect different stages of economic development. For instance, agricultural reforms appear to be relatively more important among LIDCs, and legal system reforms more important among LIDCs and EMs, whereas labor market issues become more relevant for EMs and AMs, and only AMs prioritize technology reforms.

**40. The few instances where priority reforms diverge from historical reform patterns or country experiences appear to reflect the evolving nature of economies.** For instance, following concerted trade liberalization reforms by LIDCs in recent decades, their reform efforts may be more focused on other aspects of trade reform (such as export diversification and integrating with global value chains). Similarly, AMs have a renewed interest in other financial market reforms given the growing role of non-banks and considerations related to expanding the regulatory perimeter. This suggests that the Fund is already focused on those reforms likely to have the highest payoff for macroeconomic performance, with due regard for changing circumstances and country specificities.

## B. The Fund's Operational Focus on Structural Reforms

**41. Looking ahead, the Fund's operational efforts should be geared to better supporting countries' macro-relevant reform needs.** Our engagement with individual countries should be tailored to the reform priorities most relevant for their specific macroeconomic circumstances. However, to avoid an ad hoc approach, the TSR recommended a principles-based approach to help guide and articulate the macro-relevance of structural reforms. More broadly, the TSR emphasized the desirability of delivering more expert analysis and advice. To this end, institution-wide efforts should be geared toward developing and leveraging high quality and expert analysis and advice on structural issues, guided by three broad principles.

- One, the Fund should be equipped to *recognize* all macro-critical structural issues and highlight the macroeconomic implications in its surveillance.

- Two, although the Fund should limit its policy *advice* to areas where it has the necessary expertise, there may be merit in cautiously building further expertise in selected macro-critical areas of high impact and high demand—avoiding institutional overreach and guided by the rationale in Box 3.
- Three, where structural reforms have macro-implications, but remain clearly outside the Fund’s core areas of expertise, the Fund should explore opportunities to better leverage or strengthen interagency collaboration mechanisms to draw on appropriate outside expertise.

The macro-structural relationships outlined in this paper—both empirical and country-based—can inform judgments about implementing these principles, and prioritizing the Fund’s efforts.

**42. The earlier empirical analysis can help gauge the relative benefits of different reforms for each country group, providing a starting point toward operationalizing these principles.**

Table 1 provides a basis for such an exercise—it indicates the relative impact of each type of reform across country groups, but not the impact of different reforms within any given country group. To take this extra step, it is useful to consider the “distance-to-best practice” for countries in each group, defined as the gap between the top performer in each group and the bottom 25<sup>th</sup> percentile in each reform index. Multiplying this gap by the initial regression coefficients (Table 1) provides an estimate of the expected productivity payoff from

closing this reform gap in each country group (Table 3). As the gap does not depend on the particular scaling system of any reform index, this allows the estimated productivity gains to be compared across reform indices. In effect, this indicates the relative effectiveness of each reform in delivering higher productivity growth for each country group (where the darker shades imply relatively larger gains).

**43. The reform priorities that emerge resonate with the historical reform patterns and country reform experiences examined earlier.**

- Differing priorities among country groups suggest that reform needs evolve as an economy develops. For instance, the relatively important reforms for LIDCs—such as *agriculture*—are consistent with early stages of development when economies are more agricultural and markets are less well developed. Structural reforms that produce the largest TFP growth gains for EMs focus on improving market functioning as they become more industrialized—e.g., *business regulation*. For AMs, priority reforms are geared toward supporting more technologically advanced economies, with more well developed labor and product markets—*innovation* (particularly for those closest to the technology frontier) and *labor market reforms*.
- At the same time, two common priorities emerge from this exercise. *Infrastructure* and *banking reforms* both have the potential for high productivity payoffs in all country groups, reflecting their centrality to the effective functioning of any economy. However, differences among the various aspects of *banking reforms* signals the importance of a more nuanced (or non-linear) interpretation. A wider range of banking system reforms are important for EMs and LIDCs, perhaps as they stand to benefit most from fundamental reforms and financial deepening. Reforms to banking *supervision*, on the other hand, are the priority for AMs, underscoring the importance of adopting balanced and holistic reforms, rather than simply pursuing liberalization unchecked.

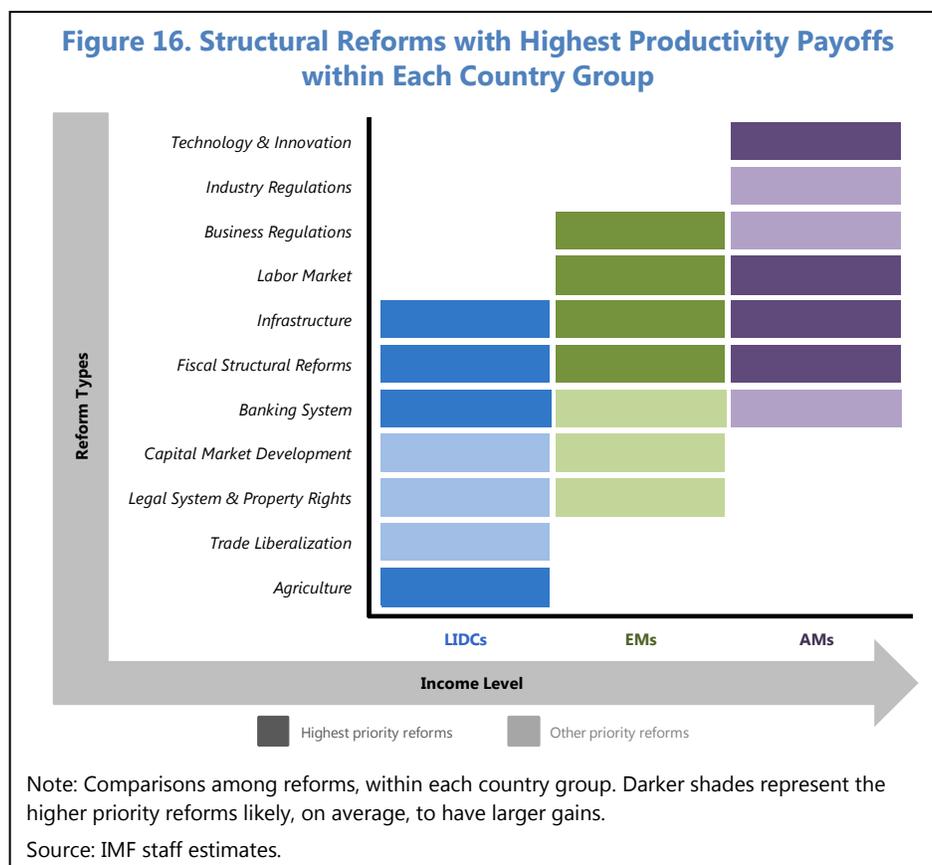

**44. Beyond these empirically driven priorities, there is strong evidence that fiscal structural reforms are also a top priority.** Where there is clear evidence from other sources, the Fund’s operational approach should not be constrained by available reform indices. This is the case, in particular, with fiscal structural reforms. The country case studies demonstrated the importance of fiscal structural reforms for macroeconomic performance,<sup>18</sup> as well as the broader success of countries’ structural reform efforts. Similarly, the survey results point to strong demand across the entire membership in this area. The Fund’s existing expertise and depth of knowledge in this area ensures that it has been, and will continue to be, the principal provider of expert analysis and advice in many aspects of fiscal structural reform across all parts of the membership.

**45. Collectively, this can inform how member countries and the Fund think about prioritizing structural reforms issues.** It makes intuitive sense that countries focus on those reform

---

<sup>18</sup> The paper on [Fiscal Policy and Long-term Growth](#) also reiterated their importance for growth, and offered concrete suggestions on priority tax and expenditure policies that can help promote growth (see Table 1 of that paper).

areas likely to yield the largest payoffs. For the Fund as well, it is critical to prioritize, not just in tailoring its country-level analysis and advice, but in deciding at an institutional level where to build capacity and where to rely on other institutions (cognizant of both resource constraints and the Fund’s mandate). The reform priorities draw from the range of approach above—empirical, as well as survey- and country-based—can be presented in a stylized “heatmap” of structural priorities (Figure 16) that could help guide the Fund’s operational priorities in this area. While these reforms may not always reflect individual priorities, it provides a basis for considering where, on average, there is most value in the Fund “building” versus “borrowing” capacity.

**46. In addition to *which* reforms to prioritize, this paper touches on aspects of reform implementation that merit attention in future analytical work.** For instance, the pace of reform appears to matter for productivity growth as much as the type reform. Similarly, there appear to be benefits in implementing multiple reforms simultaneously (‘waves’). While these are intuitively sensible lessons, further analytical work is needed to understand these issues more fully (e.g., which reforms at which pace, or which reforms are best bundled together in ‘waves’). Over time, these factors will help inform decisions about how to translate the ‘heatmap’ to individual country circumstances.

## IMPLICATIONS AND NEXT STEPS

**47. The analysis presented above can help guide the Fund in supporting countries' macro-structural policy needs in several ways.** At an institutional level, this helps to direct the Fund's efforts towards reforms that, on average, are likely to offer the global economy the best chance of securing higher and more durable growth. Thus, this approach provides a basis for collaborating with other agencies and in guiding where the Fund may wish to enhance its own capacity to provide advice. This is not to say that macrostructural analysis and advice in individual cases should be limited to those areas, or indeed that they necessarily should even cover those areas. Ultimately, Article IV consultations should always be country-specific. Thus, the primary goal of the 'heatmap' and this institutional approach is to develop a richer analytical foundation and range of diagnostic tools—either from within the Fund or from partnering institutions—that country teams can leverage in their analysis and advice.

**48. The analysis allows us to identify more clearly those reform areas to which the Fund's operational efforts should be geared.**

- The Fund has a clear comparative advantage and should continue building upon it in fiscal structural and financial sector reforms—at the center of the 'heatmap' (Figure 16). As the only multilateral institution focusing on macroeconomic policy with near universal membership, the Fund should continue to take primary responsibility for providing expert analysis and advice in these areas.
